Let it now be required to find the perspective P of a point P, (figs. 1 and 2) in the ground plane. We draw through P first lines of which the projection can easily be found. The most convenient lines are the perpendicular to the base line, and a line parallel to it. These are easily drawn, and also the line through P at right angles to the ground plane is RD. These two lines meet at P, which is the point required. It will be noticed that the line QR = QK = QP passes through the point P behind the picture plane. Hence if we know the point Q where a perpendicular from a point in one plane meets the picture plane, and the distance of the point behind the picture plane, we can find its perspective. We join Q to V, set off QR to the right equal to the distance of the point behind the picture plane, and join R to the point to give the distance to the left where cuts QR is the point required. Or we set off QR' to the left equal to the distance and join R' to the distance point D' to the right.

If the distance of the point from the picture should be very great, the point R might fall at too great a distance from Q to be on the drawing. In this case we might set off QW equal to the nth part of the distance and join it to a point E, so that VE equals the nth part of VT. Thus if QW = QR and VE = VD', then VE will be QW through P. It is thus possible to find for every point in the ground plane, or in fact in any horizontal plane, the perspective;
PERSPECTIVE

for the construction will not be altered if the ground plane be replaced by any other horizontal plane. We can in fact now find the perspective of every point as soon as we know the foot of the perpendicular drawn from it to the picture plane, that is, if we know its position on the picture plane, and the distance from it. For this reason it is often convenient to draw in slight outlines the elevation of the figure on the picture plane.

Instead of drawing the elevation of the figure we may also proceed as follows. Suppose \( A \) to be the projection of the plane of a point \( A \). Then the point \( A \) lies vertically above \( A \) because vertical lines appear in the perspective as vertical lines (§1). If then the line \( AV \) cut the figure at \( Q \), and we erect at \( Q \) a perpendicular in the picture plane to its base set off on it \( OQ \) equal to the real height of the point \( A \) above the ground plane,

then the point \( A \) is the elevation of \( A \) and hence the line \( AV \) will pass through the point \( A \). The latter thus is determined by the intersection of the vertical line through \( A \) and the line \( AV \).

The method mentioned before is that the construction for finding the point is not made in the horizontal plane in which it lies, but that its plan is constructed in the ground plane. But this has a great advantage. The perspective of a horizontal plane through a figure to the line of sight in the picture the space between the line where the plane cuts the picture and the horizon, and this space is the greater the farther the plane is from the eye, that is, the farther its trace on the picture plane lies from the horizon. The horizontal plane through the eye is projected into a line, the horizon; hence no construction can be performed in it. The ground plane on the other hand is the lowest horizontal plane used. Hence it offers most space for constructions, which conse-quence will allow of greater accuracy of the operations.

§5. The process is the same if we know the co-ordinates of the point, viz. we take in the base line a point \( O \) as origin, and we take the base line, the line \( OV \), and the perpendicular \( OZ \) as axes of co-ordinates. If we then know the co-ordinates \( x, y, z \) measured in these directions, we make \( OQ = x \), set off on \( OQ \) a distance \( DA \) such that its real length \( QR = y \), make \( QA = z \), and we find \( A \) as before. This process might be simplified by setting off to begin with along \( OQ \) and \( OZ \) scales in their true dimensions and along \( OQ \) a scale obtained by projecting the scale on \( OQ \) from \( D \) to the line \( OV \).

§6. The methods explained give the perspective of any point in space. If lines have to be found, we may determine the perspective of a plane, and join the points of intersection most convenient process. Often, however, it will be advantageous to determine the projection of a line directly by finding its vanishing point. This is especially to be recommended when a number of parallel lines have to be drawn with greater accuracy of the operations.

The perspective of any curve is in general a curve. The projection of a conic is a conic, or in special cases a line. The perspective of a circle may be any conic, not necessarily an ellipse. Similarly the perspective of the shadow of a circle on a plane is some conic.

§7. A few words must be said about the determination of shadows in perspective. The theory of their construction is very simple. We may say, a light source of light and the point \( C \) a vertical plane. This will cut the floor in a line which contains the feet \( A, C \) of the perpendiculars drawn from the points \( A, C \) to the floor, or the planes of these points. At \( C \), where the line \( AC \) cuts \( AB \) will be the shadow of \( C \) on the floor. If the wall \( EGH \) prevents the shadow from falling on the floor, we determine the intersection \( K \) of the line \( AC \) with the base \( EF \) of the wall and draw a vertical through it, this gives the intersection of the wall with the vertical plane through \( A \) and \( C \). Where it cuts \( AC \) is the shadow \( C_2 \) of the wall.

If the shadow of a screen \( CDD' \) has to be found we find the shadow \( D' \) of \( D \) which falls on the floor; then \( D_2D' \) is the shadow of \( D \) and \( D' \) is the shadow of the floor on the line \( DC \). The shadow of \( D_2D \), however, is intercepted by the wall at \( L \). Here then the wall takes up the shadow, which must extend to \( D' \) as the shadow of a line on a plane is a line. Thus the shadow of the screen is found in the shaded part in the figure.

§8. If the shadows are due to the sun, we have to find first the perspective of the vanishing point of its rays. This will always be a point in the picture plane; but we have to distinguish between the cases where the sun is in the front of the picture, and so behind the spectator, or behind the picture plane, and so in front of the spectator. In the second case only does the vanishing point of the rays of the sun actually represent the sun itself. It will be a point above the horizon. In the other case the vanishing point of the rays will lie below the horizon. It is the point where a ray of the sun through the centre of sight cuts the picture plane, or it will be the shadow of the eye on the picture. In either case the ray of the sun through any point is the line joining the perspective of that point to the vanishing point of the sun's rays. But in the other case it falls towards it. The direction of the sun's rays may be given by the plan and elevation of one ray.

For the construction of the shadow of points it is convenient to use \( E \), and let it be required to find the shadow of the vertical column \( AH \). We draw \( A_d, E \), and the other parallels. We have then \( E'F'C'G' \) will be the shadow of the quadrilateral \( EFGH \). For the shadow of the column we take \( E' \) to \( A, C \), but only mark the outlines; \( F', B, D' \), the shadow of \( B, D \), does not appear as such in the figure.

If the shadow \( E \) has to be found when falling on any other surface we use the vertical plane through \( E \), determine its intersection with the surface, and find the point where this intersection is cut by the line \( EL \). This will be the required shadow of \( E \).

§9. If the picture is not to be drawn on a vertical but on another plane, as the ceiling of a room—windows given have to be slightly modified. The general principles will remain true. But if the picture is to be on a curved surface the constructions become somewhat more complicated. In the most general case conceivable it would be necessary to have a representation in plan and elevation of the figure required and of the surface on which the projection has to be made. A number of points might also be found by calculation, using co-ordinate geometry. But into this we do not enter. As an example we take the case of a panorama, where the surface is a vertical cylinder of revolution, the eye being in the axis. The ray projecting a point \( A \) cuts the cylinder in two points on opposite sides of the eye, hence geometrically speaking each point has two projections; but only the one lying on the half ray from the eye to the point can be used in the picture. But the other has sometimes to be used in constructions, as the projection of a line has to pass through both. Parallel lines have two vanishing points, for any ray passing through one line is a shadow of the other through the eye; it cuts the cylinder in the vanishing points required. This operation may be performed by drawing on the ground the plan of the ray through the foot of the axis, and through the point where it cuts the horizontal circle. The vanishing points must lie. Its height above is easily found by making a drawing of a vertical section on a reduced scale.

Parallel planes have in the same manner a vanishing curve. This will be for horizontal planes a horizontal circle of the height of the eye above the ground. For vertical planes it will be a pair of generators of the cylinder. For other planes the vanishing curves will be ellipses having their centre at the eye.

The projections of vertical lines will be vertical lines on the
PERSPIRATION—PERTH

259
cylinder. Of all ether lines they will be ellipses with the centre at the eye. If the cylinder be developed into a plane, then these ellipses will be changed into curves of sines. Parallel lines are thus represented by curves of sines which have two points in common. There is no difficulty in making all the constructions on a small scale on the drawing board and then transferring them to the cylinder.

§ 10. A variety of instruments have been proposed to facilitate perspective. If the problem is to make a drawing from nature then a camera obscura or, better, Wollaston's camera lucida may be used. Other instruments are made for the construction of perspective drawings. It will often happen that the vanishing point of one direction which would be useless if the construction falls at a great distance off the paper, and various methods have been proposed of drawing lines through such a point. For some of these see Stanley's Descriptive Treatise on Mathematical Drawing Instruments. (O.H.)

PERSPIRATION (Lat. per, through, and spirare, to breathe), the excretion of sweat from the sweat-glands of the skin. Sweat is a clear colourless neutral or slightly alkaline fluid containing 2% of solids. Under pathological conditions, sugar and other substances are found. The secretion of sweat is constantly going on, the activity of the sweat-glands being under control of the central nervous system. The only function of sweat is the regulation of the heat discharge from the body. The chief morbid conditions of the sweat-glands are excessive sweating (Hyperidrosis) and foetid sweating (Brondrosis). Excessive sweating is a symptom observed in various diseases, such as tuberculosis and rheumatic fever, but it may exist apart from such conditions, and either be general, affecting the whole body, or confined to a part, such as the axillae, head, hands, feet, or, as in some rare instances, the one half of the body. Excessive perspiration may often be prevented by the cold bath, and by tonics, such as iron, quinine, strychnin, &c. Locally, the use of astringent lotions of vinegar or a weak solution of lead will also be of service. Foetid sweating most frequently affects the feet, specially in those who have much fatigue, and is apparently due to rapid decomposition in the perspiration which has saturated the stockings; these should be frequently changed and the feet bathed daily, dried carefully, and dusted with some antiseptic powder.

PERTAB (or PARTAN) SINGH, Sir, maharaja of Idar (1844- ), native Indian soldier and statesman, belonging to the Rahtor Rajputs of the Jodha class, was born in 1844, being the son of Maharaja Takht Singh, ruler of Marwar (or Jodhpur). In 1878 and again in 1879 he was chief minister of Jodhpur. In the following year he accompanied the British mission to Afghanistan, and on his return he carried out many judicial reforms and administered Jodhpur with remarkable success. He visited England to take part in the celebration of the 1857 Jubilee of Queen Victoria's reign. He served on the staffs of Sir William Lockhart and General Ells in the Tirah and Momand expeditions in 1897-98, was slightly wounded, was mentioned in despatches, and promoted to the rank of full colonel. He won the reputation of being one of the keenest sportsmen and the best riders ever in the region. When it was decided to send a force from India to China in 1900 to relieve the foreign embassies besieged in Peking, Sir Pertab Singh at once offered the services of the Jodhpur Lancers, and himself accompanied them. His father rendered good services to the British government in the Mutiny, and Pertab Singh always cherished the memory of the protection given to Jodhpur by the East India Company in 1818. His services to the empire in India were universally recognized. From Queen Victoria he received the honour of knighthood and the Bath and the Star of India; from King Edward VII. the distinction of "aide-de-camp"; and the university of Cambridge gave him the degree of LL.D. From his own state of Jodhpur he obtained the title of Maharaja-Dhiraj. In 1901 he succeeded to the rulership of the state of Idar.

PERTH, EARLS AND DUKES OF. The Scottish title of earl of Perth was bestowed upon James, 4th Lord Drummond (d. 1611) in 1605. His ancestor Sir John Drummond (d. 1519) had been created Lord Drummond in 1488. The 1st earl's great-nephew, James, 4th earl and 1st duke of Perth (1648-1716), was a son of James, the 3rd earl (c. 1615-1675). When John Maitland, duke of Lauderdale, was virtually the dictator of Scotland, Perth was among his opponents, and after Lauderdale's retirement in 1680 he was one of the committee of seven which managed Scottish affairs. He was made justice-general and extraordinary lord of session in 1682, and was lord chancellor of Scotland from 1684 to 1688. As a convert to Roman Catholicism after the death of Charles II., he stood high in the favour of James II. Perth, who is credited with the introduction of the thumbscrew, was very unpopular with the Scottish people, and during the Revolution of 1688 he was imprisoned at Stirling. Released from captivity in 1693 he joined James II. at St Germain, and was made duke of Perth, a titular dignity only after the exiled king's death in 1701. His son James (c. 1675-1720) was with James II. in Ireland, and led the cavalry at the battle of Sheriffmuir. He was attainted in 1715, but claimed the dukedom of Perth after his father's death. His son James (1713-1746), regarded by friends and dependants as the 3rd duke of Perth, fought for the Young Pretender at Prestonpans and Culloden. His brother and heir, John, the 4th duke (c. 1716-1747), also joined Charles Edward, and fought at Falkirk and Culloden. The titular dukedom became extinct when the sixth holder, Edward, another son of the 1st duke, died in 1760.

The earldom was then claimed by Edward's cousin, James Lundin (1707-1781), a grandson of the 1st titular duke of Melfort, who was a brother of the 1st duke of Perth and took the name of Drummond. His son James (1744-1800) secured the Drummond estates in 1783, and was created a British peer as Lord Perth and Baron Drummond in 1797. On his death without sons in July 1800 his barony became extinct, but the claim to the earldom of Perth was inherited by his kinsman, the 4th titular duke of Melfort, and his descendants (see below). The Drummond estates, however, passed to the baron's daughter Clementina (d. 1865), afterwards the wife of Peter Robert, 2oth Lord Willoughby de Eresby, and thence to her descendant the earl of Ancaster.

The 1st duke's brother, John (c. 1650-1715), earl of Melfort, was more fortunate than Charles II. about the same time as his brother; like him, too, he became a Roman Catholic in 1686. In 1684 he was made secretary of state for Scotland; in 1686 he was created earl of Melfort by James II., and during his reign he took a leading part in Scottish affairs. After the Revolution of 1688 his great influence with James II. and with Mary of Modena drew upon him the hatred both of the French and of the Irish. He was with James II. at St Germain, but lost his former ascendancy, and died in Paris on the 25th of January 1715. In 1694 he was made duke of Melfort, and all his titles were held under the singular condition that they should descend to the children of his second wife, Euphemia (d. 1743), daughter of Sir Thomas Wallace, in preference to his children by his first wife, Sophia Lundin, who were Protestants. In 1701 Melfort was recognized as a French peer, the duc de Melfort, by Louis XIV. In 1692 he had been attainted, but his titles were claimed by John (1632-1754), his eldest son by his second wife, who shared in the rising of 1715. In 1700 John's grandson, James Louis, 4th titular duke of Melfort, claimed the earldom of Perth. This claim was unsuccessful, but in 1753 George (1707-1792), nominally 6th duke of Melfort, obtained a reversal of the various attainers, and his own recognition as earl of Perth and Melfort. The succeeding earl was his kinsman, William Huntary Drummond, Viscount Stratellan (1781-).

PERTH, the capital of Western Australia, situated on the Swan River, 12 m. by rail from the sea at Fremantle, and about 1700 m. W.N.W. of Melbourne. It is the seat of both Anglican and Roman Catholic bishops, and has two cathedrals. The fashionable street is St George's Terrace; in it are situated the public library, the government 'boys' school, the stock exchange, the town-hall, the government offices and the parliament buildings. Between it and the broad reach of the river known as Perth Water lie the governor's residence and domain. The
PERTH, a city, and royal, municipal and police burgh, and county town of Perthshire, Scotland, 32 m. N. by W. of Edinburgh direct, and 472 m. by the North British railway, via the Forth Bridge and Kinross Junction. Pop. (1901), 33,556.

It is situated on the right bank of the Tay, between the meadows of the North Inch (98 acres) and those of the South Inch (72 acres), both laid out as public parks. The river is crossed by St John's Bridge of nine arches, completed in 1773 from the designs of John Smeaton and widened a century later; by Victoria Bridge, a modern structure connecting South Street with Dundee Road; and farther south (at the end of Tay Street) by a footway alongside of the viaduct belonging to the Caledonian railway. Of earlier bridges one, which crossed at High Street, was swept away by the flood of 1821, and another, constructed by General Wade in 1723-1733, was apparently the predecessor of Smeaton's bridge. On the left bank of the river lie the suburb of Bridgend and Kinnoull Hill (720 ft.). To the south are the wood-clad heights of Moncrieffe Hill (725 ft.), Magdaleness Hill (596 ft.), Kirkton Hill (540 ft.) and Craigie Wood (407 ft). In the river are Friarton or Moncrieffe Island and the Stanners.

Notwithstanding the importance of Perth in former times, almost the sole relic of the past is the church of St John the Baptist, a large Decorated cruciform building surmounted by a massive square central tower 125 ft. high. The original edifice is believed to have been erected in the time of Columbus, but the transept and nave of the existing structure date from the early part of the 13th century, the choir from the 15th. The church was restored in 1801, and is now divided into the East, Middle and West churches. The silver-gilt communion cup used in the Middle Church is said to have been presented by Queen Mary. In May 1559 John Knox preached in St John's his famous sermon in denunciation of idolatry. The Dominican or Blackfriars' monastery, founded by Alexander II. in 1231, occupied a site near the west end of St John's Bridge; in what is now King Street stood the Cuthbertian monastery, founded by James I. in 1415; the Franciscan or Greyfriars' monastery, founded in 1460 by Laurance, first Lord Oliphant, stood on the present Greyfriars' cemetery; the Carmelite or Whitefriars' monastery, founded in 1280, stood west of the town. The tombstone of James I. and his queen, who were buried in the Charterhouse, was afterwards removed to St John's East Church. During the period between the beginning of the 12th century and the assassination of James I. in 1437, many of the Scottish parliaments were held in Perth. The building in which they met stood off High Street and was only cleared away in 1818, its site being occupied by the Freemasons' Hall. The earl of Gowrie's palace, built in 1520, stood in spacious grounds near the river and was removed in 1805 to provide room for the county buildings. The castle of Perth stood on the north of High Street, not far from St John's. It was probably built about 860 and demolished about 1400. The Spey or Spy tower, the most important fortress on the city wall, guarded the south gate close to the river, but it was taken down early in the 19th century. The market cross, erected in High Street in 1669 to replace the older cross which Cromwell destroyed, was removed in 1765 as an obstruction. The huge fortress, 466 ft. square, which Cromwell erected in 1651 on the South Inch, close to the river and the Greyfriars' burying-ground, was demolished in 1863. The house of Catherine Glover, the "Fair Maid of Perth," still stands in Curfew Row. James VI.'s Hospital, founded in 1569, occupies the site of the Cuthbertian monastery, the original structure having been pulled down by Cromwell's orders. The pensioners now live out and the hospital has been converted into artisans' dwellings. Among modern public buildings the principal are St Ninian's Episcopal Cathedral, in the Early Middle Pointed style, an important example (completed 1890) of the work of William Butterfield (1814-1900); the municipal buildings (1891); the city-hall; the Marshall Memorial Hall (1823), housing the public library and the museum of the Perth Literary and Antiquarian Society; the Perthshire natural history museum; the Sandeman public library (1898), founded by a bequest of Professor Sandeman of Owen's College, Manchester. The general prison for Scotland, south of the South Inch, was originally erected in 1812 as a dépôt for French prisoners, but was remodelled as a convict prison in 1840 and afterwards enlarged. North-west of the city are the military barracks built in 1793-1794. Besides the regular elementary schools there are the Perth Academy (1807) with which was subsequently amalgamated the Burgh Grammar School, an institution supposed to date from the 12th century; Sharp's Institute (1860); the Stewart's free school, an industrial school for girls, and the Fecherney industrial school. The charitable institutions comprise the royal infirmary, in the Italian style, considerably enlarged since its foundation in 1836; the Murray royal lunatic asylum in Bridgend; the Hillside House in Kinnoull and the small-pox hospital.

From the south the city is entered by the North British railway and the Caledonian railway (which also runs west to St Fillans, east to Dundee and north-west to Aberdeen); and from the north by the Highland railway, the three systems utilizing a general station in the south-west of the town. During the season there is communication with Dundee and other river ports by steamer. The navigation of the stream is considerably obstructed by sandbanks, but vessels of 200 tons can unload at the quays, which, with the town and Friarton harbours, lie below the South Inch. The greatest tidal rise is 13 ft. The chief imports are Baltic timber, coal, salt and manure; and the exports, manufactured goods, grain, potatoes and slates. Perth has also been famous for its weaving, dyeing and bleaching, the bleach-fields being mostly situated outside of the city, in convenient proximity to the Tay and Almond. The other leading industries include manufactures of gauge-glasses, ink, muslins, India shawls, jute goods, woolens and winceys, floorcloth, and boots and shoes. There are iron foundries, breweries, distilleries, rope and sail works, coach-building yards, steam joinery works, and brick and tile works. The salmon fisheries of the Tay yield a substantial revenue. Perth is under the jurisdiction of a town council, with a lord provost and bailies, and returns one member to parliament.

History.—During the time that it was occupied by the Romans, a period estimated at 320 years, the city was called Victorina; but shortly after their withdrawal it seems to have borne the Celtic appellation of Aber-tha ("at the mouth of the Tay"). The transition to the latinized form Bertha and later to Perth (the Gaelic name being Peth) appears obvious. On the conversion of the original Pictish inhabitants and the dedication of the first church to St John the Baptist, the town
was designated St Johnstoun, and it continued to be known indifferently by this name and that of Perth down to the 17th century. Roman remains have often been found in excavations carried out within the existing boundaries, which suggests that the Roman settlement was at least twenty feet below the present surface. The obscurity of the early annals of the town is explained by the circumstance that Edward I. caused the records to be removed. Perth is stated to have been a burgh in 1166 and was made a royal burgh by William the Lion in 1210. During the Scottish wars of the Independence its fortifications were strengthened by Edward I. (1268). Robert Bruce several times ineffectually attempted to seize it, but in 1311 it succeeded in scaling the walls during a night attack. This was the fourth and most brilliant of the seven sieges which the city has sustained. Taken by Edward III. in 1335, it was recaptured in 1339. In 1396 the combat between the Clan Chattan and the Clan Quhaile, described in Scott's "Aair Mhòr of Perth", took place on the North Inch in presence of Robert III. and his queen, Annabella Drummond. The Blackfriars' monastery was the scene of the murder of James I. by Walter, earl of Atholl, in 1437. In consequence Perth lost its status as capital, in which it had succeeded to Scone, and the Parliament Courts were transferred to Edinburgh in 1482. Gowrie Palace was the scene of the mysterious "Gowrie" conspiracy against James VI. in 1600. The town was taken by Montrose in 1644, by Cromwell in 1651, and was occupied by Viscount Dundee in 1651. In 1715 the Old Pretender was proclaimed king at the Mercat Cross (Sept. 16), and the chevalier himself appeared in the city in the following January, only to leave it precipitately on the approach of the earl of Argyll. Prince Charles Edward spent a few days in Perth from the 3rd of September 1745. In both rebellions the magistrates took the side of the Crown and were supported by the townsfolk generally. The Jacobites, drawing their strength mainly from the city, occupied all the men and gentry with their retainers. Since then the city has devoted itself to the pursuits of trade and commerce. Perth was visited by plague in 1512, 1585-1587, 1608 and 1645; by cholera in 1832; and the floods of 1210, 1621, 1740, 1773, and 1814 were exceptionally severe. 

AUTHORITIES.—Maidment, The Chronicle of Perth from 1210 to 1699 (1831); Penney, Traditions of Perth (1836); Lawson, The Book of Perth (1847); Peacock, Perth, its Annals and Archives (1849); Samuel Cowen, The Ancient Capital of Scotland (1902).

PERTH AMBOY, a city and port of entry of Middlesex county, New Jersey, U.S.A., at the mouth of the Raritan river, on Raritan Bay and Staten Island Rapid Transit railways, and by boats to New York City. It is connected by a railway bridge (C.R.R. of N.J.) and by a foot and wagon bridge with South Amboy, on the south shore of the Raritan. Perth Amboy has a good harbour, shipyards and dry-docks. In the city still stands Franklin Palace (erected in 1764-1774), the home of William Franklin (1720-1813), a natural son of Benjamin Franklin and the last royal governor of New Jersey. In the vicinity is the Bartow House, in which William Dunlap (1766-1830), the art historian, made his first drawings. Other buildings of historic interest are the Parker Castle (c. 1729), a centre of Loyalist influence at the time of the War of Independence, and the Kearny Cottage, the home of "Madam Scribblerus," a half-sister of Captain James Lawrence. The city has various manufactures, the factory product in 1905 being valued at $4,600,000. Clay is obtained in the vicinity, and large shipments of coal are served by the docks. Perth Amboy was incorporated as a city in 1788. It was at first called Amboy after the original Indian name; in 1864 the proprietors named it Perth in honour of James, earl of Perth (1648-1716), one of their number, and a few years later the two names were combined. From 1686 until the end of the proprietary government in 1702 Perth Amboy was the capital of the province of East Jersey, and during the period of government the general assembly and supreme court of New Jersey met alternately here and at Burlington. Perth Amboy was incorporated as a city in 1718, and received a new charter in 1784, and another in 1844, the last being revised in 1870. The township of Perth Amboy was incorporated in 1693 and in 1844 was included in the city.

PERTHES, FRIEDRICH CHRISTOPH (1777-1843), German publisher, nephew of Johan Georg Perthes (q.v.), was born at Rudolstadt on the 21st of April 1777. At the age of fifteen he became an apprentice in the service of Adam Friedrich Böhme, a bookseller in Leipzig, with whom he remained for about six years. In Hamburg, where he settled in 1793 as an assistant to the bookseller B. G. Hoffmann, he started in 1796 a bookselling business of his own, and in 1798 he entered into partnership with his brother-in-law, Johann Heinrich Besser (1775-1826). By his marriage in 1797 with a daughter of the poet, Matthias Claudius, he was brought into intimate relation with a group of Protestant writers, who exercised a powerful influence on the growth of his religious opinions. This, however, did not prevent him from being on friendly terms with a number of eminent Roman Catholic authors. Perthes was an ardent patriot; and during the period of Napoleon's supremacy he distinguished himself by his steady resistance to French pretensions. His zeal for the national cause led him, in 1810-1811, to issue Das deutsche Museum, to which many of the foremost publicists in Germany contributed. For some time the French made it impossible for him to live in Hamburg; and when, in 1814, he returned to that city he found that his business had greatly diminished. In 1821, his wife having died, he left Hamburg, transferring his business there to his partner, and went to Gotha, where he established what ultimately became one of the first publishing houses in Germany. It was owing to his initiation that the Börsenverein der deutschen Buchhändler (Union of German Booksellers) in Leipzig was founded in 1825. When the foundation-stone of the fine building of the Union was laid in 1834, Perthes was made an honorary freeman of the city of Leipzig, and in 1840 the university of Kiel conferred upon him the degree of doctor of philosophy. Perthes died at Gotha on the 18th of May 1843. His Life was written by his son, Klemens Theodor Perthes (1809-1867), professor of law in the university of Bonn, and author of Das deutsche Staatslehen vor der Revolution (Hamburg and Gotha, 1845), and Das Herbgewesen der Handwerksge- sellen (Gotha, 1856, and again 1883), whose son Hermann Friedrich Perthes (1840-1883) was the founder of the Fridericianum at Davos Platz. The publishing business at Gotha was carried on by Perthes's younger son, Andreas, (1813-1890) and his grandson, Emil (1814- ), until 1889, when it was handed over to a company.

See also O. Adler, Friedrich and Karoline Perthes (Leipzig, 1900).

PERTHES, JOHAN GEORG JUSTUS (1740-1816), German publisher, was born at Rudolstadt on the 11th of September 1740. In 1785 he founded at Gotha the business which bears his name (Justus Perthes). In this he was joined in 1814 by his son Wilhelm (1793-1853), who had been in the establishment of Justus' nephew, Friedrich Christoph Perthes, at Hamburg. On the death of Justus at Gotha on the 2nd of May 1816, Wilhelm took entire control of the firm. He laid the foundation of the geographical branch of the business, for which it is chiefly famous, by publishing the Hand-Atlas (1817-1823) of Adolf Stieler (1775-1836). Wilhelm Perthes engaged the collaboration of the most eminent German geographers of the time, including Heinrich Berghaus, Christian Gottlieb Reichard (1758-1837), who was associated with Stieler in the compilation of the atlas, Karl Spruner (1803-1862) and Emil von Sydow (1782-1873). The business passed to his son Bernard Wilhelm Perthes (1821-1857), who was associated with August Petermann (under whose direction the well-known periodical Petermanns Mitteilungen was founded) and Bruno Hassenstein (1839-1902); and subsequently to his son Bernard (1857- ). In 1863 the firm first issued the Almanach de Gotha, a statistical, historical and genealogical annual (in French) of the various countries of the
PERTHSHIRE

world; and in 1866 the elaborate Geographisches Jahrbuch was produced under the editorship of Ernst Behm (1830–1884), on whose death it was continued under that of Professor Hermann Wagner.

PERTHSHIRE, an inland county of Scotland, bounded N. by the shires of Inverness and Aberdeen; E. by Forfarshire; S.E. by the Firth of Tay and the counties of Fife and Kinross; S. by the shires of Clackmannan and Stirling; S.W. by the counties of Stirling and Dumbarton; W. by Argyllshire and N.W. by Inverness-shire. It is the fourth largest county in Scotland, having an area of 1,505,774 acres, or 2493.4 sq. m., including the island of Mugdrum in the Firth of Tay. By far the greatest part of the county is mountainous. Including the hills on the confines of Inverness-shire and Argyllshire, there are at least fifty mountains exceeding 3000 ft. in height. Of these the most familiar are Ben Lawers (3984 ft.) near Loch Tay, Ben More (3843) east of Crieff, Ben Lui (3708) on the Argyllshire border, Schiehallion (3547) south of Loch Rannoch, Ben Vannoch (1125) west of Loch Vanoich (gathering or g986) on the head of Glen Almond. Of the immense number of hills of lesser altitude there may be mentioned four that have been popularized by the Lady of the Lake—Ben Ledi (2875) and Uam Var (2179) near Callander, and Ben Venue (2939) and Ben An (1750), guardians of the Trossachs. The Ochils divide Perthshire from the shires of Clackmannan, Kinross and Fife. The chief stream is the Tay, which rises on the Argyllshire frontier and discharges into the North Sea off Buddon Ness, after a course of 117 m., being thus the longest river in Scotland. Its head-waters are the Fillan and Dochart, and among its affluents are, on the right, the Braan, Almond and Earn and, on the left, the Lyon, Tummel, rising in Argyllshire and receiving the Garry on its left, and Isla. The Earn flows out of Loch Earn and enters the Firth of Tay 63 m. below Perth. The Firth, the principal natural boundary of the shire on the south, properly belongs to Kinross and Stirling. The river and its affluents, including the lower basins of the Tay, are called the Tay basin. Those of the Ochils, Aray, Earn, Vennachar and Earn, are bounded by the popularized name of the Lady of the Lake.

India—The mountainous territory is extremely wet, the rainfall for the year varying from 120 to 183 in. in Glenlyon at the head of Loch Ericht, to only 60 in. in Pitlochry, Perthshire. Winter and autumn are the rainiest seasons. The temperature is remarkably constant everywhere, averaging 47° F. for the year, January being the coldest month (36° F.) and July the hottest (53° F.). Only a little more than one-fifth of the total area is under cultivation, and of this nearly one-third is in permanent pasture, while in addition there are about 930,000 acres of hill pasturage. The arable land is chiefly in the drier regions of the county, and the deep loam and sandstone soils prevail in the lower undulating districts; clay and alluvial land occur in the Carse of Gowrie, the Carse of Stirling and the lower reach of Strathearn below and above Bridge of Earn. The best lands are the Carse lands and the Carlowrie and Loweside lands. The low-lying farms, the herds of the straths and mountain pastures being most usual on the West Highland and the Clyde. The uplands, however, are extensively under cultivation.

Geology.—The Highland portion of this county is built up of a great series of schists and metamorphosed rocks grouped as Dalradian or Eastern schists. The general direction of the strike of these rocks is W.S.W.—E.N.E. They are cut off from the Old Red Sandstone, which occupies most of the remainder of the county, by the great fault which traverses the county somewhat to the north of Aberfoyle and Crieff. But for some distance north and south of Crieff and Callander the two formations are indistinguishable, and unconformable one. In the neighbourhood of the fault line the Highland schists are less metamorphosed than they are farther north; about Comrie and Callander they consist of slates, greywackes and sandstones which are indistinguishable from the rocks of Argeni age in south Scotland. At Aberfoyle, Comrie and Dunkeld roofing slates are worked and massive limestones occur in Glen Tilt, Pitlochry, Callander, Blair Atholl, Loch Rannoch and other places. A gritty series comes on above the slates and is well seen capping the summit of Ben Vorlich. A great variety of schists form the bulk of the series; but granite masses appear in their midst as at Loch Rannoch, Loch Erich and Glen Tilt, and there are numerous acid and intermediate dikes which are themselves traversed by basaltic dikes. The Old Red Sandstone consists in the lower portion of the series of volcanic agglomerates and lava flows followed by conglomerates, sandstones and marls. The lowest beds are exposed along the crest of the Ochil Hills which lie the Sidlaw Hills are antecedent in structure, while the Ochils are the principal faulted part of the area. The rocks are folded into synclines; near the fault they become very steeply inclined and even inverted, and it is interesting also to note that the sediments become coarser as the fault is approached. The Old Red Sandstone beds are divided into the Carse of Gowrie and it extends beneath the marine platform of the Carse of Gowrie. The rocks are mainly sandstone beds, and terraces, let down between two parallel east and west faults but between the Bridge of Earn and the Carse of Gowrie, with the tract, the area is best unconformably upon the lower division. Small outliers of Carboniferous rocks (lower) occur on the north of the Ochils. The marks of ice action left by the Glacial epoch are abundant and stratigraphical intergrades; most of these are the same as those at the head of the Glengarry on borders of Loch Katrine; ice-scratched surfaces are found on the Sidlaw Hills, the Ochils, Kinnoull Hill and elsewhere; and erratic blocks of stone, such as the “Stones of Fingall” on the slope of Black Mountain near Callander, and the great erratic block at the head of a hill of Old Red Sandstone near Coiltante, are widely distributed. Old high level marine beaches form terraces far up several of the basins, and the Carse of Gowrie, as already indicated, is formed on the bed of a former sea. The coastal cliffs at the mouths of many of the gents which open on the south of the Ochils on the 100-ft. or 50-ft. beaches are often the site of villages.

Climate and Agriculture.—The mountainous territory is extremely wet, the rainfall for the year varying from 120 to 183 in. in Glenlyon at the head of Loch Ericht, to only 60 in. in Pitlochry, Perthshire. Winter and autumn are the rainiest seasons. The temperature is remarkably constant everywhere, averaging 47° F. for the year, January being the coldest month (36° F.) and July the hottest (53° F.). Only a little more than one-fifth of the total area is under cultivation, and of this nearly one-third is in permanent pasture, while in addition there are about 930,000 acres of hill pasturage. The arable land is chiefly in the drier regions of the county, and the deep loam and sandstone soils prevail in the lower undulating districts; clay and alluvial land occur in the Carse of Gowrie, the Carse of Stirling and the lower reach of Strathearn below and above Bridge of Earn. The best lands are the Carse lands and the Carlowrie and Loweside lands. The low-lying farms, the herds of the straths and mountain pastures being most usual on the West Highlands or Kyloes. Perthshire, next to Argyllshire, still carries the heaviest flakes in Scotland. Black-faced is the principal breed of cattle, and the county is of mixed breeds but requires as those at the head of the Glengarry on borders of Loch Katrine; ice-scratched surfaces are found on the Sidlaw Hills, the Ochils, Kinnoull Hill and elsewhere; and erratic blocks of stone, such as the “Stones of Fingall” on the slope of Black Mountain near Callander, and the great erratic block at the head of a hill of Old Red Sandstone near Coiltante, are widely distributed. Old high level marine beaches form terraces far up several of the basins, and the Carse of Gowrie, as already indicated, is formed on the bed of a former sea. The coastal cliffs at the mouths of many of the gents which open on the south of the Ochils on the 100-ft. or 50-ft. beaches are often the site of villages.

direction via Perth. At Crieff junction it sends off a branch to Crieff and at Perth branches to Dundee and Lochearnhead. The Stirling to Oban line of the same company crosses the shire from Dunblane to Tyndrum. The Highland railway runs northwards from Perth and has a branch at Ballingul to Aberfeldy. Branches of the North British railway reach Perth from Mawcarse in Kinross-shire and Ladybank in Fife; part of the branch from Buchlyvie on the Forth and Clyde line runs to Aberfoyle, and the West Highland line goes on from the extreme north of Perthshire into the eastern points. Coaches supplement the rail. In the tourist season steamers ply on Loch Tay and Loch Katrine, and there is a service on the Tay between Perth and Dundee.

**Population and Administration.—** In 1891 the population amounted to 122,185 and in 1901 to 123,283, or 40 persons to the sq. m. The rate of increase was the smallest of any Scottish county for the decade. In 1901 there were 78 persons speaking Gaelic only and 11,446 Gaelic and English. The chief towns are Perth (pop. 32,873), Crieff (5208), Blairgowrie (3787), Dunblane (2578), Auchterarder (2726), Coupar-Angus (2064), Rattray (2010). Among lesser centres may be mentioned Aberfeldy (1568), a favourite resort on the Tay, well known for the falls of the Birks of Aberfeldy; Abernethy (623), the seat of an early bishopric, retaining one of the three ancient round towers in Scotland; Alyth (1065); Callander (1458); Comrie (1188), a holiday resort on the Earn; Pitlochry (1541); and Stanley (1035), on the Tay. Of old the county was divided into hereditary jurisdictions, which were abolished in 1748, and in 1795 the county was divided into districts for administrative purposes, a system which obtained until 1880, when county and district councils were established. The sheriffdom is divided into an eastern and western district, the seat of the one being Perth and the other Dunblane. For parliamentary purposes the county is also divided into an eastern and a western division, and the city of Perth returns a member. The shire is under school-board jurisdiction and is divided into the extreme west of the shire. At several points centres may be found Stirling (2516), Perth (122,185), Crieff (11,446), Blairgowrie (7873), and Dunblane (11,446). The school population was 30,622 in 1901, 36,829 in 1906.

**History.—** In 83 Agricola explored the lands beyond the Forth and in the following year penetrated to the Grampians, defeating the Caledonians under Galgacus with great slaughter. The site of this battle is conjectured by William Forbes Skene to have been near Melikour, south of Blairgowrie, but other writers have referred it to Dalginross, near Comrie; to Ardorch (where there are the most perfect remains of a Roman encampment in the British Isles); and even as far north as Raedykes, near Stonehaven in Kincardineshire. The Romans did not pursue their victory, and the Picts were left undisturbed for a considerable period. At this time, according to Ptolemy, the territory now known as Perthshire was occupied by three tribes—the Danabonii, the Venicones and the Vacamagi. The Danabonii held Menteith, Strathearn and Fothir (the western part of modern Perth), and engaged with Aluna (Allan), just above Stirling, Lounds (Ardorch) and Victoria (believed by some authorities to be Lochore in Fife), and by others to be Perth city), their chief towns. The Venicones inhabited northern-western Fife and the adjoining tract of Perthshire, with Oreza (probably Abernethy) as their chief town and a station at Ardargie. The Vacamagi dwelt in the Highland region, with stations at Inch-tuthil (a peninsula in the Tay above Kinclaven) and Banatia (Buchanty on the Almond). The growing lawlessness of the southern Picts and their frequent raids in the more settled country in the south at last compelled the attention of the emperor Severus. He arrived in Britain in 208, but though he led a strong army to the shores of the Moray Firth, he was unable effectually to subdue the tribesmen. The road he constructed ran from Stirling to Ardorch (where there are notable remains) and thence by Stregath, near Muthill, where it branched north-westwards to Dalginross and Buchanty, and north-eastwards to Perth and so to the Grampians. When the Romans finally withdrew from Britain, the Picts established their capital first at Abernethy and then at Forvetont. Abernethy was the centre of the Celtic church after the conversion of the natives by Ninian, Palladius and other missionaries in the 5th and 6th centuries. On the burning of Forteviot by the Norsemen in the 8th century, the seat of Pictish government was removed to Scone. In the latter half of the 9th century Dunkeld—to which Kenneth Macalpine had brought some of the relics of Columba from Iona—became the scene of monastic activity, the abbott succeeding to the position of the abbot of Iona, and exercising great influence for nearly a hundred years. The Danes periodically harried the land, but a crushing defeat at Luncarty in 961 put an end to their inroads in this quarter. In 1034 Macbeth was defeated at Dunswinian by Siward, earl of Northumberland, who had invaded Scotland in the interest of his kinsman, Duncan's son, who, on the death of the usurper three years later, ascended the throne as Malcolm III., called Canmore. With Malcolm's accession the Celtic rule of the monarchy of Scone came to an end. Nevertheless, the Scottish sovereigns (excepting James II., James III. and Mary) continued to be crowned at Scone, which also retained the position of capital until the beginning of the 12th century, when it was displaced by Perth. From the time of Alexander I. (1107) therefore, the history of the shire is merged in that of the county-town, with the exception of such isolated incidents as the removal of the Coronation Stone from Scone to Westminster in 1206, the defeat of Robert Bruce at Methven in 1306, the battle of Dupplin in 1332, the victory of Dundee at Killicrankie in 1689 and the indecisive contest at Sheriffmuir in 1715. Among archaeological remains may be mentioned the hill-fort on Dunswinian; the ship-barrow of the Vikings at Rattray, weems (or earth-houses) in the parishes of Monzie, Alyth and Bendochy; the witch-stone near Carnbeddie, one of the numerous spots where Macbeth is alleged to have met the witches, but probably a sepulchral memorial of some forgotten battle; standing stones near Pitlochry, and an extraordinary assemblage of sculptured stones at Meigle.

**PERTINAX, PUBLIUS HELVIIUS** (A.D. 126–193), Roman emperor, the son of a charcoal-burner, was born at Alba Pompeia in Liguria. From being a teacher of grammar he rose through many important offices, both civil and military, to the consulate, which he held twice. Chosen, at an advanced age and against his will, on the 1st of January 193, to succeed Commodus, he was himself assassinated in a mutiny of the soldiers, on the 28th of March 193.

**PERTZ, GEORG HEINRICH** (1795–1876), German historian, was born at Hanover on the 28th of March 1795. From 1813 to 1818 he studied at Göttingen, chiefly under A. H. L. Heeren. His graduation thesis, published in 1819, on the history of the Merovingian mayors of the palace, attracted the attention of the prince of Baden, in whom he was engaged in 1820 to edit the Carolingian chroniclers for the newly-founded Historical Society of Germany. In search of materials for this purpose, Pertz made a prolonged tour through Germany and Italy, and on his return in 1823 he received at the instance of Steinh the principal charge of the publication of Monumenta germaniae historia, texts of all the more important historical writers on German affairs down to the year 1500, as well as of laws, imperial and regal archives, and other valuable documents, such as letters, falling within this period. Pertz made frequent journeys of exploration to the leading libraries and public record offices of Europe, publishing notes on the results of his explorations in the Archiv. der Gesellsch. f. deutsche Geschichtskunde (1824–1872). In 1823 he had been made secretary of the archives, and in 1827 principal keeper of the royal library at Hanover; from 1832 to 1837 he edited the Hannoversche Zeitung, and more than once sat as a representative in the Hanoverian second chamber. In 1844 he was called as chief librarian to Berlin, where he shortly afterwards was made a privy councillor and a member of the Academy of Sciences. He resigned all his appointments in
1874, and on the 7th of October 1876 died at Munich while attending the sittings of the historical commission.

The Monumenta began to appear in 1856, and at the date of his resignation 24 volumes folio (Scriptores, Leges, Diplomata) had appeared. This work for the first time made possible the existence of the modern school of scientific historians of medieval Germany. In connexion with the Monumenta Pertz also began the publication of a selection of sources in octavo form, the Scriptores rerum germanicarum in usum scholarum; among his other literary labours may be mentioned an edition of the Gesammt Werke of Leibnitz, and a life of Stein (Leben des Ministers Freiherrn von Stein (6 vols., 1849-1855); also, in an abridged form, Aus Steins Leben (2 vols., 1856).

A small river on the west coast of Colombia, where Pizarro landed), a republic of the Pacific coast of South America, extending in a general N.N.W.-S.S.E. direction from lat. 3° 21' S. to about 18° S., with a coast of 1,250 m. and a width of 300 to 400 m., exclusive of territories in dispute. Its area in 1896, including Tacna and Arica, and other disputed territories occupied by neighbouring states, was officially estimated at 1,752,422 sq. kilometers, or 676,638 sq. m.; exclusive of these territories, the area of Peru is variously estimated at 439,000 to 480,000 sq. m., the Gotha measurements being 417,000 sq. kilometers, or 439,014 sq. m.

With the exception of parts of the Ecuador, Brazil and Bolivia frontiers, all the boundary lines have been disputed and referred to arbitration—those with Colombia and Ecuador to the king of Spain, and that with Bolivia to the president of Argentina, on which a decision was rendered on the 6th of July 1909. There have been misunderstandings with Ecuador in regard to some small areas in the Chira valley, but it may be assumed that the line is fixed between Santa Rosa (3° 21' S.) on the Gulf of Guayaquil, and the Chinchipe river, a tributary of the Marañon. At the junction of the Cauchas with that river, that Ecuadorian line descends the Chinchipe to the Marañon, and the Peruvian ascends to a point where it is intersected by a line following the eastern Cordillera northward to the head-waters of the Cauquetá, or Japura, which forms the northern boundary down to the Brazilian frontier. This claim covers all eastern Ecuador and a large part of south-eastern Colombia. In 1901 there were encounters between small bodies of Peruvian and Ecuadorian troops on the disputed frontier. After arbitration by the king of Spain had been agreed upon, the question was considered by two Spanish commissions, and modifications favouring Peru were recommended. These became known prematurely, and in May 1910 war was threatened between Peru and Ecuador in spite of an offer of mediation by the United States, Brazil and Argentina under the Hague Convention.

From the Japura southward to the Amazon, in 4° 13' 21" S., 60° 35' W., and thence up the Javary, or Yavari, to its source in 7° 3' 4" S., 17° 46' 30" W., as determined by a mixed commission, the line was been definitely settled. From near the source of the Javary, or lat. 7° 3' 17" S., a line running eastward to the Madeira in lat. 6° 52' 15" S., which is half the distance between the mouth of the Mamoré and the mouth of the Madeira, divides the Spanish and Portuguese possessions in this part of South America, according to the provisions of the treaty of San Ildefonso of 1777. This line has been twice modified by treaties between Bolivia and Brazil, but without the consent of Peru, which claimed all the territory eastward to the Madeira between the above-mentioned line and the Beni-Madidi rivers, the line of demarcation following the Pablo-bamba, a small tributary of the Madidi, to its source, and thence in a straight line to the village of Conima, on Lake Titicaca. The dispute with Brazil relates to the territory acquired by that republic from Bolivia in 1867 and 1903, and was to be settled, according to an agreement.
of 1908, by direct negotiation if possible, or, failing this, by arbitration. The decision of the president of Argentina of the 9th of July 1909, in regard to the remainder of this extensive territory, was a compromise, and divided it into two nearly equal parts. The line adopted starts from Lake Suxes, the source of a small river of that name flowing into the north of Lake Titicaca, crosses the Cordillera by the Palomani to the Tambopata river, follows that stream to the mouth of the Lanza, thence crosses to the source of the Heath river, which forms the dividing line down to its junction with the Madre de Dios, descends that river to the mouth of the Turosanhas, thence in a straight line north-westly to the intersection of the Tahuamanu river by the 6th meridian, and thence north on that meridian to the Brazilian frontier. This decision at first gave offence to the Bolivians, but friendly overtures from Peru led to its acceptance by both parties with the understanding that modification might be made in locating the line wherever actual settlements had been made by either party on territory awarded to the other. With Chile the de jure line is that of the Camarones ravin which separated the old departments of Maquequega (including the provinces of Tacna and Arica) from the district of Iquique. The de facto line is that of the Sama river (usually dry), which opens on the coast a little south of Sama point, near 18° S., Chile retaining possession of the two above-mentioned provinces in violation of the treaty of Ancon, which she forced upon her defeated antagonist.

Physical Geography.—Peru is divided longitudinally into three well-defined regions, the coast, the sierra and the montaña. The coast, extending from the base of the Western or Maritime Cordillera to the position of the sandy desert crossed at intervals by rivers flowing through narrow, fertile valleys, is the region of the Andes, and is about 250 m. in width. It contains stunted chains of mountains, elevated plains and tabular range separated by rivers and ravines. The montaña is the region of tropical forests within the limits of the Amazon and skirts the eastern slopes of the Andes. The coast has been upraised from the ocean at no very distant geological epoch, and nearly as destitute of vegetation as the sands of the Sahara. It exhibits two main streams which cross the desert at intervals. Half of these have their origin in the summits of the Andes, and run with a dependent supply of water into the sea. The other, rising in the outer range, which does not reach the line between sea and desert, and receives less moisture, carry a volume of water to the sea during the rainy season, but for the rest of the year are nearly dry. The absence of rain here is ascribed to the action of the lofty uplands of the Andes, which intercept the influence of the cold Humboldt current sweeping northward along the west coast of the continent. The south-east trade-wind blows obliquely across the Atlantic Ocean until it reaches Brazil. By this time it is heavily laden with moisture which falls in the Sierra and La Plata. When the wind rises above the snow-capped Andes, the last particle of moisture is wrung from it by a very clear and dry wind on the Pacific slope. The west coast of the Andes is drained by lines or groups of palms, by fine old willows (Salix humboldtiana), fruit-gardens, and fields of cotton, Indian corn, sugar-cane and alfalfa. The vegetation is generally expanse of sugar-cane, in others cotton, whilst in others vineyards or grape-wines for wine or raisins. The woods on this coast are used for pasture, and horses and cattle enjoying the plentiful yellow pods.

The coast-region of Peru is divided into five sections, beginning northwards: (1) the Litoral region; (2) the Lambayeque and Trujillo section; (3) the Santa valleys; (4) the section from Lima to Nasca; (5) the region of Arequipa and the Pampas.

(1) The great desert region of Peru extends for nearly 200 m. from the Gulf of Guayaquil to the borders of the Morrocoy Valley, and is traversed by three rivers—the Tumbes, Chira and Flora, the two latter receiving their waters from the inner Cordillera and breaking through, on reaching the confines of South America east farthest to the westward until it reaches the Rio Blanco and Pariña, and then turns southward to the Bay of Paita. The climate of Flora is modified by the lower latitude, and also by the vicinity of the lofty coasts of Peru. Goura are much less frequent than in the coast-region farther south, while rain sometimes falls. At intervals of three or four years there are occasional heavy showers of rain from February to April. (2) The succession of the valleys of the Morrocoy, the Chiclayo, and Lambayeque, the Santa, the Moche, the Chicama, Moche, Viru and Chao. With the intervening deserts this section extends over 200 m. All these valleys, except Morrocoy and Chiclayo, have their sources far in the recesses of the mountains, and which furnish the supply of fresh water in the season when irrigation is needed. (3) The third section, also extending for 200 m., contains the valleys of Santa, Moche, Chicama, Huaura, Lambayeque, Pariví, Supé and Huarau, the San Pedro and the Huaura. The river Santa, which rises in the north-west, and below the sea, and has a length of 180 m., is remarkable for its long course between the outer and central ranges of the Andes, in a course known as the "Carcaj de Huyau," 100 m. in length. It then breaks through the mountains, and flows along a course of 35 m. over the coast-belt, and after fertilizing a rich valley, the Santa and Nepeña valleys are separated by a desert. The Nepeña valley rises on the slope of an outer range called the Cordillera Negra, and are consequently dry during the great part of the year. Wells and springs are not abundant in the fertile valleys of the province.
through the outer range from their distant sources in the snowly Cordillera, and have a perennial supply of water. There are 9 leagues of desert between the Nepeña and Casma, 16 between the Casma and Huarmey, and 18 between the Huarmey and Fortaleza. The latter desert, much of which is loose sand, is called the Parangue de Mata Cavallinos, from the number of exhausted animals which die there. Between the Supé and Pativilca is the desert called the Pampa del Medio Mundo. (4) The next coast-section extends for over 500 m. to the Decauville, where the valley is narrower and more regular. The valley of Carabayllo and Rinche contain a large amount of the fertile plain of Supe, and the important valley of Arequipa, though on its western slope, is 7,000 ft. above the sea and 90 m. from the coast. Most of the rivers here have their sources in the central range, and are of the character of those of Peru, being, for the most part, from 6 to 10 m. wide. (5) The Arequipa and Tacna section extends over 350 m. and comprises the valleys of Acaí, Atequipa, Atico, Ocoña, Majes or Camana, Quilla, with the interior valley of Arequipa, Tambo, Ilo or Moquegua, Ite or Locumba, Santa or Tacaí, and Arenal or Arica, the upper part of the western Cordillera recedes, and the important valley of Arequipa, though on its western slope, is 7,000 ft. above the sea, and 90 m. from the coast, on, 8° 46' 30" S. Corocibado is in 8° 57' S. La Viuda is off the port of Casma, in 9° 23' 30" S.; and Tortuga is 2 m. distant to the north. Santa Islet lies off the bay of Cosca, in 9° 53' 43" S. and 5° 24' 43" W. On the rocks and spurs of the town of Tres Cruces, in 12° 4' 38" S. and 74° 51' 34" W., is a solitary, 4 ft. long by 1 m. broad, forming the Bay of Callao; its highest point is 1,950 ft. Off its south-east end lies a small but lofty islet called Fronton, and to the south-west are the Islets of Huaylas, and off the island of Isla de Ilo, 6° 21' 42" S. and 74° 20' 18" W., is a lofty morro of Arica. All these rocks and islets are barren and uninhabitable.

The more common sea-birds are the Sula variegata or guano-bird, a large gull called the Larus modestus, the Pelecanus or Diving Pelican, the Eudocimus, or Guano-duck, and the Phalacrocorax or Black-crested Pigeon, with many smaller species of ducks, sea-angels, and other sea-birds. The hills and plains in this region are diversified with low, sandy morrmos, or luxuriant wilderness, and sierra, or inhabitable mountain slopes and valleys. This great mountain-system, running south-east to north-west, consists of three chains or groups of two chains, which run parallel and near each other on the western side, are of identical origin, and have been separated by the action of water during many centuries. On these chains are the volcanoes and many thermal springs. The narrow space between them is for the most part, but not always, a coherent range of hills called the province of Cerro Pasco, and the sources of the coast-rivers. The great eastern chain, rising from

the basin of the Amazon and forming the inner wall of the system, is of distinct origin. These three chains are called the Western or Cordillera Occidental, the Central Cordillera, and the Andes. Paz Soldan and other Peruvian geographers give the name of Andes,所以自然导出}

The Maritime Cordillera of Peru has no connexion with the coast ranges of Chile, but is a continuation of the Cordillera Occidental of Chile, which under various local names forms the eastern margin of the Cordillera Occidental, in the north-west of Peru. On the coast of Peru there is a group of volcanic peaks, clustering round those of Ulimas and Huaynaputina. A great eruption of Ulimasputina began on the 15th of February 1699 and continued until the 28th. But the great volcanic area mass is that of Misti, and the volcanic mountain rises over the city of Arequipa in a perfect cone to a height of over 20,013 ft. and near its base are the hot sulphur and iron springs of Yura. The peak of Sarasara, in Farinacochas (Acyachos) is 19,500 ft. above the sea,and in the mountains above Lima the passes attain a height of more than 15,000 ft. In latitude 10° S. the maritime chain separates into two branches, which run parallel to each other for 100 m., enclosing the remarkable ravine of Cuzco and Huamanga, the upper end of which, at 10° 20' S., is the Cordillera Nevada and the western as the Cordillera Negra. On the right the peak of Huamanga reaches a height of 22,951 ft. The Huanayay peak, above Carhuaza, rises to 21,088 ft.; the Hualcan or Huancan peak, above Chumayo, is 20,175 ft.; and the most northern of the peaks in this part of the chain reach a height of 19,000 ft. During the rainy season, from October to May, the sky is generally clear at dawn, and the magnificent snowy peaks are clearly seen. The last quarter of the year is the most sombre and disastrous. The Peruvian line of perpetual snow is at 16,400 ft.; but on the Cordillera Nevada, above the Cuzco de Huaylas, it sinks to 15,400 ft. This greater cold is caused by the intervention of the Cordillera Negra, which intercepts the warmth from the coast. As this lower line of perpetual snow reaches a height of 14,000 ft., about 40 m. west, while more than twenty coast streams rise on its slopes and force their way through the maritime chain. The Central Cordillera consists mainly of crystalline and volcanic rocks, on each side of which the mountainous area is clear, and the interior as though traversed vertically. In 14° 30' S. the central chain is connected with the Eastern Andes by the transverse mountain-knot of Vilcañota, the peak of that name being 17,651 ft. above the sea. The great inland pass of Huaylas—the eastern or main branch being known as the Cordillera Negra—begins to subside, while the Maritime Cordillera continues as one chain and beyond the frontier of Ecuador.

The Central Cordillera is the true water-parting of the system. These Andes are from 15° 30' to 16° 45' S., from which point they run parallel with the Maritime Cordillera until, at Cerro Pasco, another transverse knot connects it with the Andes in 10° 30' S. lat. It then continues northward, separating the basins of the Marathon and the Huaylas, and the central portion of Peru it is at length broken through by the Marathon flowing eastward.

The Eastern Andes is a magnificent range in the southern part of Peru, of Silurian formation, with talcose and clay shales, many quartz veins and eruptions of granitic rocks. Mr Forbes says that the thicks of Ilas, A (21,096 ft.) and Ilimani (21,014 ft.) in Bolivia are Silurian and fossiliferous to their summits. The eastern range is cut through by six rivers in Peru, namely, the Marathon and Huallaga, the Perene, Mantaro, Apurimac, Vilcamayu and Pauarcaranto, the last three being the most important. Most of the Eastern Andes in south Peru has a high plateau to the west and the vast plains of the Amazonian basin to the east. The whole range is highly arauciferous, and the thickness of the strata is not less than 10,000 ft. near the base of the range and a perpendicular crest at the very edge of the formation near Lake Titicaca, and in this respect it differs essentially from the Maritime Cordillera. To the eastward numerous spurs extend for varying distances into the great plain of Bolivia.

The Andes lose their majestic height to the northward; and beyond Cerro Pasco the eastern chain sinks into a lower range between the Huallaga and Uayacali. But throughout the length of Peru the three ranges of Andes are well marked. The Cerro Pasco extends from the Knot of Cerro Pasco to Ayacucho, about 200 m., including the Lake of Chinchay-cocha and the basin of the river Xauma. The third or Cuzco section extends to 250 m. to the Knot of Vilcañota with the basins of the Marathon and the Huaylas, and its height is 550 m. long by 100 broad. The second extends from the Knot of

Sections of Sierra.

The very best description of the sierra of Peru may be divided into four sections, each embracing portions of all three ranges. The first, from the north, comprises the upper basins of the Marathon and the Huallaga, and is 550 m. long by 100 broad. The second extends from the Knot of Cerro Pasco to Ayacucho, about 200 m., including the Lake of Chinchay-cocha and the basin of the river Xauma. The third or Cuzco section extends to 250 m. to the Knot of Vilcañota with the basins of the Marathon and the Huaylas, and its height is 550 m. long by 100 broad. The fourth is the basin of Lake Titicaca.
Lake Junin, or Chinchay-cocha, in the second section, is 36 m. long by 7 m. broad, and 13,232 ft. above the sea. Its marshy banks are overgrown with reeds and inhabited by numerous waterfowl. From this lake the river Xaua flows southwards through the hilly eastern slope of the Andes to the Pongo de Manco Capac, and thence, after a journey of 87 miles, to the Titicaca (see Bolivian), in the fourth or southern section, is divided between Peru and Bolivia. It receives a number of streams from the ranges shutting in the upper end of the valley; the Lake Titicaca is formed on the summit of an ancient volcano, Añangaro, both coming from the Knot of Vilcachota to the north. The Sources, which has its source in Lake Suches, falls into Lake Titicaca on the north-west side, as well as the Ylla and Ylave. The principal islands are Titicaca and Cusi (at the south end of the peninsula of Copacabana), Campanaria (9 m. from the east shore), Soto and Estesves. There are two other lakes in the Collao, as the elevated region round Titicaca is called. Lake Arape, a few miles north of the Titicaca, is the highest lake of the Andes, 13,232 ft. above sea level, and the Huallaga through that of Chasuta, enters the forest and unite after separate courses of about 600 and 400 m., the united flood then flowing eastward to the enter the slopes of the Cordilleras, and will open on the Huallaga river with a course of 600 m. The country between the Huallaga and the Ucayali, traversed by the Eastern Cordillera, is called the Pampa del Sacramento, and is characterized by extensive grassy plains. The southern limit of the montaña is watered by streams flowing from the eastern Andes, which go to form the river Madre de Dios and Amarumayu, the principal branch of the river Beni, which falls into the Madeira. The region of the Peruvian montaña, which is 800 m. long from the Marañón to the Bolivian frontier, is naturally divided into two sections, the sub-tropical forests in the ravines and the high montaña of the upper Andes. The Peruvian montaña forests in the Amazonian plain. The sub-tropical section is important from the value of its products and interesting from the grandeur and beauty of its scenery. Long spurs run off from the Andes, on the slopes of which grow the wild cucumber, C. Calisaya, is found in the forests of Carayaya in south Peru and in those of Bolivia. The species between Carayaya and the headwaters of the Huallaga yield very little of the febrifuge alkaloid, copaiba, a substance which is rich in cinchonine, an alkaloid efficacious as a febrifuge, though inferior to quinine. With the cinchona trees grow many kinds of melastomaceae, especially trees and shrubs, and numerous kinds of palms.

The other products of these warm valleys are excellent coffee, cocoa, sugar, tropical fruit, and all kinds of gold in abundance. In the broadened valleys farther east there are timber kinds of many trees, incense gums, a great wealth of the rubber trees of the Hevea genus, numerous varieties of beautiful palms, sarsaparilla, vanilla, ipaccharis, vast quantities of plants in abundance and varied fauna is the same as that of the Brazilian forests.

Geology. The Eastern Cordillera, which, however, is but little known, appears to consist, as in Bolivia, chiefly of Palaeozoic rocks; the rock formations are in general Foliated, although interspersed with recent volcanic lavas and ash; and the lower hills near the coast are composed of granite, syenite and other crystalline rocks, sometimes accompanied by limestones and sandstones, which are probably of the same age, and often covered by marine tertiary deposits. The broadened valleys and plains of the country correspond broadly with the geological classification.

The constitution of the Mesozoic band varies. Above Lima the western chain of the Andes is composed of pyroclitic and massive limestones, while the longitudinal valley of the Orinoco is hollowed in carbonaceous sandstones. From the analogy of the neighboring countries it is possible that some of the tuffs may be Jurassic, but the other deposits probably belong to the most part to the tertiary period. They are a deposit of volcanic ash, which from Gauf fossils. Like the similar sandstone in Bolivia, it includes seams of coal and is frequently impregnated with cinnabar. It is in this sandstone that the rich mercury mines of Huancavelica are found.

Farther north, in the department of Ancash, the Mesozoic belt is composed chiefly of sandstones and shales, and the limestones which form so prominent a feature above Lima seem to have disappeared. There are also found here coal seams, and others bear the name of diorite, and it is near these dikes that silver ores are chiefly found.

found. In the Cordillera Nevada the Mesozoic rocks which form the chain are often covered by masses of modern volcanic rock. Similar rocks are also found in the Cordillera Negra, but the volcanic centres appear to have been in the Sierra Nevada.

**Population.**—The first trustworthy enumeration of the people of Peru was made in 1793, when there were 617,700 Indians, 241,225 mestizos (Indian and white inter-mixture), 136,311 Spaniards, 40,337 negro slaves and 41,404 mulattoes, making a total of 1,076,977, exclusive of the wild Indians of the montaña. Viceroy Toledo’s enumeration of the Indians in 1575 gave them a total of 8,000,000, the greater part of whom had been sacrificed by Spanish cruelty. Others had withdrawn into the mountains and forests, and in the native villages under Spanish administration the birth rate had dropped to a small part of what it had been because the great bulk of the male population had been segregated in the mines and on the estates of the conquerors. This tells a story of depopulation under Spanish rule, to which the abandoned terraces (andenes) on the mountain sides, often highly cultivated, bear testimony. Several diverse totals have been published as the result of the census taken in 1876, which is considered imperfect. One estimate places the total at 2,860,881, comprising about 59% Indians, 17-6% Indians, 26-8% whites and 7-9% Asians, chiefly Chinese, and 24-8% mixed races. In 1896 estimates were made under official auspices (see A. Garland, *Peru in 1906*, Lima, 1907), which gave the population as 3,547,829, including Taçna (5000). It is believed, however, that this and other larger estimates are excessive. There is no considerable immigration.

The population of Peru is mixed, including whites, Indians, Africans, Asiatics, and their mixtures and sub-mixtures. The dominant race is of Spanish origin, to a considerable extent mixed with Indian blood. The Indians are in great part descendants of the various tribes organized under the rule of the Incas at the time of the Spanish conquest. There are two distinct general types—the coast tribes occupying the fertile river valleys, who are employed on the plantations, in domestic service in the cities, or in small industries of their own, no longer numerous; and the sierra tribes, who are agriculturists, miners, stock-breeder and packers, still comparatively numerous. In addition to these are the tribes of wild Indians of the montaña region, or eastern forests, who were never under Inca rule and are still practically independent. Their number is estimated at 50,000 to 300,000, divided into 112 tribes, and differing widely in habits, customs and material condition. Some live in settled communities and roughly cultivate the soil. Others are hunters and fishermen and are nomadic in habit. Others are intractable forest tribes, having no relations with the whites. The sierra or upland Indians, the most numerous and strongest type, belong largely to the Quichua and Aymará families, the former inhabiting the regions northward of Cuzco, and the latter occupying the Titicaca basin and the sierras of Bolivia. These Indians are generally described as Cholos, a name sometimes mistakenly applied to the mestizos, while the tribes of the eastern forests are called Chunchos, barbaros, or simply Indians. The Cholos may be roughly estimated at about 1,800,000 and form by far the larger part of the sierra population. Practically all the industries and occupations of this extensive region depend upon them for labourers and servants.

The mestizos are of mixed Spanish and Indian blood. There are two general classes—the costeños or those of the coast, and the serranos or those of the sierras. The mestizos of the coast are usually traders, artisans, overseas, petty officers and clerks, and small politicians. In the sierras they have the same general occupations, but there are no social bars to their advancement, and they become lawyers, physicians, priests, merchants, officials and capitalists. The African and Asiatic elements furnish only about 2% of each of the population. The Africans were introduced as slaves soon after the conquest, because the coast Indians were physically incapable of performing the work required of them on the sugar estates. All the heavy labour in the coast provinces was performed by them down to 1855, when African slavery was abolished. They have since preferred to live in the towns, although many continue on the plantations. The first Chinese coolies were introduced in 1849 to supply labourers on the sugar estates, which had begun to feel the effects of the suppression of the African slave traffic. At first the coolies were treated with cruelty. The scandals that resulted led to investigations and severe restrictions, and their employment now has become a matter of voluntary contract, usually for two years, in which fair dealing and good treatment are the rule. Many Chinese are also settled in the coast cities. Commercial relations have also been opened with Japan, and a small Japanese colony has been added to the population. The Spanish and African cross is to be seen in the mulattoes, quadroons and octoroons that inhabit the warm coast cities. Other race mixtures consist of the zambo (the African-Indian cross), an Asiatic graft upon these various crosses, and an extremely confusing intermixture of the various crosses, for which the Spanish races have descriptive appellations. The foreign population is chiefly concentrated in Lima and Callao, though mining and other industries have drawn small contingents to other places.

**Education.**— Universities and colleges were founded in Peru soon after the conquest, and Lima, Cuzco, Arequipa and Chuquisaca (now the Bolivian town of Sucre) became centres of considerable intellectual activity. Something was done for the education of the sons of the native inhabitants, but the schools were closed in 1810. The university of San Marcos at Lima is the oldest collegiate institution in the New World, originating in a grant from Charles V., in 1551 to the Dominicans for the establishment of a college in their monastery at Lima. Its present form was given it in 1574, as a university, and two years after its first secular rector had been chosen. The college of San Carlos was founded in 1770, and the school of medicine in 1792. At Cuzco the university of San Antonio Abad was established in 1608, and that of San Carlos, in 1805, closed in 1820, and in 1816. The instruction given in these institutions was of the religious-scholastic character of that time, and was wholly under the supervision of the Church. Independence opened the way for a considerable amount of intellectual enlightenment, especially for the upper classes. As organized under the law of the 5th of December 1865, primary instruction is free and nominally obligatory, and is under the control of the national government. The primary school is divided into a lower grade of three years, and a higher course of three years, in a school called the scholastic centre, in which learning a trade is included. There were 1908 elementary schools and 862 scholastic centres in 1906.

There are, besides these, a large number of private schools, which in 1906 carried about 22,000 pupils on their rolls, or three times the number in the public schools. To provide teachers six normal schools have been established, two of which (one for males and one for females) are in Lima. In addition there are 23 national colleges for boys in the various departmental capitals, and three similar colleges for girls, in Ayacucho, Cuzco and Trujillo. In these the majority of pupils were under the direction of Belgian and German instructors. The principal object of this grant is to stop what are called the croppers and there are at least two special schools that belong to the same category. For higher instruction there are four universities: the Universidad Mayor de San Marcos at Lima, and three provincial institutions at Arequipa, Cuzco and Trujillo. All these have faculties of letters and law, and San Marcos has in addition faculties of theology, medicine, mathematics and science, philosophy and administrative and political economy. The professional schools include a school of civil and mining engineering (created in 1829, as a part of the military school at Chorrillos under the direction of French instructors), a naval school at Callao, nine episcopal seminaries (one for each diocese), a national agricultural school in the vicinity of Lima (created 1902), and a few commercial and technical schools throughout the country. The education and training of youthful delinquents is regarded as the responsibility of the national government. The preparation of a young man for a profession is very much higher than in the United States.

**Science and Literature.**—Towards the end of the 18th century scientific studies began to receive attention in Peru. M. Godin, a pupil of the French geographer Baleato, was at about the same time in the court of the meridian near Quito, became professor of mathematics at San Marcos in 1759; and the botanical expeditions sent out from Spain gave further zest to scientific research. Dr Gabriel Moreno (d. 1800), a pupil of the French geographer Unanue, at Huamantanga, contributed to the Jesuit journal *Annales de Perou* under the direction of Dr Jussieu, and became an eminent botanist. Don Hipólito Unanue, born at Arica in 1755, wrote an important work on the climate of Lima and contributed to the *Mercurio peruano*. This periodical was started in 1793 at Lima, by a society called "amantes del pais," and it was completed in eleven volumes. It contains many valuable articles on history, topography, botany, mining, commerce and statistics. An almanac and guide for Peru was begun by the learned geographer Dr Cosme Bueno, and continued by Dr Unanue, who brought out his guides at Lima from 1793 to 1798. In 1794 a naval school was founded at Lima, with Andres Baleato as instructor and Pedro Alvarez as teacher of the use of instruments. Baleato also constructed a map of Peru.
A list of Peruvian authors in viceregal times occupies a long chapter in the life of St. Toribio by Montalvo; and the bibliographical labours of the Peruvian Leon Pinelo are still invaluable to Spanish students. The most prolific author of colonial times was Dr. Pedro de la Barrera, who, according to Pinelo, wrote more than sixty works, including an epic poem entitled *Lima fundada*.

The topographical labours of Cosme Bueno and Unanue were ably continued at Lima by Admiral Don Eduardo Carrasco, who compiled the *Geografía de Lima* (1821-1828), but the greatest work among Peruvian geographers is Dr Don Mariano Felipe Saltz Soldamano, the historian of the Jesuits in Peru, and whose merit, among good local annalists may be mentioned Juan Giliberto Valdivia, who has written a history of Arequipa, and Pio Bengno Mesa, the author of the *Annals of Cuzco*.

The principal writers on constitutional and legal subjects are Dr. Jose Santisteban, who has published volumes on civil and criminal law; Luis Felipe Villarán (subsequently rector of the university at Lima), author of a work on constitutional right; Dr. Francisco Guerreiro, who has written a work on commerce; and Dr. Constantino de la Hoz, author of a work on Peruvian legislation, in two volumes; Dr. Francisco Xavier Mariategui, one of the fathers of Peruvian independence; and Dr. Francisco de Paula Vigil (1792-1875), orator and statesman as well as author, whose work, *Defensa de los gobierneos* (1841), is a noble and enlightened statement of the case for civil governments against the pretensions of the court of Rome. Manuel A. Fuentes, an able statistician and the author of the *Estadísticas de Lima*, has also written a manual of parliamentary procedure. Perhaps the most original and interesting work of modern times is that of the Italian savant Antonio Raimondi (1825-1890), who spent the greater part of his life in studying the topography and natural resources of the country. Only four volumes of his work, the last of which was published at the time of his death, but he left a large mass of papers and manuscripts which the government has put in the hands of the Geographical Society of Lima for publication.

His great work is entitled *El Peru: estudios minerales, &c.* (3 vols., Lima, 1890-1892), a presentation volume of the department of Ancash. Peruvian literature since the independence has also attained high merit in the walks of poetry and romance. The Guayaquil author, Olmedo, who wrote the famous ode on the victory of Jujuy, has left in his five volumes of poetry, which are names well known wherever the Spanish language is spoken. Both died between 1860 and 1870. The comedies of Segura on the customs of Lima society, entitled *Un Paseo a Amaneces* and *La Sota de la Vida* (1877), engrave a most interesting picture of the social life of Peru, especially in Lima and in the sees of the various dioceses. Monasteries and nunneries are numerous, dating back to the 16th and 17th centuries, but their influence is now less potent than in those days and the monastic life is not the same as formerly. They are now devoted to educational work especially for girls, which is an obstacle to the successful development of a public school system in the country.

Políticos Divididos.—The empire of the Incas was divided into four main divisions, Chinchay-suyu to the north of Cuzco, Anti-suyu to the east, Colla-suyu to the south and Cunti-suyu to the west. The whole empire was being called Tihuanant-suyu, or the four governments. Each was ruled by a viceroy, under whom were the "hauarana-camayoces," or officers ruling over thousands, and inferior officers, in regular order, over 500, 100, and 50 men. All disorders and irregularities were checked by the periodic visits of the *lucyriko's* or inspectors. The Spanish conquest destroyed this complicated system. In 1569 the governor, Lope Garcia de Castro, divided Peru into corregimientos under officers named corregidores, of whom there were 77, each in direct communication with the government at Lima. An important administrative reform was made in 1784, when Peru was divided into 7 intendencias, each under an officer called an intendente. These intendencias included about 6 of the old corregimientos, which were called partidos, under officers named subdelegados. Thus the number of officers reporting direct to Lima was reduced from 77 to 7, a great improvement. The republic adopted the same system, calling the intendencias by the name of the Chosen Indian, but giving the intendencia, or chief intendente, the title of governor, while dividing it under a sub-prefect. Peru is divided into 18 departments, 2 ltoral provinces, and what is called the constitutional province of Callao. This is exclusive of Tacna and its 3 provinces. The departments, which contain 98 provinces, with their areas, capitals and estimated populations of 1906, are as follows: the

Apart from the departmental capitals there are several towns of size and importance. The so-called coast towns are commonly at some distance from the seashore, and their shipping ports are little more than a straggling collection of wretched habitations in the vicinity of the landing-stage and its offices and warehouses. Callao (q.v.) is a noteworthy exception, and Paita and Piura are something more than the average coast village. Near Lima, on the south, there are three bathing resorts, Chorrillos, Marina, and Barranco, which have handsome residences and large populations in the bathing season. North of Lima is the port and bathing resort of Ancon, in an extremely arid locality but having a fine beach, a healthy climate and a considerable population in the season. The towns of the coast region are usually built on the general plan, the streets crossing each other at right angles and enclosing squares, or quadrangles. In the sierra there is the same regular plan wherever the site is level enough. High-pitched red tiled roofs take the place of the flat roofs of the coast. The upper storey often recedes, leaving wide corridors under the overhanging eaves, and in the "plazas" there are frequently covered arcades. In addition to the capitals of the departments, Tarma (about 4000) and Xauxa, or Jauja (about 3000), are important towns of this region. In the montaña there are no towns of importance other than the capitals of the departments and the small river ports.

**Communications.**—The problem of easy and cheap transportation between the coast and the interior has been a vital one for Peru, for it determines the economic development of some of the richest parts of the republic. The arid character of the coastal zone, with an average width of about 80 m., permits cultivation of the soil only where water for irrigation is available. Only in the sierra and montaña regions is it possible to maintain a large population and develop the industries upon which their success as a nation depends. During colonial times and down to the middle of the 19th century pack animals were the only means of transportation across the desertlike montaña and over the rugged mountain trails. Railway construction in Peru began in 1848 with a short line from Callao to Lima, but the building of railway lines across the desert to the inland towns of the fertile river valleys and the Andean forests did not begin until two years later. These roads are of much to the productive resources of the country, but their extension to the sierra districts was still a vital necessity. Under the administration (1868-1872) of President José Balta the construction of two transandean and several coastal zone railways was begun, but their completion became impossible for want of funds. Balta's plans covered 1281 m. of state railways and 749 m. of private lines, the estimated cost to be about 347,900,000—a sum far beyond the resources of the republic. The two transandean lines were the famous Oroya railway, running from Callao to Oroya (1893), which crosses the Western Cordillera at an elevation of 15,645 ft., and later on to Cerro de Pasco (1904), the Goñiquirquisiga coal mines (1904) and Hauri (1906); and the southern line from Mollendo to Lake Titicaca, which reached Arequipa in 1869, Puno in 1871 and Checaucap (Cuzco branch) in 1906. Surveys were completed in 1896 by the extension of the Oroya line to Puno, and on a project for a line from Callao to the Pacific coast at first considered. The most important of connecting railways for the republic is that of its river system, comprising, as it does, the navigable channels of the Marañon, or upper Amazon, and its tributaries. It is officially estimated that this system comprises no less than 20,400 m. of connected riverways navigable at high water for all descriptions of boats, with a maximum rise in the upper waters of 5800 m. at low water. The rivers forming this system are the Marañon from Puerto Limon to Tabatinga on the Brazilian frontier (484 m.), the Purus and Larioa, and the Piura and Madre de Dios, which are pro forma only, as they are wholly under Brazilian jurisdiction. Practically the whole of the region through which these rivers run—the coast, the field, and the sierra—is under Spanish administration, with a few settlements of whites on the river courses. Its chief port is Iquitos, on the Marañon, 335 m. above the Brazilian frontier and 2563 m. from the mouth of the Amazon. It is visited by occasional steamers and supplies the country to the south from the seashore, and for winter months with goods from Brazil. The port of Callao is important for commerce and industry, and occasional steamers are sent to them with supplies and to bring away rubber and other forest products. Of the rivers farther south, which discharge into the Amazon through the Madeira, the Madeira, or Madre de Dios alone offers an extended navigable channel, together with the Apurimac, lower Ucayali, and the lower Heath and Chandlees. Of a widely different character is the navigation of Lake Titicaca, where steamers ply regularly between Puno and Quairu, the latter on the south-east shore in railway connexion with La Paz and the Portes del (or Portes de) Paco, the mouth of which is at the eastern point of Lake Titicaca. Two remarkable steamer routes in the world, being 12,370 ft. above sea level. The lake is 165 m. long and from 70 to 80 m. wide and has a number of small Indian villages on its shores. The southern coast of the Peruvian coast—(the American) Central and South American Co. extending from Panama to Valparaiso, and the British West Coast Cable Co., subsidiary to the Eastern Telegraph Co., with a cable between Callao and Paita, begun in 1873 and completed in 1876, when a short line from Callao to Lima was constructed, and state ownership is assumed to 1875, when the government assumed control of all lines within the republic, some of which were subsequently leased to private companies. In all the important cities, towns and ports, but cover only a small part of the republic. The cost of erecting and maintaining telegraph lines in the sierra and montaña regions is too great to permit their extension, but the government has maintained wireless telegraphy. From Puerto Bermudez, on the Pachitea or Pichis river, the terminus of a government road and telegraph line, a wireless system connects with Massisse on the Ucayali, and thence with Iquitos, on the Marañon—a distance of 930 m. by steamer, which is about 300 miles by direct communication between the three radiographic stations. This service was opened to Iquitos on the 8th of July 1908, the first section between Puerto Bermudez and Massisse having been announced a success. The Peruvian telegraph system is now under the control of the Bolivian government. The use of the telephone is general, 5236 m. being in operation in 1906. The postal service is unavoidably limited and defective, owing to the rugged character of the country, its sparse population, and the distance between centers of communication. However, however, and in the large cities and towns, it compares well with other South American countries. Peru belongs to the international postal union, and had in 1906 a money order and parcel exchange service, but it has no telegraph service with the United States. The foreign mail service is that an extra charge of 2 cents for each letter and 1 cent for each post-card is collected when they are sent across the isthmus of Panama. No charge is made for the transmission of newspapers or periodicals. Both the domestic and interoceanic mail service is conducted by the government post office, and at a rate of 1 cent for the first 20 grams and 2 cents for each additional 10 grams, or 10 cents to foreign countries in the postal union.

**Commerce.**—Owing to political disorder, difficulty in land communications, and the inheritance of vicious fiscal methods from earlier administration, the commerce of Peru has been slow and erratic. There are many ports on the coast, but only eight of them are rated as first class, viz. Callao, Iquitos, Eten, Pucayuco, Salaverry, Callao, Pisco, Mollendo and Ilo, five of which at a port of call for foreign coast steamers. The inland port of Iquitos, on the Marañon, is also rated as first class, and enjoys special privileges because of its distance from the national
capital. The second-class ports are Tumbes, Talara, Pimentel, Chimbo, Tumbes, El Abdal, Las Carreras, and Pucallpa. The greatest part of its foreign trade, its harbour, one of the best on the west coast of South America, has been greatly improved by the port works begun under the administration of President Balta. Places far inland, such as Ayacucho and Hawas, have been well connected with others, for the most part, are open roads or unsheltered bays. Mollendo is a shipping port for Bolivian exports sent over the railway from Puno. There were 12 foreign steamship lines trading at Puno in the year 1898. The trade is carried on by vessels of about 100 tons and has been reduced down the coast at frequent intervals and carrying much of its coastwise traffic. Foreign sailing vessels since 1886 have not been permitted to engage in this traffic, but permission is given to steamship vessels. Journeys under the contract of the Chilean government were allowed in 1919, but their number was limited to 300. In 1920, 500 such vessels were licensed to trade on the coast. The exports of 1920 were valued in $17,407,870. The exports of 1920 were valued at $17,407,870.

Livestock. — Although her mining industries have been the longest and most widely carried on, the principal source of Peru's wealth is largely dependent on the climate and the peculiar conditions of its civilization, but irrigation has been successfully employed in the fertile valleys of the coast.

Forestry. — Sugar-cane is cultivated in most of the coastal valleys, and with exceptional success in those of the Canete, Rimac, Chanchay, Huar, Se, Santa, Chicama, Pacasmayo and Chiclayo. Some of the large estates are owned and worked by British subjects. The railroad has opened up a new source of supplies, and the recovery soon followed the termination of the war and the output has been steadily increasing. At the outbreak of the war the production was about 15,000 tons; in 1895 the production of sugar and sugar-refined sugar amounted to 16,000 tons. In 1906 the production reached 189,418 metric tons. Next in importance is cotton, which is grown along the lower part of the Peruvian coast, and chiefly in the departments of Ancash and La Libertad. Rice is an important crop in the inundated lands of Lambayeque and La Libertad. It is a universal article of food in Peru, and the output is consumed in the country. Maize is another important food, and is generally used for the preparation of maize flour and maize meal. Beans are also grown along the lower valleys of the coast. In some places two or three crops a year are obtained. It is the staple food everywhere, and little is exported. It is largely used in the manufacture of chicata, a fermented drink, which is consumed all over the country, especially in the department of Piura, in the montaña departments of Loreto, Amazonas and Cajamarca. The local consumption is large and the export small. Another montaña product is coffee, whose success is due to the treatment it receives in the plantations. A perfect quality of beans is produced in the coastal valleys of the Andes, especially in the Chanchamayia valley. Cacao is another montaña product, although it is grown in the warm valleys of the Andes, but the export is small. Coffee beans are produced in the coast of the coffee and cacao must largely increase. Coca (Erythroxylon coca) is a plant peculiar to the eastern Andean slopes of Bolivia and Peru, where it has long been cultivated for its leaves, which give the native a stimulating effect. The leaves are extensively grown throughout the sierra region, where coca is used by the natives as a stimulant. The Cholos are never without it, and with it are able to perform incredible tasks with little food. The common method of cultivation is by digging in the ground to a depth of about 2 feet, and covering it with a layer of ashes. The demand for their commercial production is limited to grapes and olives. Grapes are produced in many of the irrigated valleys of the coast, such as Chinchina, Lurinhuana, Ica, Tito, Majes, Andacay, Paracas, and Paracas, and are extensively cultivated in the sierra region, where coca is used by the natives as a stimulant. The fruit is commonly used for the manufacture of oil, which is consumed in the country, and only a small part is exported. Were large markets available, other fruits such as oranges, lemons, limes, bananas, and papayas would undoubtedly be extensively cultivated. The sierra region, wheat, barley, oats, quinoa (Chenopodium quinoa), alfalfa, Indian corn, oca (Oxalis tuberosa) and potatoes are the principal products. Wheat is widely grown but the output is not large. Barley and oats are grown for forage, but for this purpose alfalfa has become the staple, and without it the mountain pack is impossible. The potato, the Andean vegetable par excellence, is grown at elevations of 2,200 to 3,600 feet; and its grain is an important food among the upland natives. Potatoes are grown everywhere in the sierra, and with quinoa are the only crops that can be raised in the great altiplano, which is mostly barren. Quinoa, known as cassava in the West Indies and mandioc in Brazil, is also widely cultivated for food and for the manufacture of starch.

There are good pastures in the sierra, and cattle have been successfully introduced into the more remote valleys. The bright yellow sunlight of 80,000 hours of solar radiation annually is the source of Peru's wealth. Bolivia, generally speaking, is a country of low temperatures, and the cattle are commonly small and hardy. The Peruvian sheep are reared in a somewhat smaller range, especially in the Andes, and, like the Mexican cattle, are able to bear unfavourable conditions. The sheep are reared on a somewhat larger range, especially in the Andes, and, like the Mexican cattle, are able to bear unfavourable conditions. The sheep are reared on a somewhat larger range, especially in the Andes, and, like the Mexican cattle, are able to bear unfavourable conditions. commercial asset of the republic. The large revenues derived from these sources undoubtedly became a cause of weakness and demoralization and eventually resulted in bankruptcy and the loss of Tarapaca. The deposits have been partially exhausted by the large shipments of over a half-a-century, but the export in 1905 was 73,390 tons, valued at £285,729.

Minning.—Mining was the chief industry of Peru under Spanish rule. The Inca tribes were an agricultural and pastoral people, but the aboriginal exploitation of silver as well as gold was on a very small scale, and the conquest shows that mining must have received considerable attention. They used these precious metals in decorations and as ornaments, but apparently attached no great value to them. The use of copper was more general, and they produced copper and especially, some of the great copper deposits. Immediately following the Spanish invasion the Andean region was thoroughly explored, and with the assistance of Indian slaves thousands of mines were opened, many of them failures, some of them becoming famous. There were顽强 and splendid attempts to capture the silver and gold, and to equalize the colonies against Spanish rule, owing to the unsettled state of the country, and this decline continued in some measure to the end of the century. The mining laws of the colonial regime and political disorder together raised a barrier to the employment of the large amount of capital needed, while the frequent outbreaks of civil war made it impossible to work any large enterprise because of its interference with labour and the free use of ports and roads. The Peruvians were impoverished, and under such conditions foreign capital could not be secured. In 1876 new mining laws were enacted which gave better titles to mining properties and better regulations for their operation, but the outbreak of the war with Chile and the distribution of the people by the dispersal of disorganization and partisan strife defeated their purpose. Another new mining code was adopted in 1901, and this, with an improvement in political and economic conditions, has led to a renewal of mining enterprise.

Economically the whole Andean region of Peru is mineral-bearing—a region 1500 m. long by 200 to 300 m. wide. Within these limits are to be found most of the minerals known—gold, silver, quicksilver, copper, lead, zinc, iron, manganese, wolfram, bismuth, thoria and thorium, iron, coal, and ample supplies of salt, sulphur, borax, nitrates and petroleum. Gold is found in lodes and alluvial deposit; the former on the Pacific slope at Salpo, Otuzco, Huaylas, Yungay, Ocros, Chorrillos, Cañete, Ica, Nasca, Andahuaylas, Arequipa, and on the eastern slope in the districts of Marañon, in the districts of Pataz, Huánuco, Chumquitambo, Huancavelica, Cuzco, Cotabamba, Aymares, Paucartambo, Santo Domingo and Sandia; the latter wholly on the Amazon slope, in the country about the Province of Piura, and in the departments of Cajamarca, Junin, Huancavelica, Ica, Arequipa, Andahuaylas, and the department of Pasco. Nearly all of the Cerro de Pasco mines have been purchased by American capitalists. A smelting plant was erected in the vicinity of Cerro de Pasco designed to treat 10,000 tons of ore daily, a railway was built to carry the ore to the coast, and a large bank was organized to carry on the mining enterprise. In 1903, the Cerro de Pasco mines were producing 200,000 tons of silver, and the annual product being about 670 tons for a long period. The metal generally occurs as sulphide of mercury (cinnabar), but the ores vary greatly in richness—from 2% to 20%. The annual production has fallen to a small fraction of the former output, its value in 1905 being £343,000. In 1906 £495,000. The copper deposits of Peru long remained undeveloped through want of cheap transport and failure to appreciate their true value. The principal copper-bearing districts are Chimbote, Huancayo, Huaraz, Huallanca, Junin, Huancavelica, Ica, Arequipa, Andahuaylas, and the department of Pasco. Of the high, bleak regions of the Andes, the Junin district is the best known and includes the Cerro de Pasco, Yauli, Morococha and Huarmey groups of mines, all finding an outlet to the coast over the Oraya railway. In 1903, the Cerro de Pasco mines had been invested with £285,729. The Cerro de Pasco mines are subjected to some authorities to be the largest copper deposit in the world. In the smelting works at Cerro de Pasco there are large works at Casapalca, between Oroya and Lima, which belong to a British company, and smaller plants at Huallanca and Huarmey. The production of copper is steadily increasing, the returns for 1903 being £343,000, and for 1904 £495,000. Of other metals, lead is widely distributed, its chief source being a high grade galena accompanied by silver. Iron ores are found in Piura, the Huaylas valley, Aya, with the former, and the latter by the depression, which have not been worked through lack of fuel. Sulphur deposits exist at the Sechura desert region, on the coast, and extensive borax deposits have been developed in the department of Arequipa. Coal has been found in extensive beds near Piura, Salaverry, Chimbote, Huarmey and Pisac Lake, and a large deposit has been opened on the Tumaco or the valley of Lake Titicaca in the department of Puno. The most productive of the Piura wells are at Talara and Zorritos, where refineries have been established. The crude oil is used on some of the Peruvian railways.

The number of mining claims (perpetenias) registered in 1907 was 12,858, according to official returns, each subject to a tax of 30 soles, or £1 p.a., the payment of which secures complete ownership of the minerals found at the mines. The quantity of such minerals as quicksilver (practically about (5 acres) in the case of mineral veins or lodes, and 200 x 200 metres (about 10 acres) for coal, alluvial gold and other deposits. The licences are commonly obtained from the Cholos, or Indian tribes, the buyers of the claims, and the Cuzco, Puno, and Trujillo. The plating of Panama hats from the specially prepared fibre of the "toquilla" palm is a domestic industry among the Indians at Catacaos (Piura) and Eten (Lambayeque). Coarser straw hats are made at other places, as well as hammocks, baskets, and hammocks.

Manufactures.—The manufacturing industries of Peru are confined chiefly to the treatment of agricultural and mineral products—the former including cotton, wool, sugar, and other produce, and the latter, owing to the large deposits of nitrates, salt, and coal, (in the form of coal-tar products). There are cotton factories, sugar factories, sugar cane, textiles, flax, wool, and hemp, and the output in this direction is large. The production of raw cotton is considerable, and the factories are extensively worked in the departments of Lima, Callao, and Arequipa. There are sugar factories at Lima, Callao, Cuzco, and Lima, and the consumption of beer is increasing. There are large quantities of cotton, wool, and hemp, and the export of raw cotton is large.

Government.—Peru is a centralized republic, whose supreme law is the constitution of 1856. Like the other states of South America its constitution provides for popular control of legislation and the execution of the laws through free elections and comparatively short terms of office, but in practice these safeguards are often set aside and dictatorical methods supersede all others. Nominally the people are free and exercise
souvereign rights in the choice of their representatives, but the ignorance of the masses, their apathy, poverty and dependence upon the great land proprietors and industrial corporations practically defeat these fundamental constitutional provisions. Citizenship is accorded to all Peruvians over the age of 21 and to all married men under that age, and the right of suffrage to all citizens who can read and write, or possess real estate or workshops, or pay taxes. In all cases the exercise of citizenship is regulated by law.

The government is divided into three independent branches, legislative, executive and judicial, of which force of circumstances the executive has become the dominating power. The executive branch consists of a president and two vice-presidents elected for terms of four years, a cabinet of six ministers of state appointed by the president, and various subordinate officials who are under the direct orders of the president. The president is chosen by a direct popular election and cannot be re-elected to succeed himself. He must be not less than 35 years of age, a Peruvian by birth, in the enjoyment of all his civil rights, and domiciled in the republic ten years preceding his election. The immediate supervision and despatch of public administration is afforded by his cabinet ministers—interior, foreign affairs, war and marine, finance, and commerce, justice and public instruction, and public works and promotion (fomento). The execution of the laws in the departments and provinces, as well as the maintenance of public order, is entrusted to prefects and sub-prefects, who are appointees of the president. A vacancy in the office of president is filled by one of the two vice-presidents elected at the same time and under the same conditions. Inability of the first vice-president to assume the office opens the way for the second vice-president, who becomes acting president until a successor is chosen. The vice-presidents cannot be candidates for the presidency during their occupancy of the supreme executive office, nor can the ministers of state, nor the general-in-chief of the army, while in the exercise of their official duties.

The legislative power is exercised by a national Congress—senate and chamber of deputies—meeting annually on the 28th of July in ordinary session for a period of 90 days. Senators and deputies are invariable in the exercise of their duties, and cannot be arrested, tried, or condemned to death, or imprisoned, while in session, including the month preceding and following the session, except in flagrant delicto. Members of Congress are forbidden to accept any employment or benefit from the executive. Senators and deputies are elected by direct vote—the former by departments, and the latter in proportion to the population. With both are elected an equal number of substitutes, who assume office in case of vacancy.

Departments with eight and more provinces are entitled to four senators, those of four to seven provinces three senators, those of three to six provinces two senators, and those of two provinces one senator. The deputys are chosen to represent 15,000 to 30,000 population each, but every province must have at least one deputy. Both senators and deputies are elected for terms of six years, and are re-elected at the expiration of their terms, and are eligible for unlimited periods of time. They hold their offices in good standing of some head of some public court, nor any member of the ecclesiastical hierarchy, nor any judge or "fiscal" of superior and first-instance courts from their judicial districts, nor any military officer from the district where he holds his official appointment at the time of election. No country is provided with two or more colonies against each other. All official absences than is Peru, and yet few countries suffered more from political disorder during the 19th century. The president has no veto power, but has the right to return a law to Congress with comments within a period of ten days. Should the act be again passed without amendments it becomes law; if, however, the suggested amendments are accepted the act must go over to the next session. Congress may also sit as a court of impeachment—the Senate hearing and deciding the case, and the chamber acting as prosecutor. The president, ministers of state and judges of the supreme court may be brought before this court.

Justice.—The judiciary is composed of a supreme court, superior courts and courts of first instance, and justices of the peace. The supreme court is established at the national capital and consists of 11 judges and 2 "fiscals" or prosecutors. The judges are appointed for terms of eight years by the president and confirmed by the home. The judges of the superior courts are chosen by the president from the list of nominees submitted by the supreme court. Questions of jurisdiction between the superior and supreme courts, questions of jurisdiction between the president and police officials throughout the republic are also appointees of the president and are under his orders.

Army.—After the Chilian War the disorders fomented by the rebellion, by which, as reorganized, consists of 4000 officers and men, divided into seven battalions of infantry of 300 men each, and three regiments of light artillery, one regiment of mountain artillery of 590 men, with six batteries of mountain guns. The reorganization of the army was carried out by 10 officers and 94 non-coms. of the French army, known as the French military instruction, and other school of military instruction at Chorrillos and all branches of military instruction. The army is divided into four military districts, viz., Lima, Callao, Trujillo, and Leoncio Vela, and the national guard (35 to 50 years). The regular force is maintained by perpetual drawings from the lists of young men 19 years of age and upwards, who are called to active service for the first time. The direction of military affairs is entrusted to a general staff, which was reorganized in 1904 on the lines adopted by the great military powers of Europe. The republic is divided into four military districts with the seat of their capital and legislative. The national guard, which, since 1895, has had the adoption of any measure for its rebuilding. In 1908 it consisted of only five vessels. The naval school at Callao is under the direction of an officer of the French navy. In addition to the cost of the government, the national debt has been diminished, with a consequent improvement in the financial state of the country. The public revenues are derived from customs, taxes, various inland and consumption taxes, state monopolies, the import and export duties, and judicial fines. The different customs taxes include import and export duties, surcharges, import duties; &c.; the inland taxes comprise consumption taxes on tobacco, sugar and matches, stamps and stamped paper, currency, and various property, finances, transfers of property, &c., and the state monopolies over the import and export of precious stones. In 1908 a loan of $600,000 was floated in Germany for additions to the navy. The growth of receipts and expenditures is shown in the following table:

The revenues of 1896 were only £1,128,714. The foreign debt began with a small loan of £1,200,000 in 1822, and another of £1,500,000 in 1825. The only loan £1,616 of 1866 was placed. At the end of the war, these loans, amounting to £8,000,000, le
1830 the debt and accumulated interest owing in London amounted to £3,310,767, in addition to which there was a home debt of 17,183,397 dollars. In 1848 the two London loans and accumulated interest were covered by a new loan of £3,736,400, and the home debt was also covered, the government giving ample resources. Lavish expenditure followed and the government was soon anticipating its revenues by obtaining advances from guano consignees, usually on unfavourable terms, and then floating loans to cover the deficits thus incurred. In 1862 £5,500,000 and in 1864 still another loan of this character was issued, nominally for £10,000,000, of which £7,000,000 only were issued. Then followed the ambitious schemes of PresidentBalta, which with the result of a further loan covering the total foreign debt of £9,000,000, on which the annual interest charge was about £1,500,000, a sum wholly beyond the resources of the country. In 1876 interest payments on account of this debt were suspended and in 1878 it was agreed with Chile to cancel the Peruvian share of its foreign debts. On the sources of income—the guano deposits and the Tarapacá nitrates. In 1889 the total foreign debt, including arrears of interest, was £54,000,000, and in the following year a contract was signed with the British government to pay to the commercial house of Fife and Co. of London, under the title of "Sierra de Guano," £1,500,000 for the value of guano at the rate of 83,397 per cent. The income from guano was used to meet the interest charge on the national debt at a discount of 87½ per cent. The British Government had been asked by the Peruvian Government to generate revenue from its guano deposits. The British took control of the exploitation of the guano beds and paid the government a lump sum of £2,310,767, and an annual fee of £65,000 to meet the interest charge on the national debt. The guano was used to meet the interest charge on the national debt. The government was able to meet the interest charge on the national debt, and in addition, it was able to generate revenue from the guano deposits. In 1898, the British government was able to pay off the national debt, and the guano deposits were returned to the Peruvian government.

Currency.—The single gold standard has been in force in Peru since 1897 and 1898, silver and copper being used for subsidiary coinage. The monetary unit is the Peruvian pound (libra) which is divided into twenty centavos. Each gold coin was worth about 800 centavos, and the silver coin was worth about 250 centavos. The government also minted silver coins of various denominations, including half and one centavos, which were used for smaller transactions.

Weights and Measures.—The French metric system is the official standard in Peru. The principal unit of length is the metre, and the principal unit of weight is the kilogram. The yard is divided into 36 inches, and the mile is divided into 5,280 feet. The British pound is divided into 20 shillings, and the shilling into 12 pence. The Peruvian peso is divided into 100 centavos.

History.—Cyclopean ruins of vast edifices, apparently never completed, exist at Huánuco near the southern shore of Lake Titicaca. Remains of a similar character are found at Huaraz in the north of Peru, and at Cusco, Ollantaytambo and Huánuco between Huaraz and Huánuco. These works appear to have been erected by powerful sovereigns with unlimited command of labour, possibly with the object of giving employment to subjugated people, while feeding the vanity or pleasing the taste of the conqueror. Of their origin nothing is historically known. It is probable, however, that the settlement of the Cuzco valley and district by the Incas or "people of the sun" took place some 300 years before Pizarro landed in Peru. The conquering tribe or tribes had made their way to the sierra from the plains, and found themselves a new land sheltered from attack amidst the lofty mountains that hem in the valley of Cuzco and the vast lake of Titicaca, situated 12,000 ft. above the sea level. The first historical records show us these people already possessed of a considerable civilization, and speaking two allied languages, Aymara and Quichua. The expansion of the Inca rule and the formation of the Peruvian Empire was of modern growth at the time of the Spanish conquest, and dated from the victories of Pachacutec Inca, who lived about a century before Huayna Capac, the Great Inca, whose death took place in 1526, the year before Pizarro first appeared on the coast. His consolidated empire extended from the river Ancasuyuy north of Quito to the river Maule in the south of Chile. The Incas had an elaborate system of state-worship, with a ritual, and frequently recurring festivals. History and tradition were preserved by the bards, and dramas were enacted before the sovereign and his court. Roads with post-houses at intervals were made over the wildest mountain-ranges and the bleakest deserts for hundreds of miles. A well-considered system of land-tenure and of colonization provided for the wants of all classes of the people. The administrative details of government were minutely and carefully organized, and accurate statistics were kept by means of "quipus" or system of knots. The edifices displayed marvellous building skill, and their workmanship was such that modern architects have nothing to say in the way of stone-cutting and fitting, while the skill and accuracy displayed in the Inca structures of Cuzco. As workers in metals and as potters they displayed infinite variety of design, while as cultivators and engineers they excelled their European conquerors. (For illustrations see America, Plate V.)

The story of the conquest has been told by Prescott and Himself, who give ample references to original authorities; it will be sufficient here to enumerate the dates of the leading events. On the 10th of March 1536 the contract for the conquest of Peru was signed by Francisco Pizarro, Diego de Almagro and Hernando de Lugo, Gaspar de Espinosa supplying the funds. In 1537 Pizarro, after enduring fearful hardships, first reached the coast of Peru at Tumbes. In the following year he went to Spain, and on the 26th of July 1539 the capitulation with the Crown for the conquest of Peru was executed. Pizarro sailed from San Lucar with his brother Almagro in January 1530, and landed at Tumbes in 1531. The civil war between Almagro and Atahualpa, the sons of Huayna Capac, had been fought out in the meanwhile, and the victorious Atahualpa was at Cajamarca on his way to Cuzco. On the 15th of November 1532 Pizarro with his little army, made his way to Cajamarca, where he received a friendly welcome from the Inca, whom he treacherously seized and made prisoner. He had with him only 183 men. In February 1533 his colleague Almagro arrived with reinforcements. The murder of the Inca Atahualpa was perpetrated on the 29th of August 1533, and on the 15th of November Pizarro entered Cuzco. He allowed the rightful heir to the empire, Manco, the legitimate son of Huayna Capac, to be solemnly crowned on the 24th of March 1534. Almagro then undertook an expedition to Chile, and Pizarro founded the city of Lima on the 18th of January 1535. In the following year the Incas made a brave attempt to expel the invaders, and closely besieged the Spaniards in Cuzco during February and March. But Almagro, returning from Chile, raised the siege on the 18th of April 1537. Immediately afterwards a dispute arose between the brothers, Francisco, Juan and Gonzalo Pizarro and Almagro
as to the limits of their respective jurisdictions. An interview 
took place at Mala, on the sea-coast, on the 13th of November 
1537, which led to no result, and Almagro was finally defeated 
in the battle of Las Salinas near Cuzco on the 26th of April 1538. 
His execution followed. His adherents recognized his young 
half-caste son, a gallant and noble youth generally known as 
Almagro the Lad, as his successor. Bitterly disappointed, they 
conspired at Lima and assassinated Francisco Pizarro on the 
26th of June 1541. Meanwhile Vaca de Castro had been sent 
out as governor of Peru by Charles V., and on hearing of the 
murder of Pizarro he assumed the government of the country. 
On the 16th of September 1542 he defeated the army of Almagro 
the Lad in the battle of Chupas near Guamanga, and the boy 
was beheaded at Cuzco.

Charles V. enacted the code known as the "New Laws" in 
1542. "Encomiendas," or grants of estates on which the 
inhabitants were bound to pay tribute and give 
personal service to the grantee, were to pass to the 
Crown on the death of the actual holder; a fixed sum was 
to be assessed as tribute; and forced personal service was 
forbidden. Blasco Nuñez de Vela was sent out, as first viceroy 
of Peru, to enforce the "New Laws." Their promulgation 
awoke a storm among the conquistadores, Gonzalo Pizarro 
in rebellion, and entered Lima on the 28th of October 1544. 
The viceroy fled to Quito, but was followed, defeated and killed 
at the battle of Anauquito on the 18th of January 1546. The "New Laws" were weakly revoked, and Pedro de la Gasca, as 
first president of the Audiencia (court of justice) of Peru, 
was sent out to restore order. He arrived in 1547, and on the 8th 
of April 1548 he routed the followers of Gonzalo Pizarro on the 
plain of Sacahuaman near Cuzco. Gonzalo was executed on 
the field. La Gasca made a redistribution of "encomiendas" to 
the loyal conquistadores, which caused great discontent, and left 
Peru before his scheme was made public in January 1550. 
On the 23rd of September 1551 Don Antonio de Mendoza arrived as 
second viceroy, but he died at Lima in the following July. 
The country was then ruled by the judges of the Audiencia, and 
a formidable insurrection broke out, headed by Francisco Hernandez 
Giron, with the object of maintaining the right of the 
conquistadores to exact forced service from the Indians. In May 
1554 Giron was joined in arms by the judges at Chuquinga, but 
he was hopelessly routed at Purococha, October 1554, 
captured, and on the 7th of December executed at Lima. 
Don Andres Hurtado de Mendoza, marquis of Cañete, entered 
Lima as third viceroy of Peru on the 6th of July 1555, and ruled 
with an iron hand for six years. All the leaders in former 
disturbances were sent to Spain. Corregidores, or governors 
of districts, were ordered to try summarily and execute every 
turbulent person within their jurisdictions. All unemployed 
persons were sent on distant expeditions, and moderate "en-
comiendas" were granted to a few deserving officers. At 
the same time the viceroy wisely came to an agreement with Sayri 
Tupac, the son and successor of the Inca Manco, and granted 
him a pension. He took great care to supply the natives with 
priests of good conduct, and promoted measures for the 
establishment of schools and the foundation of towns in the different 
provinces. The cultivation of wheat, vines and olives, and 
European domestic animals were introduced. The next viceroy 
was the Conde de Nieva (1561-1564). His successor, the 
licentiate Lope Garcia de Castro, who only had the title 
of governor, ruled from 1564 to 1569. From this time there 
was a succession of viceroys until 1824. The viceroys were chief 
judges, but in legal matters they had to consult the Audiencia 
of judges, in finance the Tribunal de Cuentas, in other 
branches of administration the Juntas de Gobierno and de 
Guerra.

Don Francisco de Toledo, the second son of the count of 
Oropesa, entered Lima as viceroy on the 26th of November 1560.

Toledo's Administration.

Toledo, who had succeeded his brother Sayri Tupac, might 
become a focus of rebellion, he seized the viceroy, and unjustly beheaded the last of the Incas in the square

of Cuzco in the year 1571. After a minute personal inspection 
of every province in Peru, he, with the experienced aid of the 
learned Polo de Ondegardo and the judge of Matienza, 
established the system under which the native population of Peru 
was ruled for the two succeeding centuries. His Libro de 
Tasos fixed the tribute to be paid by the Indians, exempting 
all men under eighteen and over fifty. He found it necessary, 
in order to secure efficient government, to revert in some measure 
to the system of the Incas. The people were to be directly 
governed by their native chiefs, whose duty was to collect the 
tribute and exercise magisterial functions. The chiefs or "curacas" had subordinate native officials under them called "pichca-pachacas" over 500 men, and "pachacas" over 100 men. The office of curaca or cacique was made hereditary, and its possessor enjoyed several privileges. Many curacas were descended from the imperial family of the Incas, or from great nobles of the Incaical court. In addition to the tribute, which was in accordance with native usage, there was the "mita," or forced labour in mines, farms and manufactories.

Toledo enacted that one-seventh of the male population of a 
village should be subject to conscription for this service, but 
they were to be paid, and were not to be taken beyond a specified 
distance from their homes.

The Spanish kings and viceroys desired to protect the people from tyranny, but they were unable to prevent the rapacity and lawlessness of distant officials and the country was depopulated by the illegal methods of enforcing the mita. Toledo was succeeded in 1581 by Don 
Martin Henriquez, who died at Lima two years afterwards. The Spanish colonies suffered from the strict system of monopoly 
and protection, which was only slightly relaxed by the later Bourbon kings, and from the arbitrary proceedings of the 
Inquisition. Between 1581 and 1776 as many as fifty-nine heretics were burned at Lima, and there were twenty-nine 
"autos"; but the Inquisition affected Europeans rather than 
natives, for the Indians, as catechumens, were exempted from 
its terrors. The curacas sorrowfully watched the gradual extinction 
of their people by the operation of the mita, protesting from 
time to time against the exactions and cruelty of the Spaniards. 
At length a descendant of the Incas, who assumed the name of 
Tupac Amaru, rose in rebellion in 1780. The insurrection lasted 
until July 1783, and cruel executions followed its suppression. This was the last uprising of the Incas to disturb the 
Spanish yoke, and the rising was by no means general. The army which 
overthrew Tupac Amaru consisted chiefly of loyal Indians, and 
the rebellion was purely anti-Spanish, and had no support from 
the Spanish population. The movement for independence, which slowly gained force during the opening decade of the 19th 
century, did not actually become serious until the conquest of 
Spain by the French in 1807-1808. The Creoles (Criollos) or 
American-born Spaniards had for long been aggrieved at being 
shut out from all important official positions, and at the restrictions 
placed upon their trade, but the bulk of the Creole population 
was not disloyal.

Peru was the centre of Spanish power, and the viceroy had 
his military strength concentrated at Lima. Consequently the 
insurrections in the more distant provinces, such as 
Chile and Buenos Aires, were the first to declare 
themselves independent, in 1816 and 1817. But 
the destruction of the viceroy's power was essential to their 
continued independence. The conquest of the Peruvian 
coast must always depend on the coast. A fleet of 
armored ships was fitted out at Valparaiso in Chile, under 
the command of Lord Cochrane (afterwards earl of Dundonald) and 
offered by Englishmen. It convoyed an army of 
Argentine troops, with some Chileans, under the command of the Argentine 
general, San Martin, which landed on the coast of Peru in 
September 1820. San Martin was enthusiastically received, 
and the independence of Peru was proclaimed at Lima after 
the viceroy had withdrawn (July 28, 1821). On the 20th of 
September 1822 San Martin resigned the protectorate, with 
which he had been invested, and on the same day the first
congress of Peru became the sovereign power of the state. After a short period of government by a committee of three, the congress elected Don José de la Riva Agüero to be the first president of Peru on the 28th of February 1823. He displayed great energy in facing the difficulties of a turbulent situation, but was unsuccessful. The aid of the Colombians under Simón Bolívar was sought, and Agüero was deposed.

Bolívar arrived at Lima on the 1st of September 1823, and began to organize an army to attack the Spanish viceroy in the interior. On the 6th of August 1824 the cavalry action of Junín was fought with the Spanish forces under the command of a French adventurer, General Canterac, near the shores of the lake of Chinchay-cocha. It was won by a gallant charge of the Peruvians under Captain Suárez at the critical moment. Soon afterwards Bolívar left the army to proceed to the coast, and the final battle of Ayacucho (Dec. 6, 1824) was fought by his second in command, General Sucre. The viceroy and all his forces were taken prisoners, and the Spanish power in Peru came to an end.

General Bolívar ruled Peru with dictatorial powers for more than a year, and though there were cabals against him there can be little doubt of his popularity. He was summoned back to Colombia when he had been absent for five years and, in spite of protests left the country on the 3rd of September 1826, followed by all the Colombian troops in March 1827.

General José de Lamar, who commanded the Peruvians at Ayacucho, was elected president of Peru on the 24th of August 1827, but was deposed, after waging a brief but disastrous war with Colombia on the 7th of June 1829. General Agustín Gamarra, who had been in the Spanish service, and was chief of the staff in the patriot army at Ayacucho, was elected third president on the 31st of August 1829. For nineteen years, from 1829 to 1844, Peru was painfully feeling her way to a right use of independence. The officers who fought at Ayacucho, and to whom the country felt natural gratitude, were all-powerful, and they had not learned to settle political differences in any other way than by the sword. Three men, during that period of probation, won a prominent place in their country's history, Generals Agustín Gamarra, Felipe Santiago Salaverry, and Andrés Santa Cruz. Gamarra, born at Cuzco in 1785, never accommodated himself to constitutional usages; but he attached to himself many loyal and devoted friends, and, with all his faults he loved his country and sought its welfare according to his lights. Salaverry was a very different character. Born at Lima in 1806, of pure Basque descent, he joined the patriot army before he was fifteen and displayed his audacious valor in many a hard-fought battle. Feeling strongly the necessity that Peru had for repose, and the guilt of civil dissension, he wrote patriotic poems which became very popular. Yet he too seized the supreme power, and perished by an iniquitous sentence on the 18th of February 1836. Andrés Santa Cruz was an Indian statesman. His mother was a lady of high rank, of the family of the Incas, and he was very proud of his descent. Successful as a general in the field, he nevertheless possessed remarkable administrative ability and for nearly three years (1836–1839) realized his lifelong dream of a Peru-Bolivian confederation. But the strong-handed intervention of Chile on the ground of assistance rendered to rebels, but really through jealousy of the confederation, ended in the defeat and overthrow of Santa Cruz, and the separation of Bolivia from Peru. But Peruvian history is not confined to the hostilities of these military rulers. Three constitutions were framed—in 1828, 1833 and 1839. Lawyers and orators are never wanting in Spanish-American states, and revolution succeeded revolution in one continuous struggle for the spoils of office. An exception must be made of the administration of General Ramón Castilla, who restored peace to Peru, and showed himself to be an honest and very capable ruler. He was elected constitutional president on the 20th of April 1845. Ten years of peace and increasing prosperity followed. In 1849 the regular payment of the interest of the public debt was commenced, steam communication was established along the Pacific coast, and a railroad was made from Lima to Callao. After a regular term of office of six years of peace and moral and material progress Castilla resigned, and General José Echenique was elected president. But the proceedings of Echenique's government in connexion with the consolidation of the internal debt were disapproved by the nation, and, after hostilities which lasted for six months, Castilla returned to power in January 1855. From December 1856 to March 1858 he had to contend with and subdue a local insurrection headed by General Agustín Vivanco, but, with these two exceptions, there was peace in Peru from 1844 to 1859, a period of thirty-five years. Castilla retired at the end of his term of office in 1862, and died in 1868. On the 2nd of August 1868 Colonel Juan Balta was elected president. With the vast sum raised from guano and nitrate deposits President Balta commenced the execution of public works, principally railroads on a gigantic scale. His period of office was signalized by the opening of an international exhibition at Lima. He was succeeded (Aug. 2, 1872) by Don Manuel Pardo (d. 1878), an honest and enlightened statesman, who did all in his power to retrieve the country from the financial difficulty into which it had been brought by the reckless policy of his predecessor, but the conditions were not capable of solution. He regulated the Chinese immigration to the coast-valleys, which from 1860 to 1872 had amounted to 36,606. He promoted education, and encouraged literature. On the 2nd of August 1876 General Mariano Ignacio Prizado (C. R. M. X.) succeeded.

On the 4th of April 1879 the republic of Chile declared war upon Peru, the alleged pretext being that Peru had made an offensive treaty, directed against Chile, with Bolivia. War with Chile, 1879-1883. The publication of the text of this treaty made known the fact that it was strictly defensive and contained no just cause of war. The true object of Chile was the conquest of the rich Peruvian province of Tarapacá, the appropriation of its valuable guano and nitrate deposits, and the spoliation of the rest of the Peruvian coast. The military events of the war, calamitous for Peru, are dealt with in the article CHILE-PERUVIAN WAR. Suffice it here to note that, after the crushing defeat of the Peruvian forces at Arica (June 7, 1880) Señor Nicolás de Pieriola assumed dictatorial powers, with General Andrés Cáceres as commander-in-chief, but the defeats at Chorrillos (Jan. 13, 1881) and Miraflores (Jan. 15) proved the Chilean superiority, and put Lima at their mercy though desultory fighting was maintained by the remnants of the Peruvian army in the interior, under direction of General Cáceres. An attempt was made to constitute a government with Señor Calderon as president of the republic and General Cáceres as first vice-president. The negotiations between this nominal administration and the Chilean authorities for a treaty of peace proved futile, the Chilean occupation of Lima and the Peruvian seaboard continuing uninterruptedly until 1883. In that year Admiral Lynch, who had replaced General Baquedano in command of the Chilean forces after the taking of Lima, sent an expedition against the Peruvians under General Cáceres, and defeated the latter in the month of August. The Chilean authorities now began preparations for the evacuation of Lima, and to enable this measure to be effected a Peruvian administration was organized with the support of the Chileans. General Ignacio Lynch was nominated to the office of president of the republic, and in October 1883 a treaty of peace, known as the treaty of Ancon, between Peru and Chile was signed. The Chilean army of occupation was withdrawn from Lima on the 22nd of October 1883, but a strong force was maintained at Chorrillos until July 1884, when the terms of the treaty were finally approved. The
principal conditions imposed by Chile were the absolute cession by Peru of the province of Tarapacá, and the occupation for a period of ten years of the territories of Tacna and Arica, the ownership of these districts to be decided by a popular vote of the inhabitants of Tacna and Arica at the expiration of the period named. A further condition was enacted that an indemnity of 10,000,000 soles was to be paid by the country finally remaining in possession—a sum equal to about £1,000,000 to-day. The Peruvians in the interior refused to recognize President Iglesias, and at once began active operations to overthrow his authority on the final departure of the Chilean troops. Affairs continued in this unsettled state until the middle of 1885. Cáceres meanwhile steadily gaining many adherents to his side of the quarrel. In the latter part of 1885 President Iglesias abdicated.

Under the guidance of General Cáceres a junta was then formed to carry on the government until an election for the presidency should be held and the senate and chamber of deputies constituted. In the following year (1886) General Cáceres was elected president of the republic for the usual term of four years. The task assumed by the new president was no sinecure. The country had been thrown into absolute confusion from a political and administrative point of view, and gradually order was restored and new conditions were reconstituted throughout the republic. The four years of office for which General Cáceres was elected passed in uneventful fashion, and in 1890 Señor Morales Bermúdez was nominated to the presidency, with Señor Solar and Señor Borgoño as first and second vice-presidents. Matters continued without alteration from the normal course until 1894, and in that year Bermúdez died suddenly a few months before the expiration of the period for which he had been chosen as president. General Cáceres secured the nomination of the vice-president Borgoño as chief of the executive for the unexpired portion of the term of the late president Bermúdez. This action was unconstitutional, and was bitterly resented by the vice-president Solar, who by right should have succeeded to the office. Armed resistance to the authority of Borgoño was immediately organized in the south of Peru, the movement being supported by Señores Nicolas de Pierola, Billinghurst, Durand and a number of influential Peruvians. In the month of August 1894 General Cáceres was again elected to fill the office of president of the republic, but gradually order was restored and ground gained. President Cáceres adopted energetic measures to suppress the outbreak: his efforts, however, proved unavailing, the close of 1894 finds the country districts in the power of the rebels and the authority of the legal government confined to Lima and other cities held by strong garrisons. Early in March 1895 the insurgents encamped near the outskirts of Lima, and on the 17th, 18th and 19th of March severe fighting took place, ending in the defeat of the troops under General Cáceres. A suspension of hostilities was then brought about by the efforts of H.B.M. consul. The loss on both sides to the struggle during these two days was 2800 killed and wounded. President Cáceres, finding his cause was lost, left the country, a provisional government under Señor Candalmo assuming the direction of public affairs.

On the 8th of September 1895 Señor Pierola was declared president of the republic for the following four years. The Peruvians were then heartily tired of revolutionary disturbances, and an insurrectionary outbreak in the district of Iquitos met with small sympathy, and was at once dispersed. The act by which the electoral law was sanctioned. By the provisions of this act an electoral committee was constituted, composed of nine members, two of these nominated by the senate, two by the chamber of deputies, four by the supreme court, and one by the president with the consent of his ministers. To this committee was entrusted the task of the examination of all election returns, and of the proclamation of the names of successful candidates for seats in congress. Another reform brought about by Pierola was a measure introduced and sanctioned in 1897 for a modification of the marriage laws. Under the new act marriages of non-Catholics solemnized by diplomatic or consular officers or by ministers of dissenting churches, if properly registered, are valid, and those solemnized before the passing of this act were to be valid if registered before the end of 1890.

Revolutionary troubles again disturbed the country in 1899, when the presidency of Señor Pioalla was drawing to a close. In consequence of dissensions amongst the members of the election committee constituted by the act of 1896, the president ordered the suppression of this body. A group of malcontents under the leadership of Senor Durand, a man who had been prominent in the revolution against General Cacères in 1894-95, conspired against the authorities and raised several armed bands, known locally as montaneras. Some skirmishes occurred between these insurgents and the government troops, the latter generally obtaining the advantage in these encounters.

In September 1899 President Pioalla vacated the presidency in favour of Señor Romañon, who had been elected to the office as a popular candidate and without the exercise of any undue official influence. President Romañon was educated at Stonyhurst in England, and was a civil engineer by profession. The principal political problem before the government of Peru was the ownership of the territories of Tacna and Arica. The period of ten years originally sanctioned by the treaty of 1881 expired without to the government. At that date the peace of Peru was so seriously disturbed by internal troubles that the government was quite unable to take active steps to bring about any solution of the matter. After 1894 negotiations between the two governments were attempted from time to time, but without any satisfactory results. The question hinged to a great extent on the qualification necessary for the inhabitants to vote, in the event of a plebiscite being called to decide whether Chilean ownership was to be finally established or the provinces were to revert to Peruvian sovereignty. Peru proposed that only Peruvian residents should be entitled to take part in a popular vote; Chile rejected this proposition, on the ground that all residents in the territories in question should have a voice in the final decision. The agreement between Chile and Bolivia, by which the disputed provinces were to be handed over to the latter country if Chilean possession was recognized, was also a stumbling-block, a strong feeling existing among Peruvians against this proceeding. It was not so much the value of Tacna and Arica that put difficulties in the way of a settlement as the fact that the national pride of the Peruvians was involved in the question of claiming all claim to this section of country. The money, about £1,000,000, could probably have been obtained to indemnify Chile if occasion for it arose.

The question of the delimitation of the frontier between Peru and the neighbouring republics of Ecuador, Colombia, and Brazil also cropped up at intervals. A treaty was signed with Brazil in 1876, by which certain physical features were accepted by both countries as the basis for the boundary. In the case of Ecuador and Colombia a dispute arose in 1894 concerning the ownership of large tracts of uninhabited country in the vicinity of the headwaters of the Amazon and its tributaries. An agreement was proposed between Peru and Ecuador in connexion with the limits of the respective republics, but difficulties were created to prevent this proposal from becoming an accomplished fact by the pretensions put forward by Colombia. The latter state claimed sovereignty over the Napo and Marañon rivers on the grounds of the ecclesiastical jurisdiction exercised over this section of territory during the period of Spanish dominion, the government of Colombia asserting that the ecclesiastical rights to which Colombia became entitled after her separation from the Spanish crown carried also the right of absolute ownership. In a treaty signed by the three interested states in 1895 a compromise was effected by which Colombia withdrew a part of the claim advanced, and it was agreed that any further differences arising out of this frontier question should be submitted to the arbitration of the Spanish crown. The later development of the boundary question is dealt with at the outset of this article.
Señor Manuel Candamo succeeded Señor Romualdo as president in 1903. In the following year he died, and on the 24th of September 1904 Señor José Pardo was installed in the presidency. In 1908 there were some insurrectionary movements at Lima and an attempt was made to assassinate President Pardo, but they were, however, suppressed without a serious outbreak. Señor Augusto Leguiva became president on the 24th of September 1908.

PERU, a city of Salle county, Illinois, U.S.A., in the north-central part of the state, on the N. bank of the Illinois River. pop. (1920), 6863 (1905 foreign-born); (1910), 7984. It is served by the Chicago, Burlington & Quincy and the Chicago, Rock Island & Pacific railways. The city is built on the face and top of a series of river bluffs. It is the seat of St Bede College (Roman Catholic, opened in 1891), conducted by Benedictine fathers. In a large public park there is a bronze monument in memory of the soldiers of Peru who died in the Civil War. There are extensive coal-mines in the vicinity; and the city includes various manufactures. Peru was first settled about 1827, was incorporated in 1845, and re-incorporated in 1890.

PERU, a city and the county-seat of Miami county, Indiana, U.S.A., about 75 m. N. of Indianapolis, on the Wabash River. pop. (1910 U. S. census), 10,510. Peru is served by the Chicago Cincinnati & Louisville, the Lake Erie & Western and the Wabash railways (each of which maintains shops here), and by electric lines to Indianapolis, Warsaw and other cities. The city has a Carnegie library, a railway Young Men's Christian Association, and a hospital for the employes of the Wabash railroad. There is a city park on the river, and a m. east of the city is Boyd park, an amusement resort. Peru is an important grain and produce market, and has various manufactures.

In 1905, the value of the factory products was $1,763,417 (72.3% more than in 1900). Petroleum is found in the vicinity. Peru was settled in 1844 and was chartered as a city in 1867.

PERUGIA (anc. Perusia), a city and archiepiscopal see of Italy, the capital of the province of Perugia (which forms the entire compartmento of Umbria) situated 1444 ft. above sea-level. Pop. (1906), 22,321 (town); 65,527 (commune). The town is finely situated upon a group of hills nearly 1000 ft. above the valley of the Tiber. Its outline is very irregular; from the centre of the town, at the junction of several ridges, parts of it extend for a considerable distance along their summits, being divided from one another by deep valleys. This is the extent enclosed by the medieval walls; within them are considerable remains of the lofty terrace walls of the Etruscan period. The so-called Arco di Augsto is a town gate with a Decorated superstructure, perhaps of the Etruscan period, bearing the inscription Augustus a full force of his rarius against a Renovatable. The superstructure of a similar gate (Porta Marzia), which was removed in 1540 to make way for the cittadell, but is depicted in a fresco by Benedetto Bonfigli (between 1461 and 1477), was re-erected in the substructure walls of the cittadell itself. It bears the inscription Colonii Vibia Augusta Perusia, so that the town must have become a colony in the reign of the emperor C. Vibia Trebonianus Gallus (A.D. 251-253), who was a native of it. Four other gates of the Etruscan period can still be traced (F. Noack in Römische Mitteilungen, 1867, 166 sqq.). In the garden of the church of S. Elisabetta was found in 1876 a fine mosaic in black on a white ground representing Orpheus in the midst of the beasts (Notizie degli scavi, 1876, 181; 1877 300). The cittadell was erected by Pope Paul III. in 1540-1546, after the plans of Antonio da Sangallo the younger, and demolished in 1860 (see Bacile di Castiglione in L’Art, 1903, 347). The Piazza del Duomo is of the primitive type; it is the cathedral of San Lorenzo, a Gothic structure of the 14th and 15th centuries, in the plan of a Latin cross, with nave and aisles of equal height; on the other the Palazzo del Municipio, presenting two fine Gothic façades, of the 14th century (though the building was not completed till 1443), with the figures of the Perugian griffin and the Guelph lion above the outside stair; and in the centre the marble fountain constructed in 1277-1280 by Arnolfo di Cambio, and adorned with statues and statues and statues by Nicolò and Giovanni Pisano. The cathedral contains the burial-place of Urban IV. and Martin IV.—the remains of Innocent III. were removed to Rome in 1802 and placed in the basilica of S. Giovanni in Laterano—and the Virgin’s wedding-ring; and at the north-east corner is a sitting statue of Pope Julius III. by Vincenzo Danti, erected in 1355 by the people of Perugia in gratitude for the restoration of their civic privileges. On the decoration of the Sala del Cambio, or old exchange, Perugino put his hand. The frescoes and the paintings have since 1863 been collected in the Pinacoteca Vannucci, established in the Palazzo del Municipio; besides a considerable number of pieces by Perugino, there are specimens of Niccolò Alunno, Bonfigli, Pinturichio, &c. A very interesting and important exhibition of Umbrian art was held here in 1907. The pictures, the werk in some splendid pieces of embroidery from S. Francesco at Assisi, the vestments of Pope Benedict XI., and the majolica of Perugia and Deruta, a village 10 m. south, were especially noteworthy (see U. Gnoli, L’Arte umbra alla mostra di Perugia, Bergamo, 1908). The illuminated MSS. of the communal library, the cathedral and the church of S. Pietro, from the 7th century onwards, were also exhibited.

The formation of the Pinacoteca Vannucci has impaired the interiors of several churches but in others it remains undiminished. San Domenico, at Gubbio, a Gothic church, has some remarkable paintings. Giovanni Pisano but rebuilt in 1614, contains the monument of Pope Benedict XI. (attributed, but probably wrongly, to Giovanni Pisano by Vasari), and in its east front a Gothic window with stained glass by Fra Bartolommeo of Perugia (1441). San Pietro de’ Cassinensi (outside the Porta Romana) is a basilica.
with nave and aisles, founded in the beginning of the 11th century by San Pietro Vincell by the site of a building of the 6th century, and remarkable for its conspicuous spire, its ancient granite and marble columns, its vaulted hall-work of 1535 by Stefano de' Zambelli da Bergamo, and its numerous pictures (by Perugino, &c.). The oratory of B. Bernardino has an early Renaissance polychrome facade, richly sculptured, of 1457-1461, by Agostino d'Antonio di Duccio di Florence. S. Severo contains Raphael's first independent fresco (1505), much damaged by restoration. The circular church of S. Angelo, with sixteen antique columns in the interior, probably dates from the middle of the 6th century. The university dates from 1307, and has faculties of law, science and medicine; it had 318 students in 1902-1903. It contains an important museum of Etruscan and Roman antiquities. Three miles to the S.S. E. the Etruscan necropolis of the ancient city was discovered in 1870. The large tomb of the Volumni (3rd century B.C.) hewn in the rock, with its carved cinerary urns, is interesting.

The ancient Perugia first appears in history as one of the twelve confederate cities of Etruria. It is first mentioned in the account of the war of 310 or 300 B.C. between the Etruscans and the Romans. It took, however, an important part in the rebellion of 205, and was reduced, with Vulsci and Arretium, to seek for peace in the following year. In 216 and 205 it assisted Rome in the Hannibalic war, but afterwards it is not mentioned until 41-40 B.C., when L. Antonius took refuge there, and was reduced by Octavian after a long siege. A number of lead bullets used by slingers have been found in and around the city (Corpus inscr. lat. xii. 1212). The city was burnt, we are told, with the exception of the temples of Vulcan and Juno—the massive Etruscan terrace-walls, naturally, can hardly have suffered at all—and the town, with the territory for a mile round, was allowed to be occupied by whoever chose. It must have been rebuilt almost at once, for several bases exist, inscribed "MADMI (i.e. Marcus Audunius Maurus) Perutio restituit;" but, as we have seen, it did not become a colony until A.D. 251-253. It is hardly mentioned except by the geographers until the middle of the 6th century, when it was captured by Totila after a long siege. In the Lombard period it is spoken of as one of the principal cities of Tuscia. In the 9th century, with the consent of Charles the Great and Louis the Pious, it passed under the popes; but for many centuries the city continued to maintain an independent life, warring against many of the neighboring lands and cities—Foligno, Assisi, Spoletto, Montepulciano, &c. It remained true for the most part to the Guelfs. On various occasions the popes found asylum within its walls, and it was the meeting-place of the conclaves which elected Honorius II. (1124), Honorius IV. (1285), Celestine V. (1294), and Clement V. (1305). But Perugia had no mind simply to subserve the papal interests. At the time of Rienzi's unfortunate enterprise it sent ten ambassadors to pay him honour; and, when papal legates sought to coerce it by foreign soldiers, or to exact contributions, they met with vigorous resistance. In the 15th century power was at last concentrated in the Baglioni family, though, they had no legal position, defied all other authority. Gian Paolo Baglioni was lured to Rome in 1520 and beheaded by Leo X.; and in 1534 Rodolfo, who had slain a papal legate, was defeated by Pier Luigi Farnese, and the city, and captured and plundered by his soldiers, was deprived of its privileges. The citadel was begun six years later "ad coerendam Perusinorum audaciam." In 1707 Perugia was occupied by the French; in 1832, 1835, and 1854 it was visited by earthquakes; in May 1849 it was seized by the Austrians; and, after a futile insurrection in 1859, it was finally united, along with the rest of Umbria, to Piedmont, in 1860.

PERUGINO, PIETRO (1446-1524), whose correct family name was VANNUCCI, Italian painter, was born in 1446 at Città della Pieve in Umbria, and belongs to the Umbrian school of painting. The name of Perugino came to him from Perugia, the chief city of the neighbourhood. Pietro was one of several children born to Cristoforo Vannucci, a member of a respectable family settled at Città della Pieve. Though respectable, they seem to have been poor, or else, for some reason or other, to have left Pietro un cared for at the opening of his career. Before he had completed his ninth year the boy was articled to a master, a painter at Perugia. Who this may have been is very uncertain; the painter is spoken of as wholly mediocre, but sympathetic for the great things in his art. Benedetto Bonfigli is generally surmised; if he is rejected as being above mediocrite, either Fiorenzo di Lorenzo or Niccolò da Foligno may possibly have been the man. Pietro painted a little at Arezzo; thence he went to the headquarters of art, Florence, and frequented the famous Brancacci Chapel in the church of the Carmine. It appears to be sufficiently established that he studied in the atelier of Andrea del Verrocchio, where Leonardo da Vinci was also a pupil. He may have learned perspective, in which he particularly excelled for that period of art, from Piero de' Franceschi. The date of this first Florentine sojourn is by no means settled; some authorities incline to make it as early as 1470, while others, with perhaps better reason, postpone it till 1475. Pietro at this time was extremely poor; he had no bed, but slept on a chest for many months, and, bent upon making his way, resolutely denied himself every creature comfort.

Gradually Perugino rose into notice, and became famous not only throughout Italy but even beyond. He was one of the earliest Italian painters to practise oil-painting, in which he evinced a depth and smoothness of tint, which elicited much remark; and in perspective he applied the novel rule of two centres of vision. Some of his early works were extensive frescoes for the Ingesati fathers in their convent, which was destroyed not many years afterwards in the course of the siege of Florence; he produced for them also many cartoons, which they executed with an elegant effect in stained glass. Though greedy for gain, his integrity was proof against temptation; and an amusing anecdote has survived of how the prior of the Ingesati doled out to him the costly colour of ultramarine, and how Perugino, constantly washing his brushes, obtained a surreptitious hoard of the pigment, which he finally restored to the prior to shame his stingy suspiciousness. A good specimen of his early style in tempera is the circular picture in the Louvre of the "Virgin and Child enthroned between Saints."

Perugino returned from Florence to Perugia, and thence, towards 1483, he went to Rome. The painting of that part of the Sixtine Chapel which is now immortalized by Michelangelo's "Last Judgment" was assigned to him by the pope; he covered it with frescoes of the "Assumption," the "Nativity," and "Moses in the Bulrushes." These works were ruthlessly destroyed to make a space for his successor's more colossal genius, but other works by Perugino still remain in the Sixtine Chapel; "Moses and Zipporah" (often attributed to Signorelli), the "Baptism of Christ," and "Christ giving the Keys to Peter." Pinturicchio accompanied the greater Umbrian to Rome, and was made his partner, receiving a third of the profits; he may probably have done some of the Zipporah subject.

Pietro, now aged forty, must have left Rome after the completion of the Sixtine paintings in 1486, and in the autumn of that year he was in Florence. Here he figures by no means advantageously in a criminal court. In July 1450 he and another Perugian painter named Aulista di Angelo were convicted, on their own confession, of having in December waylaid with staves some one (the name does not appear) in the street near S. Pietro Maggiore. Pietro limited himself, in intention, to assault and battery, but Aulista had made up his mind for murder. The minor and more illustrious culprit was fined ten gold florins, and the major one exiled for life.

Between 1486 and 1490 Perugino resided chiefly in Florence, making one journey to Rome and several to Perugia. He was in many other parts of Italy from time to time. He had a regular shop in Florence, received a great number of commissions, and continued developing his practice as an oil-painter, his
system of superposed layers of colour being essentially the same as that of the Van Eycks. One of his most celebrated pictures, the “Pieta” in the Pitti Gallery, belongs to the year 1505. From about 1508 he became increasingly keen after money, frequently repeating his groups from picture to picture, and leaving much of his work to journeymen. In 1511 the gild of the cambio (money-changers or bankers) of Perugia asked him to undertake the decoration of their audience-hall, and he accepted the invitation. This extensive scheme of work, which may have been finished within the year 1520, comprised the painting of the vault with the seven planets and the signs of the zodiac (Perugino doing the designs and his pupils most probably the executive work) and the representation on the walls of two sacred subjects—the “Nativity” and “Transfiguration”—the Eternal Father, the four virtues of Justice, Prudence, Temperance and Fortitude, Cato as the emblem of wisdom, and (in life size) numerous figures of classic worthies, prophets and sibyls. On the mid-pilaster of the hall Perugino placed his own portrait in bust-form. It is probable that Raphael, who in boyhood, towards 1506, had been placed by his uncles under the tuition of Perugino, bore and in the work of the vaulting. It may have been about this time (though some accounts date the event a few years later) that Vannucci married a young and beautiful wife, the object of his fond affection; he loved to see her handsomely dressed, and would often deck her out with his own hands. He was made one of the priors of Perugia in 1511.

While Perugino, though by no means stationary or unprogressive as an executive artist, was working contentedly upon the old lines and carrying out the ancient conceptions, a mighty wave of new art flooded Florence with its rush and Italy with its rumour. Michelangelo, twenty-five years of age in 1520, following after and distancing Leonardo da Vinci, was opening men’s eyes and minds to possibilities of achievement as yet unsurmised. Vannucci in Perugia heard Buonarroti broiled abroad, and was impatient to see with his own eyes what the stir was all about. In 1504 he allowed his apprentices and assistants to disperse, and returned to Florence. Though not openly detracting, he viewed with jealousy and some grudging the advances made by Michelangelo; and Michelangelo on his part replied, with the intolerance which pertains to superiority, to the faint praise or covert dispraise of his senior and junior in the art. On one occasion, in company, he told Perugino to his face that he was “a bungler in art” (goffo nell’arte). Vanucci brought, with equal indiscretion and ill success, an action for defamation of character. Put on his mettle by this mortifying transaction, he determined to show what he could do, and he produced the chef-d’œuvre of the “Madonna and Saints” for the Certosa of Pavia. The constituent parts of this noble work have now been sunned. The only portion which remains in the Certosa is a figure of God the Father with cherubim. An “Annunciation” has disappeared from cognisance; three compartments—the Virgin adoring the infant Christ, St Michael, and St Raphael with Tobias—are among the choicer treasures of the National Gallery, London. The current story that Raphael bore a hand in the work is not likely to be true. This was suggested in 1595 by an “Assumption” in the Cappella di Raffaello, in the church of the Servi in Florence. The painting may have been executed chiefly by a pupil, and was at any rate a failure: it was much decired; Perugino lost his scholars; and towards 1516 he once more and finally abandoned Florence, going to Perugia, and thence in a year or two to Rome.

Pope Julius II. had summoned Perugino to paint the Stanza in the Vatican, now called that of the Incendio del Borgo; but he soon preferred a younger competitor, that very Raphael who had been trained by the aged master of Perugia; and Vannucci, after painting the ceiling with figures of God the Father in different glories, in five medallion-subjects, found his occupation gone; he retired from Rome, and was once more in Perugia from 1512. Among his latest works one of the best is the extensive altar-piece (painted between 1512 and 1517) of S. Agostino in Perugia; the component parts of it are now dispersed in various galleries.

Perugino’s last frescoes were painted for the monastery of S. Agnese in Perugia, and in 1523 for the church of Castello di Fortignano hard by. Both series have disappeared from their places, the second being now in the Victoria and Albert Museum. He was still at Fortignano in 1524 when the plague broke out, and he died. He was buried in unconsecrated ground in a field, the precise spot now unknown. The reason for so obscure and unwonted a mode of burial has been discussed, and religious scepticism on the painter’s own part has been assigned as the cause; the fact, however, appears to be that, on the sudden and widespread outbreak of the plague, the panic-struck local authorities ordained that all victims of the disorder should be at once interred without any waiting for religious rites. This leads us to speak of Perugino’s opinions on religion. Vasari is our chief, but not our sole, authority for saying that Vannucci had very little religion, and was an open and obdurate disbeliever in the immortality of the soul. For a reader of the present day it is easier than it was for Vasari to suppose that Perugino may have been a materialist, and yet just as good and laudable a man as his orthodox Catholic neighbours or brother-artists; and he will be relieved to know that, in the general immorality in which all is throughout Christian, Catholic, devotional, and even pietistic, and the character of an anti-Christian con- temner of the doctrine of immortality. It is difficult to reconcile this discrepancy, and certainly not a little difficult also to suppose that Vasari was totally mistaken in his assertion; he was born twenty years before Perugino’s death, and much has been talked with scores of people to whom the Umbrian painter had been well known. We have to remark that Perugino in 1504 painted his own portrait, now in the Uffizi Gallery of Florence, and into this he introduced a scroll lettered “Timete Deum.” That an open disbeliever should inscribe himself with “Timete Deum” seems odd. The portrait in question shows a plump face, with small dark eyes, a short but well-cut nose, and sensitive lips; the neck is thick, the hair bushy and frizzled, and the general air imposing. The later portrait in the Cambio of Perugia shows the same face with traces of added years. Perugino possessed considerable property, leaving three sons.

Among the very numerous works of Perugino a few not already named require mention. Towards 1500 he painted the “Cruci-fxion,” in S. Maria Maddalena dei Pazzi, Florence. The attribution to him of the picture of the marriage of Joseph and the Virgin Mary (the “Sposalizio”) now in the museum of Caen, which served individuated fresco of the original, to a great extent, by another more famous “Sposalizio” which was painted by Raphael in 1504, and which forms a leading attraction of the Brera Gallery in Milan, is now questioned, and it is assigned to L. Spagna. A vastly finer work of Perugino’s is the “Cristo dei Servi,” which was painted a little earlier for S. Pietro of Perugia, has for years past been in the museum of Lyons; the other portions of the same altar-piece are dispersed in other galleries. In the chapel of the Disciplinati di Città della Pieve is an “Adoration of the Magi,” a square of 21 ft. containing about thirty life-sized figures; this was executed, with scarcely credible celerity, from the 1st to the 25th of March (or thereabouts) in 1505, and must no doubt be in great part the work of Vannucci’s pupils. In 1507, when the master’s work had for years been progressing so consistently as to give him at the end of the year generally weak, he produced, nevertheless, one of his best pictures—the “Virgin between St Jerome and St Francis,” now in the Palazzo Penna. In S. Onofrio of Florence is much a lauded and much-maligned fresco of the “Last Supper,” a careful and blandly correct but not inspired work; it has been ascribed to Perugino by some connoisseurs, by others to Raphael; it may more probably be by some different pupil of the Umbrian master.

PERUKE, an artificial head of hair, a wig. The word is from Fr. Perruque, an adaptation of Ital. perouca or parucca. This is usually taken to be from Ital. pelo, hair; Lat. pilus. Span. peluca, wig, and Sardinian pellica, lock or tuft of hair, support this view. In the 17th century the English French which the French word took, such as Perruk, or Perug, were corrupted into perwuye, and thence into perwyke, perwyg, and finally "perwige," which again was shortened into "wig," the
common term for all types of artificial heads of hair. Periwig is sometimes confined to the heavy full-bottomed wigs worn from the reign of Charles II. to the introduction of the light, tailed wig of the 18th century.

PERUZZI, BALDASSARE (1481-1536), Italian architect and painter of the Roman school, was born at Anciano, in the diocese of Volterra, and passed his early life at Siena, where his father resided. While quite young Peruzzi went to Rome, and there studied architecture and painting; in the latter he was at first a follower of Perugino. The choir frescoes in Sant' Onofrio on the Janiculan Hill, usually attributed to Pinturicchio, are by his hand. One of the first works which brought renown to the young architect was the villa on the banks of the Tiber, now known as the Villa Medici, formerly built for the Sienese Agostino Chigi, a wealthy banker. This villa, like all Peruzzi's works, is remarkable for its graceful design and the delicacy of its detail. It is best known for the frescoes painted there by Raphael and his pupils to illustrate the stories of Psyche and Galatea. Of the loggie has frescoes by Peruzzi's own hand—the story of Medusa. On account of his success Peruzzi was appointed by Leo X. in 1520 architect to St Peter's at a salary of 250 scudi; his design for its completion was not, however, carried out. During the sack of Rome in 1527 Peruzzi barely escaped with his life, on condition of his painting the portrait of Constable de Bourbon, who had been killed during the siege (see VASARI). From Rome he escaped to Siena, where he worked in great designs for its defence, a great part of which still exist. Soon afterwards he returned to Rome, where he made designs for a palace for the Orsini family, and built the palaces Massimi and Viodini, as well as others in the south of Italy. He died in 1536, and was buried by the side of Raphael in the Pantheon.

Peruzzi was an eager student of mathematics and was also a fair classical scholar. Like many of the great artists of his time, he was remarkable for the varied extent of his knowledge and skill. A most able architect, a fair painter, and a scientific engineer, he also practised minor arts, such as stucco-work in relief, sgraffito, and the decorative painted arabesques which the influence of Raphael did so much to bring into use. His best existing works in fresco are in the Castel di Belcaro and the church of Fontegiusta in Siena. For Siena Cathedral he also designed a magnificent wooden organ-case, painted and gilt, rich with carved arabesques in friezes and pilasters; he also designed the high altar and the Cappella del Battista.

His chief pupil was the architect Serlio, who, in his work on architecture, gratefully acknowledges the great debt he owed to Peruzzi's instruction. The English National Gallery possesses an interesting drawing by his hand. The subject is the "Adoration of the Magi," and it is of special value, because the heads of the three kings are portraits of Michelangelo, Raphael, and Titian. The Uffizi and the library at Siena contain a number of Peruzzi's designs and drawings, many of which are now of priceless value, as they show ancient buildings which have been destroyed since the 16th century.

PERVIGLIIUM 1 VENERIS, the Vigil of Venus, a short Latin poem. The author, date, and place of composition are unknown. The poem probably belongs to the 2nd or 3rd century A.D. An article signed by L. Raquettius in the Classical Review (May 1905) assigns it to Sidonius Apollinaris (5th cent.). It was written probably in early spring on the eve of a three-nights' festival of Venus (probably April 1-3). It describes in a poetic language the annual awakening of the vegetable kingdom; and it is compiled of a prelude. It consists of ninety-three verses in trochaic septenarii, and is divided into strophes of unequal length by the refrain: "Cras amet qui nuncum amavit; quique amavit cras amet."

1 Perviglum was the term for a nocturnal festival in honour of some divinity, especially Bona Dea.

Editio princeps (1577); modern editions by F. Bücheler (1859), A. Riese, in Anthologia Latina (1869), E. Bährns in Underte latinske Gedichte (1877); S. G. Owen (with Catullus, 1893). There are translations into English verse by Thomas Stanley (1661) and Thomas Parrnell, author of The Hermit; on the text see J. W. Mackail in Journal of Philology (1888), vol. xvii.

PESARO (anc. Pissaurum, q.v.), a city and seaport of the Marches, Italy, the capital of the province of Pesaro and Urbino, situated on the coast of the Adriatic 37 m. N.W. of Ancona by rail, on the right bank of the Foglia, the ancient Pissaurus. The ground on which it is built is only from 10 to 30 ft. above the sea, but it is surrounded by hills—on the E. by Monte Ardizo, on the W. by Monte Accio or San Bartolo, which derives of its names from the tradition that the Roman dramatist Terence was buried there. The town was afterwards built on the spot. Upon this hill stands the Villa Imperiale, the foundation stone of which was laid by the emperor Frederick III., built by the Sforza, and decorated with fine stucco ceilings and wall paintings and pavements of majolica plaques. A new palace was begun in 1550 by the Genga for Eleonora Gonzaga, but never finished. The city walls were in 1830 transformed into a public promenade. Besides the ancient cathedral of the Annunciation (restored since 1860) with a 14th-century mosaic pavement, there are a number of smaller churches, several with Gothic portals. One of these, the church of San Francesco, now used as a cathedral, contains the "Coronation of the Virgin" by Giovanni Bellini, the largest and most important of his works outside Venice. The most remarkable building is the palace originally erected in 1455-1465 by the Dalmatian architect Luciano da Laurana for the Sforza, and restored by Francesco Maria della Rovere in the 16th century, the Rossini theatre (opened in 1818), the fortress of Rocca Costanzia (built by Costanzo Sforza in 1474, Laurana being the architect), and the large lunatic asylum. The composer Gioacchino Rossini, who was a native of Pesaro, left all his fortune to found a musical lyceum in the city, and his statue by Marochetti (1864) stands near the railway station. The Olivieri library (established by the antiquary of that name, author of Marmora piaurensia, &c.) contains about 14,000 volumes, MSS. of Tasso, &c., inscriptions and various antiquities, and a very fine collection of majolica (one of the best in Italy) from the old Urbino and other manufactories. The Museo Mosca, left by its owner to the town, contains important collections of faience, furniture, &c. Among the industries of Pesaro are the growing, spinning and weaving of silk, tanning, iron-foundling, and the manufacture of glass and pottery. It is also the centre of a rich agricultural district. The harbour is of no great importance, but there is a small export trade in wine, olives, silk and glass. Pop. (1901), 14,768 (town); 24,823 (commune).

 Destroyed by Vitiges the Goth, the town was restored and strengthened by Belisarius, and afterwards along with Ancona, Fano, Senigallia, and Rimini formed the Pentapolis Maritima. In the course of the 13th century Pesaro was sometimes under the government of the popes, sometimes under the emperors; but the Malatesta family, which first took root in the city about 1285, gradually became the real masters of the place. In 1445 they sold their rights to Francesco Sforza; and in 1512, through the influence of Julius II., the Sforza were supplanted by his nephew Francesco Maria, duke of Urbino. Leo X. took the city away from Francesco and gave it to Lorenzo de' Medici; but on Lorenzo's death Francesco was restored and Pesaro became the ordinary residence of the dukes of Urbino till the death of Francesco Maria II. in 1631, when it reverted to the States of the Church. It has formed part of the present kingdom of Italy since 1860. Terenzio Mamiani della Rovere, poet and statesman, was born at Pesaro in 1570.

PESCADORES (i.e. fisheis), a group of islands (called by the Japanese Hōkō to or Hōkō Gunto) lying 30 m. west of Formosa, from which they are separated by the Pescadores Channel, about the tropic of Cancer. The islands number 48 (21 inhabited), have a coast-line of 98-67 miles, a total area of 85-50 sq. m., and a population of about 55,000, principally Chinese. Flat and with unproductive soil, they are swept during one
half of the year by violent N.E. winds, and also lie full in the path of the numerous typhoons that rush up the Strait of Formosa. Meteorological observations taken by the Japanese during a period of three years show that the average number of stormy days is 237. The anchorage is at Makō-Makunouchi on the principal island of Penghu. The chief industry is fishing (whence the old Spanish name which has come into general use) and dried fish are exported.

**PESCARA.**

Fernando Francesco Davales, Marquis of (1489-1525), Italian condottiere, was born at Naples, his family being of Spanish origin. Rodrigo (Ruy) Lopez Davales, his great-grandfather, a noble of Toledo, who had taken an active part in the civil wars of Castile in the reign of John II. (1407-1454), had been driven into exile, and died at Valencia. Iñigo (Ignattius), his son, entered the service of Alphonso of Aragon and Naples, followed his master to Italy, and there, making an advantageous marriage with a lady of the family of Aquino, was created marquis of Pescara. His son Alphonso, who succeeded him in the marquisate, married a lady of the Sicilian branch of the Spanish family of Cardona, and when he was treacherously killed, during a French invasion of Naples, his widow struck in the rear of the Spaniards, for which she is called the wife of the son of the condottiere. On the death of the wife of the son of the condottiere, the age of six the boy was betrothed to Vittoria Colonna (q.v.), daughter of the general Fabrizio Colonna, and the marriage was celebrated in 1509. His position as a noble of the Aragonese party in Naples made it incumbent on him to support Ferdinand the Catholic in his Italian wars. In 1512 he commanded a body of light cavalry at the battle of Ravenna, where he was wounded and taken prisoner by the French. Thanks to the intervention of one of the foremost of the French generals, the Italian J. J. Trivulzio, who was his connexion by marriage, he was allowed to ransom himself for 6000 ducats. He commanded the Spanish infantry at the battle of La Morta, or Vicenza, on the 7th of October, 1513. It was on this occasion that he called his men before the charge to take care to step on him before the enemy did if he fell. From the battle of Vicenza in 1513, down to the battle of La Bicocca on the 29th of April, 1522, he continued to serve in command of the Spanish and as the colleague rather than the subordinate of Prosper Colonna. It was only by the accident of his birth at Naples that Pescara was an Italian. He considered himself a Spaniard, spoke Spanish at all times, even to his wife, and was always surrounded by Spanish soldiers and officers. His opinion of the Italians as fighting men was unfavourable and was openly expressed. After the battle of La Bicocca Charles V. appointed Prosper Colonna commander-in-chief. Pescara, who considered himself aggrieved, made a journey to Valladolid in Spain, where the emperor then was, to state his own claims. Charles V., with whom he had long and confidential interviews, persuaded him to submit for the time to the superiority of Colonna. But in these meetings he gained the confidence of Charles V. His Spanish descent and sympathies marked him out as a safer commander of the imperial troops in Italy than an Italian could have been. When Francis I. invaded Italy in 1524, Pescara was appointed as lieutenant of the emperor to repel the invasion. The difficulties of his position were very great, for there was much discontent in the army, which was very ill paid. The tenacity, patience and tact of Pescara triumphed over all obstacles. His influence over the veteran Spanish troops and the German mercenaries kept them loyal during the long siege of Pavia. On the 24th of February, 1525, he defeated and took prisoner Francis I. by a brilliant attack. Pescara's plan was remarkable for its audacity and for the skill he showed in destroying the superior French heavy cavalry by assailing them in flank with a mixed force of harquebusiers and light horse. It was believed that he was dissatisfied with the treatment he had received from the emperor; and Girolamo Morone, secretary to the Duke of Milan, approached him with a scheme for expelling French, Spanish and Germans alike from Italy, and for gaining a throne for himself. Pescara may have listened to the tempter, but in act he was loyal. He reported the offer to Charles V. and put Morone into prison. His health however had begun to give way under the strain of wounds and exposure; and he died at Milan on the 4th of November, 1525. Pescara had no children; his title descended to his cousin the marquis del Vasto, also a distinguished imperial general.

**PESCHIERA SUL GARDA.**

A fortress of Venetia, Italy, in the province of Verona, on an island in the Mincio at its outlet from the lake of Garda, 77 m. by rail E. of Milan. It was one of the famous fortresses of the Quadrilateral, the chief bulwark of the Austrian rule in Italy until 1866 (Mantua, Legnago and Verona being the other three) and has played a prominent part in all the campaigns conducted in north Italy, more especially during the Napoleonic wars. It was taken by the Piedmontese from the Austrians, after a gallant defence by General Rath lasting six weeks, on the 30th of May, 1848, and since that date has been in Italian hands.

**PESCIA.**

A town of Tuscany, Italy, in the province of Lucca, from which it is 15 m. E.-N. by rail, 203 ft. above sea-level. Pop. (1901), 12,400 (town); 18,000 (commune). The cathedral, restored in 1605, contains the fine chapel of the Turini family, built for Baldassare Turini (d. 1540) by Giuliano di Baccio di Florence, with his tomb by Raffaello da Montelupo. The town also has some buildings by Lazzaro Buggiani, the pupil and adoptive son of Brunelleschi. It has silk and paper manufactures.

**PESSETA,** a silver coin and unit of value, the Spanish equivalent of the French, Belgian and Swiss franc, the Italian lira and the Greek drachma in the Latin monetary union. The peso (Lat. pensum, weight), of which peseta is a diminutive, was a Spanish coin of gold, peso de oro, or silver, peso de plata, once current in Spain and her colonies, and now the name of a silver coin of many South American states. The peso is also the name of the Mexican dollar.

**PESHAWAR.**

A city of British India, the capital of the North-West Frontier Province, giving its name to a district. The city is situated near the left bank of the river Bara, 11 m. from Jamrud at the entrance of the Khyber Pass, the railway station being 1588 m. north-west of Calcutta; pop. (1901), 95,147. Two miles west of the native city are the cantonments, forming the principal military station of the North-West Frontier Province. Peshawar lies within a horseshoe ring of hills on the edge of the mountain barrier which separates India from Afghanistan, and through it have passed nearly all the invaders from the north. The native quarter is a huddle of flat-roofed houses within mud walls, crowded along narrow, crooked alleys; there is but one fairly wide street of shops. Here for many centuries the Povindahs, or Afghan travelling merchants, have brought their caravans from Kabul, Bokhara and Samarkand every autumn. They
brings horses, wool, woollen stuffs, silks, dyes, gold-thread, fruits, precious stones, carpets and poshtins (sheepskin clothing), fighting and buying their way to the British border where, leaving their arms, they are free to wander at will to Delhi, Agra and Calcutta. The chief speciality of Peshawar consists of bright-coloured scarves called lungis; wax-cloth and ornamental needle-work are also local products, as well as knives and small arms.

The district of Peshawar has an area of 2611 sq. m.; pop. (1901), 788,707, showing an increase of 10-8% in the decade. Except on the south-east, where the Indus flows, it is encircled by mountains which are inhabited by the Mohmand, Uman Khel and Afridi tribes. The plain consists of alluvial deposits of silt and gravel. The district is naturally fertile and well watered, and is irrigated by the Swat River, canal. The principal crops are wheat, barley, maize, millets and oil-seeds, with a little cotton and sugar-cane. Peshawar also produces a fine variety of rice, known as "Bara rice," after the river which irrigates it. The North-Western railway crosses the district from Attok, and has been extended from Peshawar city to Jamrud for military purposes. The district is chiefly inhabited by Pathans; there are some Hindus engaged in trade as bankers, merchants and shop-keepers.

In early times the district of Peshawar seems to have had an essentially Indian population, for it was not till the 15th century that its present Pathan inhabitants occupied it. Under the name of Gandhara it was a centre of Buddhism, and especially Graeco-Buddhism. Rock-edicts of Asoka still exist at two places; and a stupa excavated in 1909 was found to contain an inscription of Kanishka, as well as relics believed to be those of Buddha himself. The last of the Indian Buddhist kings was conquered by Mahmud of Ghazni in 1009. The Mogul emperors always found difficulty in maintaining their authority over the Afghan border tribes, who finally established their independence during the reign of Aurangzeb. Peshawar was a favourite residence of the Afghan dynasty founded by Ahmad Shah Durrani, and here Mountstuart Elphinstone came as ambassador to Shah Shujah in 1809. A few years later Ranjit Singh crossed the Indus, and after much hard fighting Sikh authority was firmly established under General Avitabile in 1834. In 1848 the whole of the Punjab passed to the British. During the Mutiny, after the sepoys' regiments had been disarmed, Peshawar was a source of strength rather than of danger, though Sir John Lawrence did at one time contemplate the necessity of surrendering it to the Afghans, in order to preserve the rest of Northern India.

PESHIN, or Peshin, a district of Baluchistan. Area 2717 sq. m. Pop. (1901), 50,200. It consists of a large plain surrounded on three sides by hills, which formerly belonged to Afghanistan but was ceded to the British by the treaty of Gandamak in 1879. This plain is of considerable strategic importance, as it forms the focus of a great number of routes leading from Sind and the Punjab frontier districts to Kandahar, and is intersected by the Sind-Peshin railway. The agricultural wealth of Peshin, and consequently its revenues, have increased greatly under British administration.

PESHTITO, or Peshtito (i.e. "simple"?), the standard version of the Bible in the Syriac language. It was long supposed to be the original Syriac version, but is now generally recognized as representing a revision made by Rabbula, bishop of Edessa, early in the 5th century, an attempt at standardizing the Syriac text such as Jerome had made for the Latin in his Vulgate. (See Bible.

PESHTWA (Persian for "leader," "guide"?), the title of the head of the Mahratta confederacy in India. Originally the peshwa was only prime minister, but afterwards he supplanted his master and became chief of the state, founded an hereditary dynasty, with the capital at Poona. The last peshwa, Baji Rao, came into collision with the British, and was dethroned in 1818. His adopted son, Nana Sahib, took a leading part in the Mutiny of 1857, in revenge for being deprived of what he considered his rights.

PESSEMIN (from Lat. pessimus, worst), a word of modern coinage,1 denoting an attitude of hopelessness towards life, a vague general opinion that pain and evil predominate in human affairs. It is the antithesis of "optimism," which denotes the view that on the whole there is a balance of good and pleasure, or at least that in the long run good will triumph. Between optimism and pessimism is the theory of "meliorism," according to which the world on the whole makes progress in goodness. The average man is pessimist or optimist not on theoretical grounds, but owing to the circumstances of his life, his material prosperity, his bodily health, his general temperament. Perhaps the most characteristic example of unsystematic pessimism is the language of Ecclesiastes, who concludes that "all is vanity."

Pessimism and optimism have, however, been expressed in systematic philosophical forms, a brief summary only of which need here be given. Such systems have been elaborated chiefly by modern thinkers, but the germs of the ideas are found widely spread in the older Oriental philosophies and in pre-Christian European thought. Generally speaking, pessimism may be found in all pantheistic and materialistic systems. It is important, however, to point out an essential distinction. The thinker who sees man confronted by the infinite non-moral universe is inevitably predominating over the finite powers of man by his modern Christian theologian or to the evolutionist as a hopeless pessimist, and yet may himself have concluded that, though the future holds out no prospect save that of annihilation, man may yet by prudence and care enjoy a considerable measure of happiness. Pessimism, therefore, depends upon the individual point of view, and the term is frequently used merely in a condemnatory sense by hostile critics. The attitude of a man who denies the doctrine of immortality and rejoices in the denial is not strictly pessimistic. A Christian again may be pessimistic about the present; he must logically be optimistic about the future—a teleological view of the universe implies optimism on the whole; the agnostic may be indifferent to, or pessimistic, regarding the future, while exceedingly satisfied with life as he finds it.

This complex view of life is exemplified by Plato, whose general theory of idealism is entirely optimistic. In analysing the world of phenomena he necessarily takes a pessimistic view because phenomena are merely imitations more or less removed from reality, i.e. from the good. Yet the idealistic postulate of a summum bonum is in result optimistic; and this view predominated among the Stoics and the Neoplatonists. The Epicureans, on the other hand, were empirical pessimists. Man is able to derive a measure of enjoyment from life in spite of the non-existence of the orthodox gods; yet this enjoyment is on the whole negative, the avoidance of pain. A similar view is that of the ancient sceptics.

Oriental pessimism, at least as understood by Europeans, is best exemplified in Buddhism, which finds in human life sorrow and pain. But all pain and sorrow are incidental to the human being in his individual capacity. He who will cast aside the "Bonds," the "Intoxications," the "Hindrances," and tread the Noble Eightfold Path (see Buddhism) which leads to Nirvana, will attain the ideal, the "Fruit of Arhatship," which is described in terms of glowing praise in the Pali hymns. This, the original doctrine of the Buddha, though not adopted in the full sense by all his followers, is in fact at least as optimistic as any optimism of the West. To call it "pessimism" is merely to apply it to a characteristically Western principle according to which happiness is impossible without personality. The true Buddhist on the contrary looks forward with enthusiasm to this absorption into eternal bliss.

In Europe on the whole the so-called pessimistic attitude was commoner in the Teutonic north than in the Mediterranean basin. But even here the hopefulness as regards a future life, in which the inequalities of the present would be rectified, compensated for the gloomy fatalism with which the present was 1 The earliest example given in the New English Dictionary is in S. T. Coleridge's Letters (1794).
regarded. The advent of Christianity, with its categorical assertion of future happiness for the good, to a large extent did away with pessimism in the true sense. In Leibnitz we find a philosophic or religious optimism, which saw in the universe the perfect work of a God who from all possibilities selected the best. Kant, though pessimistic as regards the actual man, is optimistic regarding his moral capacity. To Hegel similarly the world, though evil at any moment, progresses by conflict and suffering toward the good.

Passing over the Italian Leopardi we may notice two leading modern pessimists, Schopenhauer and von Hartmann. Schopenhauer emphasizes the pessimistic side of Hegel's thought. The universe is merely blind Will, not thought; this Will is irrational, purposeless and therefore unhappy. The whole being a picture of the Will is therefore similarly unhappy. Desire is a state of unhappiness, and the satisfaction of desire is therefore merely the removal of pain. Von Hartmann's doctrine of the Unconscious is in many respects similar to Schopenhauer's doctrine of the Will. The Unconscious which combines Will and Reason is, however, primarily Will. The workings of this Will are irrational primarily, but, as in its evolution it becomes more rationalized and understands the whole meaning of the Welt schmerz, it ultimately reaches the point at which the desire for existence is gone. This choice of final nothingness differs from that of Schopenhauer in being collective and not individual. The pessimism of Schopenhauer and Hartmann does not, however, exclude a certain ultimate mysticism, which bears some analogy to that of Buddhism.

Pessimism is naturally connected with materialist, optimism with idealist, views of life. The theories of the modern evolutionist school, however, have introduced into materialistic theory a new optimistic note in doctrines such as that of the survival of the fittest. Such doctrines regard the progress of humanity as on the whole tending to the greater perfection, and are markedly optimistic in contrast with earlier theories that progressive differentiation is synonymous with progressive decay. Similarly the cynical contempt which Nietzsche shows for morality and the conventional virtues is counterbalanced by the theory of the Übermensch, the highest type of manhood which by struggle has escaped from the ordinary weaknesses of normal humanity.

See James Sully, Pessimism: A History and a Criticism (1877); Carus, Thrusts and Parries: The Natural History of Negation (1886); Tullioch, Modern Theories on Philosophy and Religion (1884); William James, The Will to Believe; Dühring, Der Wert des Lebens (1865); Meyer, Weltend und Welt schmerz (1872); E. H. Hare, P. F. (1878); Paulsen, Sophien, Hamlet, Mephisto phelus (1890); Kowa lewski, Studien zur Psychologie des P. (1904).

PESSINUS (Πεσίνος, Πέσινος), an ancient city of Galatia in Asia Minor, situated on the lowest southern slope of Mt. Dindymus, on the left bank of the river Sangarios, not far from its source. The ruins, discovered by Texier, lie round the village of Bara-Hissar, 8 or 9 m. S.E. of Sivri-Hissar. They include a theatre in partial preservation, but they have been mostly carried off to Sivri-Hissar, which is largely built out of them. Originally a Phrygian city, probably on the Persian "Royal Road," it became the capital of the Gallic tribe Tolistobogii and the chief commercial city of the district. It contained the most ancient sanctuary of the mother of the gods (Cybele), who here was worshipped by Aglabus, and was associated with the god Attis, as elsewhere with Sabazius, &c. Her priests were also princes, who bore rule not only in the city (the coinage of which, beginning about 100 B.C., was for long issued by them) but also in the country round, deriving a large revenue from the temple estates; but in the time of Strabo (a.d. 15–20) their privileges were much diminished. The high-priest always bore the god's name Attis. In the crisis of the second Punic War (203 B.C.), when the Romans lost faith in the efficacy of their own religion to save the state, the Senate, in compliance with an oracle in the Sibylline books to the effect that the foreign books could be driven from Italy if the Idaean Mother (Cybele) were brought from Pessinus to Rome, sent ambassadors to the town, who obtained the sacred stone which was the symbol of the goddess and brought it to Rome, where the worship of Cybele was established. But the goddess continued to be worshipped in her old home; her priests, the Galli, went out to welcome Manlius on his march in 189 B.C., which shows that the town was not yet in the hands of the Tolistobogii. Soon after this a splendid new temple of the goddess was built by the Pergamene kings. Some time before 164 B.C. Pessinus fell into the power of the Gauls, and the membership of the priestly college was then equally divided between the Gauls and the old priestly families. Like Ancyra and Tavium, Pessinus was Romanized first and Hellenized afterwards. Only about 1 d. ad. 165 did Hellenic ways and modes of thought begin to be assumed; before that we find a deep substratum of Celtic feeling and ways, on which Roman elements had been superimposed without filtering through a Hellenic medium. Christianity was introduced late; it cannot be traced before the 4th century. When Galatia was divided into two provinces (A.D. 386–395) Pessinus was made the capital of Galatia Secunda or Salutaris, and it became a metropolitan bishopric. After the 16th century it disappears from history, being supplanted, from the beginning of the period of Saracen invasion, by the impregnable fortress Justinianopolis (Sivri-Hissar), which became the capital and the residence of the bishop, thenceforward called "archbishop of Pessinus or of Justinianopolis." (J. G. C. A.)

PESTALOZZI, JOHANN HEINRICH (1746–1827), Swiss educational reformer, was born at Zürich on the 12th of January 1746. His father died when he was young, and he was brought up by his mother. At the university of Zürich he was associated with Lavater and the party of reform. His earliest years were spent in schemes for improving the condition of the people. The death of his friend Bluntschli turned him however from politics, and induced him to devote himself to education. He married at twenty-three and bought a piece of waste land at Neuholz in Aargau, where he attempted the cultivation of madder. Pestalozzi knew nothing of business, and the plan failed. Before this he had opened his farm-house as a school; but in 1780 he had to give this up also. His first book published at this time was The Evening Hours of a Hermit (1780), a series of aphorisms and reflections. This was followed by his masterpiece, Leonard and Gertrude (1781), an account of the gradual reformulation, first of a household, and then of a whole village, by the efforts of a good and devoted woman. It was read with avidity in Germany, and the name of Pestalozzi was rescued from obscurity. The French invasion of Switzerland in 1798 brought in his real heroic character. A number of children were left in Canton Unterwalden on the shores of the Lake of Lucerne, without parents, home, food or shelter. Pestalozzi collected a number of them into a deserted convent, and spent his energies in reclaiming them. During the winter he personally tended them with the utmost devotion, but in June 1799 the building was required by the French for a hospital, and his charges were dispersed. In 1801 Pestalozzi gave an exposition of his ideas on education in the book How Gertrude teaches her Children. His method is to proceed from the easier to the more difficult. To begin with observation, to pass from observation to consciousness, from consciousness to speech. Then come measuring, drawing, writing, numbers, and so reckoning. In 1790 he had been enabled to establish a school at Burgdorf, where he remained till 1804. In 1802, he went as deputy to Paris, and did his best to interest Napoleon in a scheme of national education; but the great master turned Pestalozzi himself out of the alphabet. In 1805 he removed to Yverdon on the Lake of Neuchâtel, and for twenty years worked steadily at his task. He was visited by all who took interest in education—Talleyrand, Capo d'Istria, and Mme de Staël. He was praised by Wilhelm von Humboldt and by Fichte. His pupils included Ramsauer, Delbrick, Blochmann, Carl Ritter, Fröbel and Zeller. About 1815 dissensions broke out among the teachers of the school, and Pestalozzi's last ten years were
Petalite—Peter, St.

Chequered by weariness and sorrow. In 1825 he retired to Neuhof, the home of his youth; and after writing the adventures of his last work, the Swan's Song, he died at Brugg on the 17th of February 1827. As he said himself, the real work of his life did not lie in Burgdorf or in Veydum. It lay in the principles of education which he practised, the development of his observation, the training of the whole man, the sympathetic application of the teacher to the taught, of which he left an example in his six months' labours at Stanz. He had the deepest effect on all branches of education, and his influence is still being exhausted.

Pestalozzi's complete works were published at Stuttgart in 1819-1826, and an edition by Seyfarth appeared at Berlin in 1831. Volumes on his life and teaching have been written by De Guignes (1890), Barnard (1862), Krist (1875) and Pinloche (1901).

PETALITE, a mineral species consisting of lithium aluminium silicate, LiAlSiO₄. The monoclinic crystals approach spodumene (q.v.) in form, which is also a lithium aluminium silicate with the formula LiAlSiO₄. This is a perfect cleavage parallel to the basal plane, and the mineral usually occurs in platy cleavage masses; on this account it was named, from Gr. πέταλον (a leaf). The hardness is 6½ and the specific gravity 2·4 (that of spodumene being 3·16). The mineral is colourless or occasionally reddish, varies from transparent to translucent, and has a vitreous lustre. It was discovered in 1800 as cleavage masses in an iron mine on the island of Utö in the Stockholm archipelago, where it is associated with lepidolite, tourmaline (rubellite and indicolite) and spodumene. A variety known as "castor" is found as transparent glassy crystals associated with polyl (q.v.) in cavities in the granite of Elba. (L. J. S.)

PETARD (Fr. pétard, pêter, to make a slight explosion), a device formerly used by military engineers for blowing in a gate or other barrier. It consisted of a small metal or wooden case, usually of sugar-loaf shape, containing a charge of powder and fired by a fuse.

PETAR, DIKYS (1583-1662), Jesuit scholar, better known as DIONYSIUS PETAVIUS, was born at Orleans on the 21st of August 1583. Educated at Paris University, he came under the influence of Isaac Scaliger, who directed his attention towards the obscure father of the Church. In 1603 he was appointed to a lectureship at the University of Bourges, but resigned his place two years later, in order to enter the Society of Jesus. For many years he was professor of divinity at the Collège de Clermont, the chief Jesuit establishment in Paris; there he died on the 11th of December 1652. He was one of the most brilliant scholars in a learned age. Carrying on and improving the chronologial labours of Scaliger, he published in 1627 an Opus de doctrina temporum, which has been often reprinted. An abridgment of this work, Rationarium temporum, was translated into French and English, and has been brought down in a modern reprint to the year 1849. But Petar's eminence chiefly rests on his vast, but unfinished, De theologica dogmatibus, the first systematic attempt ever made to treat the development of dogma from the earliest times. (See Turke.)

PETCHENEGS, or PETSCHINS, a barbarous people, probably of Turkish race, who at the end of the 9th century were driven from Europe into the lower Ural, and for about 300 years wandered about from the northern frontier of the East Roman Empire. (See Turks.)

Peter (Lat. Petrus from Gr. πέτρος, a rock, Ital. Pietro, Pio, Pier, Fr. Pierre, Span. Pedro, Ger. Peter, Russ. Петр), a masculine name, derived from the famous surname bestowed by Christ upon his apostle Simon ("Thou art Peter and upon this rock will I build my church," Matt. xiv. 17-19). The name has consequently been very popular in Christian countries. It is noteworthy, however, that, out of deference to the "prince of the apostles" and first bishop of Rome, the name has never been assumed by a pope. The biographies which follow are arranged in the order: (1) the apostle; (2) kings; (3) other eminent men.

Peter, St., the chief of the Twelve Apostles. He is known also by other names: (a) "Simon" (Σίμων) in Mark four times and Luke seven times. This use is only found in narrative before the story of the mission of the apostles: it is also found in speeches. Matthew once, Mark once and Luke twice. (b) "Simon who is called Peter" is found in Matthew twice and Acts four times. (c) "Simon Peter" is found in Matthew once, Luke once, John seventeen times (and perhaps also in 2 Peter i. 1, where the text varies between Simon and Symeon. (d) "Peter" is found in Matthew nineteen times, Mark eighteen times, Luke sixteen times, Acts fifty-one times, John fifteen times, Galatians twice, 1 Peter once. (e) "Cephas" is found in John once, Galatians four times, 1 Corinthians four times. (f) Symeon (Σύμεων) is found in Acts once. It appears that the apostle had two names, each existing in a double form—Greek and Hebrew, Symeon (Σύμεων) which was Graecized according to the sound into Simon, and Cephas (Σέφας) which was Graecized according to the meaning into Peter (Πέτρος). Symeon and Simon are both well-known names in Aramaic and Greek respectively, but Cephas and Peter are previously unknown. Symeon was no doubt his original Aramaic name, and the earliest gospel, Mark, which has some claim specially to reproduce Petrine tradition, is careful to employ Simon until the name Peter had been given, and not then to use it again. The Gospels agree in regarding Cephas or Peter as an additional name, which was given by Christ. But they differ as to the occasion. According to Mark iii. 13 sqq. it was given on the occasion of the mission of the Twelve. According to John i. 42 it was given at his first call. According to Matt. xvi. 13 sqq. it was given after the recognition of Jesus as Messiah at Caesarea Philippi. This last account is the only one which describes any circumstances (for a further discussion see § 3 (2) below).

According to the Gospels Peter was the son of John (Ἰωάννης, John i. 42, xxi. 15 sqq.) or Jonas (Ἰωάννης, Matt. xxvi. 17). According to Mark i. 29 he was a fisherman of Capernaum, but John i. 44 describes him and his brother Andrew as of Bethsaida. From Mark i. 30 he is seen to have been married, and 1 Cor. ix. 5 suggests (but another interpretation is possible) that his wife went with him on his missionary journeys. In 1 Pet. v. 13 Mark is referred to as his son, but this is usually interpreted of spiritual kinship. According to legend (Acta Neronis et Achillei, and Acta Philippi) he had a daughter Petronilla, but there is no reason for thinking that this is historical.

The Gospel narratives are unanimous in describing Peter as one of the chief disciples of Christ, and from the time of his call he seems to have been present at most of the chief incidents in the narrative. He formed together with the sons of Zebedee to some extent an inner circle within the Twelve, and this favoured group is specially mentioned as present on three occasions—the raising of the daughter of Jairus (Mark v. 22-43; Matt. ix. 32; Luke viii. 41-56); the transfiguration (Mark x. 2 sqq.; Matt. xvi. 28-29; Luke xxii. 28 sqq.; and the scene at the Garden of Gethsemane (Mark xiv. 32 sqq.; Matt. xxvi. 36 sqq.). He is also specially mentioned in connexion with his call (Matt. x. 2-20; Mat. iv. 18 sqq.; Luke v. 1 sqq.; John i. 40 sqq.; the healing of his wife's mother (Matt. i. 21 sqq.; Matt. viii. 14 sqq.; Luke iv. 38 sqq.); the mission of the Twelve Apostles (Mark iii. 13 sqq.; Matt. x. 1 sqq.; Luke vi. 12 sqq.); the storm on the Lake of Galilee (Mark iv. 34 sqq.; Matt. xiv. 22 sqq.; John vi. 16 sqq.); the Messianic recognition at Caesarea Philippi (Mark vii. 27 sqq.; Matt. xvi. 16 sqq.; Luke ix. 18 sqq.); the incident of the payment of tribute by the coin found in the fish caught by Peter (Matt. xvii. 25 sqq.) and with various questions leading to parables or their explanations (Mark xiii. 36 sqq.; Luke xii. 41; Matt. xviii. 21 sqq.; Mark x. 28; Matt. xix. 27; Luke xviii. 28). In the week of the Passion he appears in connexion with the incident of the withered fig-tree (Matt. xi. 21; Matt. xxxi. 20); as introducing the eschatological discourse (Mark xiii. 3 sqq.); and as prominent during the Last Supper (Luke xxii. 8 sqq.; John xiii. 4 sqq.; Mark xiv. 27 sqq.; Matt. xxvi. 31 sqq.). He
was present in Gethsemane, and tried to offer some resistance to the arrest of Jesus (Mark xiv. 47; Matt. xxvi. 51; Luke xxii. 50; John xviii. 10). After the arrest he followed the Lord to the scene of the trial, but denied him and fled. The message of the young man at the tomb (Mark xvi. 4) was especially addressed to Peter and it is clear that the genuine conclusion of Mark must have contained an account of an appearance of the risen Lord to him.

Out of this mass of incidents the following are central and call for closer critical consideration.

1. The Call of St. Peter.—(Mark i. 16–20; Matt. iv. 18–22; Luke v. 1–11; John i. 40–42). The account in Matthew is practically identical with that in Mark and is no doubt taken from the Marcan source, but Luke and John have different traditions. The main points are as follows: according to Mark, at the beginning of the Galilean ministry Jesus saw Peter and Andrew. He called them, and they joined him. After this he went with them to Capernaum, preached in the synagogue, and healed Peter’s wife’s mother. Luke, who certainly used Mark, has partly rearranged this narrative and partly rejected it in favour of a different version. According to him the visit to Capernaum and the healing of the wife’s mother preceded the call of Peter, and this was associated with a tradition of a miraculous draught of fishes. The advantage of the Lucan reconstruction, so far as the first part is concerned, is that it supplies a reason for Peter’s ready obedience, which is somewhat difficult to understand if he had never seen Jesus before. But it seems probable that this is the motive which led to the redactional change in Luke, and that the Marcan account, which is traditionally connected with Peter, ought to be followed. With regard to the narrative of the miraculous draught of fishes, the matter is more complicated. Luke obviously preferred this narrative to the Marcan account, but the fact that the same story comes in John xxi. suggests that there was an early tradition of some such incident of which the actual occasion and circumstances were undetermined. Luke preferred to connect it with the call of Peter, the writer of John xxi. with his restitution: probably both are of the nature of redactional guesses, and the Marcan account must be regarded as preferable to either. The Johannine account of the call of Peter is quite different. According to this it took place immediately after the baptism of Jesus, in Judaea not in Galilee. It is connected with the giving of the name Peter, which in Mark was not given until much later.

2. The Confession of Peter at Caesarea Philippi.—(Mark viii. 7–33; Matt. xvi. 13–23; Luke ix. 5–22). According to Mark, Peter, in the presence of the disciples, recognized that He was the Messiah, but protested against the prophecy of suffering which Jesus then added. This narrative is followed, with the exception of the last part, by Luke, who as usual is inclined to omit anything which could be regarded as derogatory to the Apostles. Matthew also uses the Marcan narrative, but adds to it a new section from some other source which suggests that the name of Peter was conferred on this occasion—not, as Mark says, at the first mission of the Twelve—and confers on him the keys of the kingdom of heaven and the right of binding and loosing. This must be probably interpreted as a reference to the prophecy concerning Elia in Isa. xxii. 22, and to technical use of the words “binding” and “loosing” by the scribes in authoritative decisions, as to the obligations of the law. It thus confers on Peter a position of quite unique authority. It must, however, be noted that the power of binding and loosing is given in Matt. xviii. 18 to the whole body of disciples. This seems to be an alternative version, also found only in Matthew. The question of the historical character of the Matthaean addition to the Marcan narrative is exceedingly difficult; but it is hard to think that if it were really authentic it would have been omitted from all the other gospels, and it perhaps belongs to the little group of passages in Matthew which seem to represent early efforts towards church legislation, rather than a strictly historical narrative. Besides it is noticeable that in one other point Matthew has slightly remodelled the Marcan narrative. According to the latter Jesus asked, “Whom say men that I am?” and Peter replied “the Messiah,” without qualification. But in Matthew the question is changed into “Whom say men that the Son of Man is?” and, whatever may be the original meaning of the phrase “the son of man,” it cannot be doubted that in the gospels it means Messiah. Thus the simple answer of Peter in Mark would be meaningless, and it is replaced by “The Messiah, the son of the living God,” which is no longer a recognition of the Messiahship of Jesus (this is treated in Matthew as an already recognized fact, cf. x. 23, xii. 40, etc.), but is a definition and an exaltation of the nature of the Messiah.

3. The Conduct of Peter after the Betrayal.—The consideration of this point brings one into touch with the two rival traditions as to the conduct of the disciples after the betrayal and crucifixion of the Lord—the Galilean and the Jerusalem narratives. There is one incident which must in any case be accepted as it is found in both narratives. This is the denial of Peter. It appears that Peter did not stay with the disciples and neither returned home immediately to Galilee (according to the Galilean tradition) nor sought hiding in Jerusalem (according to the Jerusalem tradition), but followed the Lord at a distance and was a witness of at least part of the trial before the Sanhedrin. He was detected and accused of being a disciple, which he denied, and so fulfilled the prophecy of Jesus that he would deny Him before the cock crowed.

But putting this incident aside, the Galilean and Jerusalem traditions do not admit of reconciliation with one another. The former is represented by Mark. According to it the disciples all fled after the betrayal (though Peter waited until after the denial), and afterwards saw the risen Lord in Galilee. The details of this narrative are unfortunately lost, as the genuine conclusion of Mark is not extant. But Mark xiv. 28 and xvi. 7 clearly imply a narrative which described how the disciples returned to Galilee, there saw the risen Lord, and perhaps even how they then returned to Jerusalem in the strength of their newly recovered faith, and so brought into existence the church of Jerusalem as we find it in the Acts. It is also clear from Mark xvi. 7 that Peter was in some special way connected with this appearance of the risen Lord, and this tradition is confirmed by 1 Cor. xv. 5 and perhaps by Luke xxiv. 34.

The Jerusalem narrative is represented especially by Luke and John (excluding John xxi. as an appendix). According to this the disciples, though they fled at the betrayal, did not return to their homes, but remained in Jerusalem, saw the risen Lord in that city, and stayed there until after the day of Pentecost. Attempts to reconcile these two narratives seem to be found in Matthew and in John xxi.

Obviously the choice which has to be made between these traditions cannot be adequately discussed here: it must suffice to say that intrinsic and traditional probability seem to favour the Galilean narrative. If so, one must say that after the denial Peter returned to Galilee—probably to resume his trade of fishing—and he there saw the risen Lord. This appearance is referred to in 1 Cor. xv. 5, and was certainly described in the lost conclusion of Mark. An account of it is preserved in John xxi., but it is here connected—probably wrongly—with a miraculous draught of fishes, just as the account of his call is in Luke.

Immediately after the resurrection there is a missing link in the history of Peter. We know that he saw the risen Lord, and, according to the most probable view, that this was in Galilee; but the circumstances are unknown, and we have no account of his return to Jerusalem, as at the beginning of the Acts the disciples are all in Jerusalem, and the writer, in contradiction to the Marcan or Galilean narrative, assumes that they had never left it. The first part of the Acts is largely concerned with
the work of Peter. He appears as the recognized leader of the Apostles in their choice of a new member of the Twelve to take the place of Judas Iscariot (Acts i. 15 sqq.); on the day of Pentecost he seems to have played a prominent part in explaining the meaning of the scene to the people (Acts ii. 14 sqq.); and soon afterwards was arrested by the Jews on the charge of being a ring-leader in the disorders caused by the healing of the lame man at the “Beautiful” gate of the temple, but was released. After this he appears as the leader of the apostles in the story of Ananias and Sapphira, who perished at his rebuke for their duplicity (Acts v. 1-11). The last episode of this period is another arrest by the priests, which ended in his being scourged and released (Acts v. 17 sqq.).

After this Peter’s attention was directed to the growth of Christianity in Samaria, and he and John made a journey of inspection through that district, laying hands on those who had been baptized in order that they might receive the Holy Spirit. Here Simon Magus (q.v.) was encountered. He was a magician who had been converted by Philip and baptized; he desired to obtain the power of conferring the Spirit, and offered Peter money for this purpose, but was indignantly repulsed. After this Peter and John returned to Jerusalem.

During the following stay in Jerusalem, the duration of which is not defined, Peter was visited by Paul (Acts ix. 26-29; Gal. i. 18), and a comparison of the chronological date afforded by Gal. i. and ii. points to a year not earlier than 33 (Harnack) or later than 38 (C. H. Turner) for this meeting. According to Galatians, Paul saw none of the apostles on this occasion except Peter and James: it is therefore probable that none of the others were then in Jerusalem.

After this Peter made another journey, visiting especially Lydda, Joppa and Caesarea. His stay at Lydda was marked by the healing of Aeneas (Acts ix. 32-4) and at Joppa by the resurrection of Tabitha or Dorcas. While at Joppa he stayed with Simon the tanner, and thence was summoned to Caesarea to Cornelius the centurion. He hesitated whether to go, but was persuaded by a vision and the injunction to call nothing unclean which God had cleansed. Cornelius was accordingly baptized. This is an important incident, as being the first admission of a Gentile into the church: but he was already “God-fearing,” φοβούμενος τὸν θεόν (Acts x. 1), which probably denotes some sort ofconnexion with the Jewish synagogue, though it is difficult to say exactly what it was. After this incident Peter returned to Jerusalem. The members of the Church were somewhat shocked at the reception of a Gentile: their view apparently was that the only road to Christianity was through Judaism. They were, however, persuaded by Peter’s speech (Acts xi. 4-18); but it is uncertain how far their concession went, and in the light of subsequent events it is probable that they still regarded circumcision as a necessary rite for all Christians.

After the return of Peter to Jerusalem the most important events were the famine at Jerusalem, and the persecution of the Church by Herod. During the latter Peter was put in prison (Acts xi. 27 sqq.), but was released by an angel; he first went to the house of Mary, the mother of John Mark, and afterwards went to “another place.” This expression has been interpreted to mean another town, and even to be an implied reference to Rome. This last suggestion, improbable though it be, is historically important. The persecution of Herod seems to have been in his last year, which was probably A.D. 43-44. There was a marked tendency to make the duration of Peter’s episcopate at Rome twenty-five years: and a combination of this tendency with the explanation that the εἰρήνη τῶν was Rome probably is the origin of the traditional dating of the martyrdom of Peter A.D. 67-68. There is, however, no justification for this view, and εἰρήνη τῶν need not mean more than another house in Jerusalem.

The famine referred to in Acts xi. 27 sqq. probably began before the death of Herod, but it continued after his death, and the relief sent by the church at Antioch to Jerusalem through Paul and Barnabas probably arrived about the year 45. It is not stated in the Acts that Peter was present, and it is therefore usually assumed that he was absent, but Sir W. M. Ramsay has argued in his St Paul the Traveller that the visit of Paul to Jerusalem with the famine relief is the meeting between Paul and Peter referred to in Gal. ii. as the occasion of an agreement between them as to the preaching of the gospel to Jews and Gentiles. This view is not generally accepted, but it has the great advantage of avoiding the difficulty that otherwise Paul in Gal. ii. 1 sqq. must describe as his second visit to Jerusalem what was really his third. According to Ramsay, then, Peter was present during the famine, and made a private agreement with Paul that the latter should preach to the Gentiles, and so far Gentile Christianity was recognized, but the conditions of the intercourse between Gentile and Jewish Christians were not defined, and the question of circumcision was perhaps not finally settled. According to the more popular view the description in Gal. ii. applies to Acts xv. the so-called council of Jerusalem. This council met after the first missionary journey (c. A.D. 45) of Paul to discuss the question of the Gentiles. Peter, who was present, adopted the view that Gentile Christians were free from the obligation of the law, and this view was put into the form of the so-called Apostolic decrees by James (Acts xv. 23 sqq.).

The next information which we have about Peter is given in Gal. ii. 11 sqq. According to this he went to Antioch and at first accepted the Gentile Christians, but afterwards drew back and was rebuked by Paul. On the ordinary interpretation this must have taken place after the council, and it is exceedingly difficult to reconcile it with the attitude of Peter described in Acts xv., so that Mr C. H. Turner thinks that in this respect the account in Gal. ii. is not chronological, and places the visit of Peter to Antioch before the council. If, however, we take the theory of Sir W. M. Ramsay the matter is simpler. We thus get the compact between Paul and Peter during the famine, then a visit of Peter to Antioch, during which Peter first adopted the custom of circumcision and afterwards drew back from the position which he had agreed to privately.

This vacillation may then have been one of the causes which led up to the council, which may have been held before, not, as is usually thought, after the sending of the Epistle to the Galatians. For this we have no knowledge of details for which the same certainty can be claimed. There are, however, various traditions of importance. The following points are noteworthy. 1 Cor. i. 12 suggests the possibility that Peter went to Corinth, as there was a party there which used his name. It is, however, possible that this party had merely adopted the principles which, as they had been told, perhaps falsely, were supported by the leader of the Twelve. Dionysius of Corinth (c. 170) states that Peter was in Corinth. This may represent local tradition or may be an inference from 1 Cor. i. 12. 1 Peter suggests a ministry in the provinces of Asia Minor. There is, of course, nothing improbable in this, and even if 1 Peter be not authentic, it is evidence for such a tradition, but it is also possible that Peter wrote to converts whom he had not personally made. This tradition is found in Origen (Eus. H.E. iii. 1), Epiphanius (Haer. xxvii., vi.), Jerome (De Vir. ill. 1) and other later writers; but it is possible that it is merely an inference from the epistle. Early tradition connects Peter with Antioch, of which he is said to have been the first bishop. The first writer to mention it is Origen (Hom. vi. in Lucam), but it is also found in the Clementine Homilies and Recognitions (Hom. 20, 23; Recog. 10, 68) and probably goes back to the lists of bishops which were drawn up in the 2nd century. Other important references to this tradition are found in Eus. H.E. iii. 26, 2; Apost. Const. vii. 46; Jerome, De Vir. ill. 1; Chronicon paschale; and Liber pontificum. The character of the work of Antioch may well be historical. Otherwise it is a rather wild elaboration of Gal. ii. 11. The most important and widespread tradition is that Peter came to Rome; and though this tradition has often been bitterly attacked, it seems to be probable that it is at least in outline quite historical. The evidence for it is earlier and better than that for any other tradition, though it is not quite convincing.

The earliest witness to a residence of Peter in Rome is probably
Peter, for (see Peter, Epistles of) it is probable that the reference to Babylon ought to be interpreted as meaning Rome. If so, and if the epistle be genuine, this is conclusive evidence that Peter was in Rome. Even if the epistle be not genuine it is evidence of the same tradition. Nor is corroboration lacking: Clement (c. A.D. 97) refers to Peter and Paul as martyrs (1 Clem. 5–6) and says that "To these men...there was gathered a great company of the elect who...became an example to us.

This points in two ways to a martyrdom of Peter in Rome, (1) because Peter and Paul are co-ordinated, and it is generally admitted that the latter suffered in Rome, (2) because they seem to be joined to the great company of martyrs who are to be an example to the Church in Rome. Similarly Ignatius (c. A.D. 115) says to the Romans (Rom. iv.), "I do not command you as Peter and Paul." The suggestion obviously is that the Romans had been instructed by these Apostles. By the end of the 2nd century the tradition is generally known: Irenaeus (3, 1, 1), Clement of Alexandria (on 1 Pet.) Origen (Hom. vi. in Lucam), Tertullian (Scorpi. 15, and several passages) are explicit on the point, and from this time onwards the tradition is met with everywhere. There is also a tradition, found in Irenaeus (3, 1, 1) and in many later writers, and supported by 1 Pet. v. 13, and by the statements of Papias (Eus. H. E. 3, 39, 15) that Mark acted as Peter's assistant in Rome and that his gospel is based on recollections of Peter's teaching.

This evidence is probably sufficient to establish the fact that Peter, like Paul, had a wide missionary career ending in a violent death at Rome, though the details are not recoverable. The chronological question is more difficult both as regards the beginning and the end of this period of activity.

The Acts, in describing the visits of Peter to Samaria, Joppa, Lydda and Caesarea, justify the view that his missionary activity began quite early. Gal. ii. 11 and 1 Cor. ix. 5 show that Acts minimizes rather than exaggerates this activity; the Antiochen tradition probably represents a period of missionary activity with a centre at Antioch; similarly the tradition of work in Asia is possibly correct as almost certainly is that of the visit to Rome. But we have absolutely no evidence justifying a chronological arrangement of these periods. Even the silence of Paul in the epistles of the captivity proves nothing except that Peter was not then present; the same is true of 2 Tim. even if its authenticity be undoubted.

The evidence as to the date of his death is a little fuller, but not quite satisfactory. The earliest direct witness is Tertullian, who definitely states that Peter suffered under Nero by crucifixion. Origen also relates the latter detail and adds that at his own request Peter was crucified head downwards. Probably John xxii. 18 seq. is still earlier reference to his crucifixion. Fuller evidence is not found until Eusebius, who dates the arrival of Peter at Rome in 43 and his martyrdom twelvemonths later. But the whole question of the Eusebian chronology is very confused and difficult, and the text of the Chronicon is not certain. The main objection to this date is based partly on general probability, partly on the language of Clement of Rome. It is more probable on general grounds that the martyrdom of Peter took place during the persecution of Christians in 64, and it is urged that Clement's language refers to this period. It is quite possible that an error of a few years has crept into the Eusebian chronology, which is probably largely based on early episcopal lists, and therefore many scholars are inclined to think that 64 is a more probable date than 67. As a rule the discussion has mainly been between these two dates, but Sir W. M. Ramsay, in his Church in the Roman Empire, has adopted a different line of argument. He thinks that 1 Peter was written c. A.D. 80, but that it may nevertheless be Petrine; therefore he lays stress on the fact that whereas the tradition that Peter was in Rome during life and probably until he was martyred under Nero is not found until much later. Thus he thinks it possible that Peter survived until c. 80, and was martyred under the Flavian emperors. The weak point of this theory is that Clement and Ignatius bring Peter and Paul together in a way which seems to suggest that they perished, if not together, at least at about the same time. If this view be rejected and it is necessary to fall back on the evidence between 64 and 67, the problem is perhaps insoluble, but 64 has somewhat more intrinsic probability, and 67 can be explained as due to an artificial system of chronology which postulated for Peter an episcopate of Rome of twenty-five years—a number which comes so often in the early episcopal lists that it seems to mean little more than "a long time," just as "forty years" does in the Old Testament. On the whole 64 is the most probable date, but it is very far from certain: the evidence is insufficient to justify any assurance.

For further information and discussion see especially Harnack's Chronologie, and Bishop Chae's article in Hastings's Dictionary of the Bible. The latter is in many ways the most complete statement of the present state of the evidence.

Caius, who lived in the beginning of the 3rd century (see Eus. H. E. 2, 25), stated that the τάφωρ (i.e. probably the burial place, not that of execution) of Peter and Paul were on the Vatican. This is also found in the Acta Petri, 84 (in the Lib. Pont., ed. Duchesne, p. 52 seq., 118 sqq.). From this place it appears that the relics (whether genuine or not) were moved to the catacombs in A.D. 258 (cf. the Depositis martyrum, and see Lightfoot's Clement, i. 249); hence arose the tradition of an original burial in the catacombs, found in the Hieronymian Martyrology.

**Peter I.**

The **Chronology of Peter's Wider Missionary Work**.

Peter I., called "the Great" (1672–1725), emperor of Russia, son of the tsar Alexius Mikhailovich and Natalia Narušinina, was born at Moscow on the 30th of May 1672. His earliest teacher (omitting the legendary Scotchman Menzies) was the dyak, or clerk of the Novgorod church, subsequently the court fool, who taught his pupil to spell out the liturgical and devotional books on which the children of the tsar were generally brought up. After Zotov's departure on a diplomatic mission, in 1690, the lad had no regular tutor. From his third to his tenth year Peter shared the miseries and perils of his family. His very election (1682) was the signal for a rebellion. He saw one of his uncles dragged from the palace and butchered by a savage mob. He saw his mother's beloved mentor, and his own best friend, Aratmon Mattveev, torn, bruised and bleeding, from his retaining grasp and hacked to pieces. The haunting memories of these horrors played havoc with the nerves of a supersensitive child. The convulsions from which he suffered so much in later years must be partly attributed to this violent shock. During the regency of his half-sister Sophia (1682–1698) he occupied the subordinate position of junior tsar, and after the revolution of 1689 Peter was still left pretty much to himself. So long as he could indulge freely in his favourite pastimes—ship-building, ship-sailing, drifting and sham fights—he was quite content that others should rule in his name. He now found a new friend in the Swiss adventurer, François Lefort, a shrewd and jovial rascal, who not only initiated him into all the mysteries of profligacy (at the large house built at Peter's expense in the German settlement), but taught him his true business as a ruler. His mother's attempt to wean her prodigal son from his dangerous and mostly disreputable pastimes, by forcing him to marry the beautiful but stupid Eudokia Lopukhina (Jan. 27, 1689), was a disastrous failure. The young couple were totally unsuited to each other. Peter practically deserted his unfortunate consort a little more than a year after their union.

The death of his mother (Jan. 25, 1694) left the young tsar absolutely free to follow his natural inclinations. Tiring of the great lake at Pereyaslavl, he had already seen the sea for the first time at Archangel in July 1688, and on the 1st of May 1694 returned thither to launch a ship built by himself the year before. Shortly afterwards he nearly perished during a storm in an adventurous voyage to the Solovetsky Islands in
the White Sea. His natural bent was now patent. From the first the lad had taken an extraordinary interest in the technical and mechanical arts, and their application to military and naval science. He was taught the use of the astrolabe (which Prince Yakov Doigoruik, with intent to please, had brought him from Paris) by a Dutchman, Franz Timmerman, who also instructed him in the rudiments of geometry and fortifications. He had begun to build his own boats at a very early age, and the ultimate result of these pastimes was the creation of the Russian navy. He had already surrounded himself with that characteristically Petrine institution "the jolly company," or "the company," as it was generally called, consisting of all his numerous personal friends and casual acquaintances. The company was gradually increased to a military and political; and the political was historical, and shared not only the orgies but also the labours of the tsar. Merit was the sole qualification for promotion, and Peter himself set the example to the other learners by gradually rising from the ranks. In 1663 he had only advanced to the post of "skirper" in his own navy and of "bombarider" in his own army. It was, however, the disreputable Lefort who, for the sake of his own interests, diverted the young tsar from mere pleasure to serious enterprises, by persuading him first to undertake the Azov expedition, and then to go abroad to complete his education.

By this time the White Sea had become too narrow for Peter, and he was looking about for more hospitable waters. The Baltic was closed door to Muscovy, and the White Sea was occupied by Sweden. The Caspian remained; and it had for long been a common saying with foreign merchants that the best way of tapping the riches of the Orient was to secure possession of this vast inland lake. But so long as the Turks and Tatars made the surrounding steppes uninhabitable the Caspian was a possession of but doubtful value. The first step making for security was to build a fleet strong enough to provide against the anarchical condition of those parts; but this implied a direct attack not only upon the Crimean khan, who was mainly responsible for the conduct of the Volgian hordes, but upon the khan's suzerain, the Turkish sultan. Nevertheless Peter did not hasten. War against Turkey was resolved upon, and Azov, the chief Turkish fortress in those regions, which could be approached by water from Moscow, became the Russian objective. From the 8th of July to the 22nd of September 1665 the Muscovites attempted in vain to capture Azov. The 22nd of November Peter re-entered Moscow. His first military expedition had ended in unmitigated disaster, yet from this disaster is to be dated the reign of Peter the Great.

Immediately after his return he sent to Austria and Prussia for as many sappers, miners, engineers and carpenters as money could procure. He meant to build a fleet strong enough to prevent the Turkish fleet from relieving Azov. The guards and all the workmen procurable were driven, forthwith, in bands, to all the places among the forests of the Don to fell timber at work day and night, turning out scores of vessels of all kinds. Peter himself lived among his workmen, himself the most strenuous of them all, in a small two-roomed wooden hut at Voronez. By the middle of April two warships, twenty-three galleys, four fireships and numerous smaller craft were safely launched. On the 3rd of May "the sea caravan" sailed from Voronez, "Captain Peter Aleksyevich" commanding the galleys-flotilla from the galley "Principium," built by his own hand. The new Russian fleet did all that was required of it by preventing the Turks from relieving Azov by water; and on the 18th of July the fortress surrendered. Peter now felt able to advance along the path of progress with a quicker and a firmer step. It was resolved to consolidate the victory by establishing a new naval station at the head of the Sea of Azov, to which the name of Taganrog was given. But it was necessary to guarantee the future as well as provide for the present. Turkey was too formidable to be fought single-handed, and it was therefore determined to send a grand embassy to the principal western powers to solicit their co-operation against the Porte. On the 10th of March 1697 this embassy, under the leadership of Lefort, set out on its travels. Peter attached himself to it as a volunteer sallorman, "Peter Mikhailov," so as to have greater facility for learning ship-building and other technical sciences. As a political mission it failed utterly, the great powers being at that period far more interested in western than in eastern affairs. But personally Peter learnt nearly all that he wanted to know—gunnery at Königsberg, shipbuilding at Saardam and Deptford, anatomy at Leiden, engraving at Amsterdam—and was proceeding to Venice to complete his knowledge of navigation when the revolt of the stryeltsy, or musketeers (June 1668), recalled him to Moscow. This revolt has been greatly exaggerated. It was suppressed in an hour's time by the tsar's troops, of whom only one man was killed; and the terrible vengeance (September-October 1668) which Peter on his return to Russia wreaked upon the captive musketeers was due not to any actual fear of these antiquated warriors, but to his consciousness that behind them stood the reactionary majority of the nation who secretly sympathized with, though they durst not assist, the rebels.

Peter's foreign tour had more than ever convinced him of the inherent superiority of the foreigner. Imitation had necessarily to begin with externals, and Peter at once fell foul of the long beards and Oriental costumes which symbolized the arch-conservatism of old Russia. On the 26th of April 1668 the chief men of the tsardom were assembled round his wooden hut at Porebrenshkovskoye, and Peter with his own hand was seen to clip off the beards and moustaches of his chief boyars. The ukas of the 1st of September 1668 allowed as a compromise that beards should be worn, but a graduated tax was imposed upon their wearers. The wearing of the ancient costumes was forbidden by the ukas of the 4th of January 1700; thenceforward Saxon or Magyar jackets and French or German hose were prescribed. That the people themselves did not regard the reform as a trifle is plain from the numerous rebellions against it. By the ukas of the 20th of December 1699 it was next commanded that henceforth the new year should not be reckoned, as heretofore, from the 1st of September, supposed to be the date of the creation, but from the first day of January, anno domini.

The year 1700 is memorable in Russian history as the starting-point of Peter's long and desperate struggle for the hegemony of the north. He had concluded peace with the Porte (June 13, 1700) on very advantageous terms, in order to devote himself wholly to a war with Sweden to the end that Russia might gain her proper place on the Baltic. The possession of an ice-free seaboard was essential to her natural development; the creation of a fleet would follow inevitably upon the acquisition of such a seaboard; and she could not hope to obtain her due share of the trade and commerce of the world till she possessed both. All the conjunctures seemed favourable to Peter. The Swedish government was in the hands of an untired lad of sixteen; and the fine fleets of Denmark, and the veteran soldiers of Saxony, were on the same side as the myriads of Muscovy. It seemed an easy task for such a coalition to wrest the coveted spoil from the young Charles XII.; yet Peter was the only one of the three conspirators who survived the Twenty-one Years' War in which they so confidently embarked during the summer of 1701. He was also the only one of them who got anything by it. Charles's "immersion in the Polish bog" (1702-1707), as Peter phrased it, enabled the tsar, not without considerable expense and trouble, to conquer Ingria and lay the foundations of St Petersburg. In these early days Peter would very willingly have made peace with his formidable rival if he had been allowed to retain these comparatively modest conquests. From 1709 to 1709 that war in which Peter had sacrificed so much in ameliorating Russia, and which he had declared to be solely defensive; Charles would not hear of peace till full restitution had been made and a war indemnity paid, while Peter was fully resolved to persist rather than surrender his "paradise," Petersburg. After Pultava (June 26, 1709), Peter, hitherto commendably cautious even to cowardice, but now puffed up with pride, rashly plunged into as foolhardily an enterprise as ever his rival engaged in. The campaign of the Pruth (March to July 1711) must have been fatal to the
tsar but for the incalculable behaviour of the omnipotent grand vizier, who let the Russian army go at the very instant when it lay helpless in the hollow of his hand. Even so, Peter, by the peace of the Pruth, had to sacrifice all that he had gained by the Azov expedition fifteen years previously. On receiving the tidings of the conclusion of the peace of Nystad (August 30, 1721), Peter declared, with perfect justice, that it was the most profitable peace Russia had ever concluded. The gain to Russia was, indeed, much more than territorial. In surrendering the pick of her Baltic provinces, Sweden had surrendered along with them the hegemony of the north, and all her pretensions to be considered a great power.

The Great Northern War was primarily a training school for a backward young nation, and in the second place a means of multiplying the material resources of a nation as poor as she was backward. During the whole course of it the process of internal domestic reformation had been slowly but unceasingly proceeding. Brand-new institutions on Western models were gradually growing up among the ambigious, antiquated, worn-out machinery of old Muscovy; and new men, like Menshikov, Goloykin, Apраксин, Osterman, Kurakin, Tolstoy, Shafirov, Prokopovich, Yaguzhinsky, Yavorsky, all capable, audacious, and brimful of new ideas, were being trained under the eye of the great regenerator to help him to carry on his herculean task. At first the external form of the administration remained much the same as before. The old dignities disappeared of their own accord with the deaths of their holders, for the new men, those nearest to Peter, did not require them. "The Administrative Senate" was not introduced till 1711, and only then because the interminable war, which required Peter's prolonged absence from Russia, made it impossible for him to attend to the details of the domestic administration. Still later came the "Spiritual Department," or "Holy Synod" (1721), which superseded the ancient patriarchate. It was established, we are told, "to make simple folks cannot distinguish the spiritual power from the sovereign power, and suppose that a supreme spiritual pastor is a second sovereign, the spiritual authority being regarded as higher and better than the temporal." From the first the regenerator in his ukases was careful to make everything quite plain. He was always explaining why he did this or that, why the new was better than the old, and so on; and we must recollect that these were the first lessons of the kind the nation had ever received. The whole system of Peter was deliberately directed against the chief evils from which old Muscovy had always suffered, such as dissipation of energy, dislike of co-operation, absence of responsibility, lack of initiative, the tyranny of the family, the insincerity of the individual. The low social morality of all classes, even when morality was most at its height, necessitated the regeneration of the nation against its will, and the process could therefore only be a violent one. Yet the most enlightened of Peter's contemporaries approved of and applauded his violence; some of them firmly believed that his most energetic measures were not violent enough. Thus Ivan Poroshkov, Peter's contemporary, the father of Russian political economy, writes as follows: "If any land be over-much encumbered with weeds, corn cannot be sown thereon unless the weeds first be burned with fire. In the same way, our ancient inveterate evils should also be burnt with fire." Peter himself carried this principle to its ultimate limits in dealing with his unfortunate son the Tsarevich Alexius (q.v.). From an ethical and religious point of view the deliberate removal of Alexius was an abominable, an inhuman crime: Peter justified it as necessary for the welfare of the new Russia which he had called into existence.

The official birthday of the Russian empire was the 22nd of October 1721, when, after a solemn thanksgiving service in the Troitsky, a special act for the peace of Nystad, the tsar proceeded to the senate and was there acclaimed: "Father of the Fatherland, Peter the Great, and Emperor of All Russia." Some Russians would have preferred to proclaim Peter as emperor of the East; but Peter himself adopted the more patriotic title.

Towards the end of the reign the question of the succession to the throne caused the emperor some anxiety. The rightful heir, in the natural order of primogeniture, was the little grand duke Peter, son of the Tsarevich Alexius, a child of six; but Peter decided to pass him over in favour of his own beloved consort Catherine. The usat, or ordinance of 1722, heralded this unheard-of innovation. Time-honoured custom had hitherto reckoned primogeniture in the male line as the title to the Russian crown; in the usat of 1722 Peter denounced primogeniture in general as a stupid, dangerous, and even unscriptural practice of dubious origin. The usat was but a preliminary step to a still more sensational novelty. Peter had resolved to crown his consort empress, and on the 15th of November 1723 he issued a second manifesto explaining at some length why he was taking such an unusual step. That he should have considered any explanation necessary demonstrates that he felt himself to be treading on dangerous ground. The whole nation listened aghast to the declaration. The coronation of a woman was in the eyes of the Russian people a scandalous innovation in any case, and the proposed coronation was doubly scandalous in view of the base and disreputable origin of Catherine herself (see CATHERINE I). But Peter had his way, and the ceremony took place at Moscow with extraordinary pomp and splendour on the 7th of May 1724.

During the last four years of his reign Peter's policy was predominantly Oriental. He had got all he wanted in Europe, but the anarchical state of Persia at the beginning of 1722 opened up fresh vistas of conquest. The war which lasted from May 1722 to September 1723 was altogether successful, resulting in the acquisition of the towns of Baku and Derbent and the Caspian provinces of Gilan, Mazandaran and Astarabad. The Persian campaigns wore out the feeble health of Peter, who had been illing for some time. A long and fatiguing tour of inspection over the latest of his great public works, the Ladoha Canal, during the autumn of 1724, brought back another attack of his paroxysms, and he reached Petersburg too ill to rally again, though he showed himself in public as late as the 16th of January 1725. He expired in the arms of his consort, after terrible suffering, on the 28th of January 1725.

Peter's claim to greatness rests mainly on the fact that from first to last he clearly recognized the requirements of the Russian nation and his own obligations as its ruler. It would have materially lightened his task had he placed intelligent foreigners at the head of every department of state, allowing them gradually to train up a native bureaucracy. But for the sake of the independence of the Russian nation he resisted the temptation of taking this inviting but perilous short-cut to greatness. He was determined that, at whatever cost, hardship and inconvenience, Russia should be ruled by Russians, not by foreigners; and before his death he had the satisfaction of seeing every important place in his empire in the hands of capable natives of his own training. But even in his most sweeping reforms he never lost sight of the idiosyncrasies of the people. He never destroyed anything which he was not able to replace by something better. He possessed, too, something of the heroic nature of the old Russian bogatyr, or demigod, as we see them in the skazki and the bullinii. His expansive nature loved width and space. No doubt this last of the bogatiurs possessed the violent passions as well as the wide views of his prototypes. All his qualities, indeed, were on a colossal scale. His rage was cyclonic: his hatred rarely stopped short of extermination. His banquets were orgies, his pastimes convulsions. He lived and he loved like one of the giants of old. There are deeds of his which make humanity shudder, and no man equally great has ever descended to such depths of cruelty and treachery. Yet it may generally be allowed that a strain of public work, of which we occasionally catch illuminating glimpses, extorts from time to time an all-forgiving admiration. Strange, too, as it may sound, Peter the Great was at heart profoundly religious. Few men have ever had a more intimate persuasion that they were but instruments for good in the hands of God.
Catherine accepted it as a matter of course, provided that her own relations with the handsome young guardian, Gregory Orlov, were undisturbed. Nor was Peter's behaviour to his consort in public of the outrageous character we have been led to suppose. Peter, in fact, was too good-natured and inconsequent to pursue, or even premeditate, any deliberate course of ill treatment. No personal wrongs, but the deliberate determination of a strong-minded, capable woman to snatch the reins of government from the hands of a semi-imbecile, was the cause of Peter's overthrow, and his stupendous blunders supplied Catherine with her opportunity. Peter's foreign policy was the absolute reversal of the policy of his predecessor. He had not been on the throne for two months when he made pacific overtures to the wellnigh vanquished king of Prussia, whom he habitually alluded to as "the king my master." Peter's enthusiastic worship of Frederick resulted in a peace (May 5) and then (June 19) in an offensive and defensive alliance between Russia and Prussia, whereby Peter restored to Prussia all the territory won from her by Russia during the last five years at such an enormous expense of men and money, and engaged to defend Frederick against all his enemies. This was followed up by a whole series of menacing rescripts addressed by Peter to the courts of the European powers. Austria, however, at last, and at least in spirit, and with the consent of the Tsarina, the wife of Peter, had made all the preparations for a peaceful solution of the question. Catherine was encouraged and supported by her husband. Finally she picked a quarrel with Denmark for not accepting as an ultimatum the terms to be submitted by Russia to a peace conference to meet at Berlin for the purpose of adjusting the differences between the two powers. On the 6th of July the Russian army received orders to invade Denmark by way of Mecklenburg. This advance was only arrested, when the opposing forces were almost within touch of each other, by the tidings that a revolution had taken place at St Petersburg, and that Peter III. was already a prisoner in the hands of his consort. The coup d'état of the 9th of July 1762 properly belongs to the history of Catherine II. (q.v.). Here only a few words must be said as to the mysterious death of Peter at the castle of Ropsha, to which he was removed immediately after his surrender. Here he remained from the evening of the 9th to the afternoon of the 18th of July. At first Catherine and her counsellors could not make up their minds what to do with the former emperor. Imprisonment in Schlüsselburg or Exile or repatriation to his homeland were all proposed, and none of them were rejected as dangerous. The Orlov had even stronger motives than Catherine for suppressing the ex-emperor, for Gregory Orlov aspired to win the hand as well as the heart of his imperial mistress, and so long as Catherine's lawful husband lived, even in a prison, such a union would be impossible. The available evidence points to the irresistible conclusion that on the afternoon of the 18th of July 1762, Peter III., with his consort's consent, was brutally murdered at Ropsha by Alexius Orlov, Theodore Baryatsinski, and several other persons still unknown.

See R. N. Bain, Peter III., Emperor of Russia (London, 1902); V. A. Bilbasov, History of Catherine II. (Russ.), vol. I. (Berlin, 1906).

Peter (Pedro), the name of several Spanish kings.

Peter I., king of Aragon (d. 1104), son of Sancho Ramirez, the third in order of the historic kings of Aragon, belonged to times anterior to the authentic written history of his kingdom; and little is known of him save that he recovered Huesca from the Mahomedans in 1066.

Peter II., king of Aragon (1174-1213), son of Alphonso II. and his wife Sancia, daughter of Alphonso VIII. of Castile, was born in 1174. He had a very marked and curious personal character. As sovereign of lands on both sides of the Pyrenees, he was affected by very different influences. In his character of Spanish prince he was a crusader, and he took a distinguished part in the great victory over the Almohades at the Navas de Tolosa in 1212. But his lands to the north of the Pyrenees brought him into close relations with the Albigenses. He was a favourite of the troubadours, and in his ways of life he indulged in the laxity of Provençal morals to the fullest extent. We are told in the chronicle written by Desclot soon after his time, etc.
that Peter was only trapped into cohabiting with his wife by the device which is familiar to readers of Measure for Measure. In the year after the battle of the Navas de Tolosa he took up arms against the crusaders of Simon of Montfort, moved not by sympathy with the Albigenses, but by the natural political hostility of the southern princes to the conquering intervention of the north under pretence of religious zeal. His son records the way in which he spent the night before the battle of Muret with a crucify of life which defies translation, and tells us that his father was too exhausted in the morning to stand at Mass, and had to be lifted into the saddle by his squires. Peter none the less showed the greatest personal valour, and his body, recognizable by his lofty stature and personal beauty, was found on the field after the rout (Sept. 12, 1213).

See Chronicle of James I. of Aragon, translated by J. Forster (London, 1846), and Life and Times of James the First the Conqueror, by F. Darwin Swift (Oxford, 1894).

Peter III., king of Aragon (1236-1286), son of James the Conqueror, and his wife Yolande, daughter of Andrew II. of Hungary, was born in 1236. Having married Constance, daughter of Manfred of Beneventum, he came forward as the representative of the claims of the Hohenstaufen in Naples and Sicily against Charles, duke of Anjou. Peter began the long strife of the Angevines and Aragonese parties in southern Italy. His success in conquering Sicily earned him the surname of "the Great." He repelled an invasion of Catalonia undertaken by the king of France in support of Charles of Anjou, and died on the 8th of November 1286.

For the personal character of Peter III., the best witness is the Chronicle of Ramon de Muntaner—reprinted in the original Catalan by R. Lanz, Literarischer Verein in Stuttgurt, vol. vii. (1844), and in French by Buchon, Coll. des chroniques nationales (Paris, 1824—1828). See also O. Cartellieri, Peter von Aragon und die Italienische Vesper (Heidelberg, 1904).

Peter IV., king of Aragon (d. 1387), son of Alphonso IV., and husband of Maria de Padilla, is known as "the Ceremonious" and also as "he of the dagger." He acquired the first title by the rigid etiquette he enforced, as one means of checking the excessive freedom of his nobles. The second name was given him because he wounded himself with his dagger in the act of cutting to pieces the so-called "charter of the Union," which authorised the rebellions of his nobles, and which he forced them to give up, after he had routed them at the battle of Epina in 1348. Of no man of the 14th century can it be more truly said that his life was a warfare on earth. He had first to subdue his nobles, and to annex the Balearic Islands to the crown of Aragon. When he had made himself master at home, he had to carry on a long and fierce contest with his namesake Peter the Cruel of Castile, which only terminated when Henry of Trastamara succeeded, largely with Aragonese help, in making himself king of Castile in 1369. Peter succeeded in making himself master of Sicily in 1377, but died the actual possession of the island to his son Martin. He was three times married: to Mary, daughter of Philip of Evreux, king of Navarre; to Eleanor, daughter of Alphonso IV. of Portugal; and to Eleanor, daughter of Peter II. of Sicily, his cousin. The marriage of his daughter by his third marriage, Eleanor, with John I. of Castile, carried the crown of Aragon to the Castilian line when his male representatives became extinct on the death of his son Martin in 1410.

See Zurita, Anales de Aragon (Saragossa, 1610).

Peter, "the Cruel," king of Castile (1333-1366), son of Alphonso XI. and Maria, daughter of Alphonso IV. of Portugal, was born in 1333. He earned for himself the reputation of monstrous cruelty which is indicated by the accepted title. In later ages, when the royal authority was thoroughly established, there was a reaction in Peter's favour, and an alternative name was found for him. It became a fashion to speak of him as El Justiciero, the executor of justice. Apologists were found to say that he had only killed men who themselves would not submit to the law or respect the rights of others. There is this amount of foundation for the plea, that the chronicler Lopez de Ayala, who fought against him, has confessed that the king's fall was regretted by the merchants and traders, who enjoyed security under his rule. Peter began to reign at the age of sixteen, and found himself subjected to the control of his mother and her favourites. He was immoral, and unfaithful to his wife, as his father had been. But Alphonso XI. did not imprison his wife, or cause her to be murdered. Peter certainly did the first, and there can be little doubt that he did the second. He had not even the excuse that he was passionately in love with his mistress, Maria de Padilla; for, at a time when he asserted that he was married to her, and when he was undoubtedly married to Blanche of Bourbon, he went through the form of marriage with a lady of the family of Castro, who bore him a son, and then deserted her. Maria de Padilla was only the one lady of his harem of whom he never became quite tired. At first he was controlled by his mother, but emancipated himself with the encouragement of the minister Albuquerque and became attached to Maria de Padilla. Maria turned him against Albuquerque. In 1354 the king was practically coerced by his mother and the nobles into marrying Blanche of Bourbon, but deserted her at once. A period of turmoil followed in which the king was for a time overpowered and in effect imprisoned. The dissensions of the party which was striving to coerce him enabled him to escape from Toro, where he was under observation, to Segovia. From 1356 to 1366 he was master, and was engaged in continual wars with Aragon, in which he showed neither ability nor daring. It was during this period that he perpetrated the series of murders which made him odious. He confined in nobody save the Jews, who were his tax-gatherers, or the Mahomedan guard he had about him. The profound hatred of the Christians for the Jews and Mudejares, or Mahomedans settled among them, dates from the years in which they were the agents of his unbridled tyranny. In 1366 he was assailed by his bastard brother Henry of Trastamara at the head of a host of fortune, and fled the kingdom without daring to give battle. Albuquerque was seized by the archbishop of Santiago, and the dean, Peralvarez. Peter now took refuge with the Black Prince, by whom he was restored in the following year. But he disgusted his ally by his faithlessness and ferocity. The health of the Black Prince broke down, and he left Spain. When thrown on his own resources, Peter was soon overthrown by his brother Henry, with the aid of Bertrand du Guesclin and a body of French free companions. He was murdered by Henry in du Guesclin's tent on the 23rd of March 1369. His daughters by Maria de Padilla, Constance and Isabella, were respectively married to John of Gaunt, and Edmund, duke of York, sons of Edward III., king of England.

The great original but hostile authority for the life of Peter the Cruel is the Chronicle of the Chancellor Pero Lopez de Ayala (Madrid 1779-1780). A brilliantly written Life is that by Prosper Massardes, Hist. de Don Père I., roi de Castille (Paris, 1848).

PETER DES ROCHES (d. 1238), bishop of Winchester under John and Henry III., and conspicuous among the foreign favourites to whom these sovereigns owed much of their unpopularity, was a Poitevin by extraction. He received the office of chamberlain towards the close of Richard's reign, and under Richard's successor became an influential counsellor. In 1205, doubtless through John's influence, he was elected to the see of Winchester. His election was disputed but, on appeal, confirmed by Pope Innocent III., who honoured Peter by consecrating him in person. None the less, the new bishop stood by his royal patron during the whole period of the interdict. In 1213 he was made justiciar in succession to Geoffrey Fitz Peter. This promotion was justified by the fidelity with which Peter supported the king through the barons' war. At the battle of Lincoln (1217) Peter led a division of the royal army and earned some distinction by his valour; but he played a secondary part in the government so long as William Marshal held the regency. After Marshal's death (1219) Peter led the baronial opposition to Hubert de Burgh, with varying success. At first the justiciar was successful. In 1221 Peter mediated going on crusade; 1223-1224 saw his party broken up by Hubert's energetic measures; in 1227 he was himself dismissed from his office and...
turned his back on England to join the crusade of the emperor Frederick II. He was absent from England until 1231; but in the meantime enhanced his reputation both as a soldier and diplomatist. After the fall of De Burgh he kept in the background, but offices and honours were heaped on his dependants, especially on his nephew, Peter des Rievaulx, and other Poitevins. This foreign party triumphed over the revolt which was headed by Richard Marshal in 1233. But the-primate, Edmund Rich, voiced the general feeling when he denounced Peter as a mischief maker, and demanded that he should be dismissed from court. The king compelled, and threatened the bishop with charges of malversation. Peter was however permitted to leave the country with a pardon (1235); he conciliated Gregory IX. by rendering efficient aid in a war with the citizens of Rome (1235); and in the next year returned without molestation to his see. He was invited to go to the king's envoy to the court of Frederick II., but on returning was said to be sick almost from the score of ill health. His public reconciliation with De Burgh (1236), effected through the mediation of the papal legate, provided a dramatic close to their long rivalry, but had no political significance, since both were now living in retirement. Peter died in 1238, and was buried at Winchester. He was undoubtedly a man of a winning personality, a good diplomat and financier, a statesman whose unpopularity was due in some measure to his freedom from the insularity of the Englishmen, against whom he matched himself. But his name is associated with a worthless clique of favourites, and with the first steps which were taken by Henry III. to establish a feeble and corrupt autocracy.

PETER LOMBARD (c. 1100-c. 1160), bishop of Paris, better known as Magister sententiarum, the son of obscure parents, was born about the beginning of the 12th century, at Novara (then reckoned as belonging to Lombardy). At an early period during his education at Bologna, he went to France, bearing recommendation to Bernard of Clairvaux, who first placed him under Lotot at Reims, and afterwards sent him to Paris with letters to Gilduin, the abbot of St Victor. He soon became known as a teacher, and obtained a theological chair in the cathedral school. His famous textbook, the Sententiae, was written between 1145 and 1150. On the 29th of June 1150 he became bishop of Paris. The accounts of his bishopric are satisfactory. There is a charge that he was guilty of simony, having received his office through the favour of Philip, brother of Louis VII., his former pupil. The date of his death is uncertain. According to one account he died on the 20th of July 1160, and as Maurice de Sully became bishop that year the statement seems probable. Yet there is evidence for a later date, and he may have been set off for some years.

His famous theological handbook, Sententiarum libri quatuor, is, as the title implies, primarily a collection of opinions of the fathers, "sententiae patrum." These are arranged, professedly on the basis of the aphorism of Augustine, Lombard's favourite author—"Omne verbum Christi est scriptum vel potius verbum Christi in verbis," of which the first treats of God, the second of the creature, the third of the incarnation, the work of redemption, and the virtues, and the fourth of the seven sacraments and eschatology. The Sententiae show the influence of Abelard both in method and arrangement, but lack entirely the daring of Sic et Non. Compared with that book they are tame. Gratian's Concordia discordantium canonum, as he called his Decretum, was another strong influence. Lombard's Sententiae influenced for the better the teaching of the canon lawyers. The influence of Hugh of St Victor is also marked. The relation to the "sentences" of a Gandulphus of Bologna (still unpublished) has not been established. The most important thing in the book was its crystallization of the doctrine concerning the sacramental system, by the constant repetition of the same doctrine of the seven sacraments, and the acceptance of a definition of sacrament, not merely as "a sign of a sacred thing," but as itself "capable of conveying the grace or the act; it is the sign." The sentences soon attained immense popularity, ultimately becoming a textbook of the theological school, and giving rise to endless commentaries, over 180 of these being written in England. In 1300 the theological professors of Paris agreed in the rejection of sixteen propositions taken from Lombard, but their decision was far from obtaining universal currency.

Besides the Sententiae, Lombard wrote numerous commentaries (e.g. on the Patres, Cambriades, Job, the Gospel, Haraziphel and the Pauline Epistles), sermons and letters, which still exist in MS. The Glossae sue commentarius in psalmos Davidis, were first published in Paris in 1533. Lombard's collected works have been published in J. P. Migne's Patrologia latina, Tomes 191 and 192. See also Denifle and Chatelin, Chartularium universitatis parisinensis, Tome i. (Paris, 1889); Proteus, Pierre Lombard, son époque, sa vie, ses écris, son influence (Paris, 1885); Dupont, Pierre Lombard, le dogme, la philosophie, les méthodes (Leipzig, 1897); A. Harnack, Dogmengeschichte, Bd. iii. (1890; Eng. trans. 1894-1899); and the article in Herzog-Hauck's Realencyclopadie, Bd. xi. (Leipzig, 1902).

PETER OF AIGUEBLANCHE (d. 1268), bishop of Hereford, belonged to a noble family of Savoy and came to England in 1236 with his master, William of Savoy, bishop of Valence, being in attendance on Eleanor of Provence, the bride of Henry III. A year or two later he is found residing permanently in England as a member of the king's court; before 1259 he was archdeacon of Salop, and in 1240 he was chosen bishop of Hereford. In 1255 Peter acted as Henry's principal agent in the matter of accepting the kingdom of Sicily from Pope Alexander IV. for his son Edmund, and his rapacious and dishonest methods of raising money for this foolish enterprise added not a little to the unpopularity which surrounded the king and his foreign favourites. When civil war broke out between Henry and his barons the bishop remained loyal to his master, and whilst residing, almost for the first time, at Hereford he was taken prisoner in May 1263. He was, however, released when the king and his enemies came to terms, and after a stay in France he retired to Savoy, where he died on the 27th of November 1268.

See F. Mugnier, Les Savoyards en Angleterre au XIIe siècle et Pierre d'Aiguesblanche (Chambéry, 1890).

PETER OF BLOIS [PETRUS BLESSENSIS] (c. 1135-c. 1205), French writer, the son of noble Breton parents, was born at Blois. He studied jurisprudence at Bologna and theology in Paris, and in 1167 he went to Sicily, where he became tutor to the young king William II., and Keeper of the royal seal (sigillarius). But he made many enemies and soon asked permission to leave the country; his request was granted and about 1170 he returned to France. After spending some time teaching in Paris and serving Rotrou de Perche, bishop of Rouen, as secretary, Peter entered the employ of Henry II. of England about 1173. He quickly became archdeacon of Bath and soon afterwards chancellor or secretary; to Richard, archbishop of Canterbury, and afterwards to Baldwin, being sent on two occasions to Italy to plead the cause of these prelates before the pope. After the death of Henry II. in 1189, he was for a time secretary to his widow, Eleanor, in Normandy; he obtained the posts of dean of Wolverhampton and archdeacon of London, but he appears to have been very discontented in his later years. He died some time after March 1204.

Peter's writings fall into four classes, letters, treatises, sermons and poems. His Epistolas, which were collected at the request of Henry II., are an important source for the history of the time; they are addressed to Henry II. and to various prelates and scholars, including Thomas Becket and John of Salisbury. His treatises include De Ierosolymitana peregrinatione accelerata, an exhortation to take part in the third crusade, and Dialogus inter regem Henricum Lii et abbatem Giovannilenses: his extant sermon number 65 and his poems are unimportant. Peter's works have been printed in several collections, including the Patrologia of J. P. Migne and the Historiae Francorum scriptores of A. Duchene. Of separate editions are Peter of Blois's Poems of Geoffrey of Goussiavin (Paris, 1667) and J. A. Giles (Oxford, 1846-1847).

PETER OF COURTENAY (d. 1219), emperor of Romania (or Constantiople), was a son of Peter of Courtenay (d. 1183), and a grandson of the French king, Louis VI. Having, by a first marriage, obtained the counties of Nevers and Auxerre, he took
PETER OF DUISBURG—PETER THE HERMIT

for his second wife, Yolande (d. 1219), a sister of Baldwin and Henry of Flanders, who were afterwards the first and second emperors of the Latin Empire of Constantinople. Peter accompanied his cousin, King Philip Augustus, on the crusade of 1190, fought against the Albigenenses, and was present at the battle of Bouvines in 1214. When his brother-in-law, the emperor Henry, died without sons in 1216, Peter was chosen as his successor, and with a small army set out from France to take possession of his throne. Consecrated emperor at Rome, in a church outside the walls, by Pope Honorius III. on the 9th of April 1217, he borrowed some ships from the Venetians, promising in return to conquer Durazzo for them; but he failed in this enterprise, and sought to make his way to Constantinople by land. On the journey he was seized by the despot of Epirus, Theodore Angelus, and, after an imprisonment of two years, died, probably by foul means. Peter thus never governed his empire, however, was ruled for a time by his wife, Yolande, who had succeeded in reaching Constantinople. Two of his sons, Robert and Baldwin, became in turn emperors of Constantinople.

PETER OF DUISBURG (d. c. 1236), German chronicler, was born at Duisburg, and became a priest-brother of the Teutonic Order. He wrote the Chronicon terrae Prussiae, dedicated to the grand-master, Werner of Orselin, which is one of the chief authorities for the history of the order in Prussia. There is a rhyming translation in German by Nicholas of Jeroschin, which, together with the original, is published in Bd. I. of the Scriptores rerum prussicarum (Leipzig, 1861).

See M. Töppen, Geschichte der preussischen Historiographie (Berlin, 1852); and W. Fuchs, Peter von Duisburg und das Chronicon owenise (Königsberg, 1884).

PETER OF MARICOURT (13th century), a French savant, to whom his disciple, Roger Bacon, pays the highest tribute in his opus tertium and other works. According to Bacon he was a recluse who devoted himself to the study of nature, was able to work metals, invented armour and assisted St Louis in one of his expeditions more than his whole army. According to Émile Charles (Roger Bacon sa vie, ses ouvrages, ses doctrines, 1861), Peter of Maricourt is the Pierre Pégrèrin (or Pélérin) de Maricourt (Méharicourt in Picardy), known also as Petrus Peregrinus of Picardy, one of whose letters, De magnete, is partly reproduced in Libri des sciences mathématiques en Italie (1838), ii. 70-71, 487-505.

PETER OF SAVOY (c. 1203-1268), earl of Richmond, younger son of Thomas I. (Tommasso), count of Savoy, was born at Susa. After spending some years as an ecclesiast he resigned his prelatures, and in 1234 married his cousin Agnes, daughter and heiress of Aymon II., lord of Faucigny. Accepting an invitation from the English king, Henry III., who had married his niece, Eleanor of Provence, Peter came to England in 1249, and was created earl of Richmond, receiving also large estates and being appointed to several important offices. During several visits to the continent of Europe Peter had largely increased his possessions in Vaud and the neighbourhood, and returning to England in 1252 he became associated with Simon de Montfort, retaining at the same time the king's friendship. Having been employed by Henry to negotiate with the pope and with Louis IX. of France, he supported Earl Simon in his efforts to impose restrictions upon the royal power; but, more moderate than many members of the baronial party, went over to Henry's side in 1256, and was consequently removed from the council. In 1263 he left England, and when his nephew, Boniface, count of Savoy, died in the same year he assumed the title of count of Savoy. This was also claimed by another nephew, Thomas; but Peter compelled the inhabitants of Turin to submit to him and secured possession of the county. He died on the 16th or 17th of May 1268, leaving an only child, Beatrice (d. 1310). Peter gave to the castle of Chillon its present form, and his name to the Savoy palace in London. He has been called le petit Charlemagne, and was greatly praised for his valour and his wisdom.

See L. Wurstemberger, Peter der Zweite, Graf von Savoyen (Zürich, 1858); F. Mugnier, Les Savoyards en Angleterre (Chambery, 1890); and C. Bémont, Simon de Montfort (Paris, 1884).

PETER THE HERMIT, a priest of Amiens, who may, as Anna Commena says, have attempted to go on a pilgrimage to Jerusalem before 1066, and have been prevented by the Turks from reaching his destination. It is uncertain whether he was present at Urban's great sermon at Clermont in 1095; but it is certain that he was one of the preachers of the crusade in France after that sermon, and his own experience may have helped to give fire to his eloquence. He soon leapt into fame as an emotional revivalist preacher: his very air became an object of popular adoration; and thousands of peasants eagerly took the cross at his bidding. The crusade of the pauperes, which forms the first act in the first crusade, was his work; and he himself led one of the five sections of the pauperes to Constantinople, starting from Cologne in April, and arriving at Constantinople at the end of July 1096. Here he joined the only other section which had succeeded in reaching Constantinople—that of Walter the Loess; and with the joint forces, which had made themselves a nuisance by pillaging, he crossed to the Asiatic shore in the beginning of August. In spite of his warnings, the pauperes began hostilities against the Turks; and Peter returned to Constantinople, either in despair at their recklessness, or in the hope of procuring supplies. In his absence the army was cut to pieces by the Turks; and he was left in Constantinople without any followers, during the winter of 1096-1097, to wait for the coming of the princes. He joined himself to their ranks in May 1097, with a little following which he seems to have collected, and marched with them through Asia Minor to Jerusalem. But he played a very subordinate part in the history of the first crusade. He appears, in the beginning of 1098, as attempting to escape from the privations of the siege of Antioch—showing himself, as Guilbert of Nongent says, a "fallen star." In the middle of the year he was sent by the princes to invite Kerbogha to settle his differences by a duel; and in 1099 he appears as treasurer of the arms at the siege of Arca (March), and as leader of the supplicatory processions in Jerusalem which preceded the battle of Ascalon (August). At the end of the year he went to Laodicea, and sailed thence for the West. From this time he disappears; but Albert of Aix records that he died in 1151, as prior of a church of the Holy Sepulchre which he had founded in France.

Legend has made Peter the Hermit the author and originator of the first crusade. It has told how, in an early visit to Jerusalem, before 1066, Christ appeared to him in the Church of the Sepulchre, and bade him preach the crusade. The legend is without any basis in fact, though it appears in the pages of William of Tyre. Its origin is, however, a matter of some interest. Von Sybel, in his Geschichte des ersten Kreuzzuges, suggests that in the camp of the pauperes (which existed side by side with that of the knights and grew increasingly large as the crusade told more and more heavily in its progress on the purses of the crusaders) some idolization of Peter the Hermit had already begun, during the first crusade, parallel to the similar glorification of Godfrey by the Lorrainers. In this idolization Peter naturally became the instigator of the crusade, just as Godfrey became the founder of the kingdom of Jerusalem and the legislator of the assizes. This version of Peter's career seems odd as the Chanson des chêifs, a poem which Raymond of Antioch caused to be composed in honour of the Hermit and his followers, soon after 1150. It also appears in the pages of Albert of Aix, who wrote somewhere about 1150; and from Albert it was borrowed by William of Tyre. The whole legend of Peter is an excellent instance of the legendary amplification of the first crusade, an amplification which, beginning during the crusade itself in the "idolations" of the different camps (idola castri, if one may pervert Bacon), soon developed into a regular saga. This saga found its most piquant beginning in the Hermit's vision at Jerusalem, and there it accordingly began—alike in Albert, followed by William of Tyre and in the Chanson des chêifs, followed by the later Chanson d'Antioche.

The original authorities for the story of Peter the Hermit are: for the authentic Peter, Anna Commena and the Gesa Francorum;
for the legendary Peter, Albert of Aix. The whole career of the Hermit has been thoroughly and excellently discussed by H. Gagenmeyer, Peter der Hermit, (Leipzig, 1879).

PETER THE WILD BOY (f. 1725-1785), a Hanoverian imbecile of unknown parentage, who, having been found living wild in the woods near Hanover in 1725, was brought to England by order of George I., whose interest had been aroused in the unfortunate youth. An extraordinary amount of curiosity and speculation concerning Peter was excited in London, and the craze was the subject of a biting satire by Swift, and of another entitled The Most Wonderful Wonder that ever appeared to the Wonder of the British Nation, which has been attributed to Swift and Arbuthnot; Defoe also wrote on the subject, and Lord Monboddo in his Origin and Progress of Language presents the idiot as an illustration of his theory of the evolution of the human species. He lived to an advanced age, was seen by Lord Monboddo in 1782, and died in 1785. See Henry Wilson, The Book of Wonderful Characters, (London, 1869).

PETER, EPISTLES OF, the two books of the New Testament traditionally ascribed to the apostle Peter.

1 Peter

This epistle is addressed to "the elect who are sojourners of the Dispersion [Diaspora] in Pontus, Galatia, Cappadocia, Asia and Bithynia." The "Diaspora" was the name generally given to the Jews who were "scattered abroad." This suggests that the letter was intended for Jewish Christians in the provinces mentioned. But i. 14, 18; ii. 9, 10; iv. 3 point rather to Gentile Christians, and it is better to take this view, and interpret the "Diaspora" metaphorically as referring to the isolated position of Christians among the heathen. The general impression made by the epistle is that the central idea was to strengthen the courage of the recipients, who were likely to undergo persecution, and to enjoin on them conduct which would remove all reasonable excuse for thinking that Christianity ought to be a crime.

Ch. i. 3-12 is an introduction of praise to God that he had caused the recipients of the epistle to be born again to the living hope in a glorious salvation. The rest of the epistle may be divided into three parts: (a) i. 13-ii. 10, only Peter right to the end, is addressed to the elders of the churches, and the whole is completed by an exhortation to meekness and suffering in the suffering of Christ and the blessings given by them both to the living and to the dead; (b) iv. 7-11, less cohesion. It begins with exhortations not to forget prayer and love, and then returned to the duties of the elders and the young men. The elders and the younger men are reminded of their duties to the community and to one another. The whole is brought to a close with an exhortation to all to fight manfully against the devil, and to trust in God.

Date and Authorship.—These two questions are so closely connected that they cannot be considered separately. The external evidence of tradition is that the epistle was written by St. Peter. This can be traced back to Irenaeus (iv. 9, 2) and Clement of Alexandria (Strom. iii. 18, 110), and it is thought by many writers that 2 Peter iii. 1, even if it be not itself Petrine, is good evidence that the writer regarded 1 Peter as apostolic. Evidence for its use, without mention of its name, may be found in Polycarp, but probably not in the other apostolic fathers (cf. The N.T. in the Apostolic Fathers, Oxford, 1905, p. 137). It is, however, possible that Papias made use of it. It is doubtful whether Justin Martyr used it, but probable that it was known to Theophilus of Antioch. It is not mentioned in the canon of Muratori. Thus external evidence, though insufficient in favour of the Petrine authorship, is not sufficient to settle the question. The internal evidence consists of (a) evidence bearing on the date in connexion with the persecution of Christians, and (b) evidence establishing the relation of the epistle to other documents in early Christian history, and (γ) evidence concerning St. Peter personally.

(a) It is clear from 1 Peter i. 6, ii. 12, iv. 12-19, v. 9, that the epistle was written during a time of persecution, and the question which is doubtful is to which persecution the description applies. The traditional opinion was that the persecution referred to was that under Nero. But it has been argued that the Neroine persecution according to Tacitus (Ann. xv. 44) was not a persecution of Christians as such, but was rather the result of false accusation. Moreover there is no proof that there was any persecution of Christians at this time outside Rome, and 1 Peter alludes to persecution in the provinces of Asia Minor. Therefore many critics have supposed that the epistle is not to be dated to the persecution of Pliny to Trajan, written c. 112, and asking for advice as to the procedure to be followed in trials of Christians. This is, the earliest evidence which implies organized persecution in the provinces in question. W. Ramsay, among others, regard this as fixing the date of the epistle in the beginning of the 2nd century, and excluding the Petrine authorship. Against this view it may be urged that the epistle describes the beginning of persecution. The writer still hopes that Christians will not be obliged to "for the name of the Lord" sufferings of crime. On the other hand Pliny's letter implies a time when Christianity was in itself a crime and was recognized as such. Thus it is urged, probably correctly, that the epistle belongs to the beginning of a period of which Pliny's letter marks the beginning, and we can only say that c. 112 is the terminus ad quem. The terminus a quo is much more difficult to find. We do not know with certainty when Christianity became a recognized offence, and scholars have considered various cases and have arrived at different conclusions. Sanday thinks that if under Nero it was criminal to be a Christian; Neumann thinks that this was first the case under Domitian; Sir W. M. Ramsay believes that this attitude was one of the results of the Jewish War of 70, and attributes it to Vespasian. If the Domitanian date be adopted the Petrine authorship is almost excluded, and it is difficult to reconcile the traditional date of St. Peter's martyrdom with Ramsay's theory.

(b) The relations of 1 Peter to other books in early Christian literature is shown in the following table:

From this table it is sufficiently plain that 1 Peter is closely connected with Romans, Ephesians, and Polycarp. The majority of scholars are agreed that in the case of Romans the dependence is on the Pauline epistles, and in the case of Polycarp it is possible that 1 Peter also used other Pauline epistles. There is agreement as to Romans and James, though in the former case the general opinion favours the dependence of 1 Peter, in the latter case its priority. In England, however, the priority of James has been supported by Mayor and Hort. In the light of the established use of Romans it is possible that 1 Peter also used other Pauline epistles and some scholars have seen special traces of the influence of 1 Cor. and Gal. (for a list of these cf. Holtzmann, Einleitung in das N.T., 3, p. 314). It has been argued that the use of the Pauline epistles is improbable for Peter, but this is a subjective argument which is not decisive.

(γ) According to tradition Peter was martyred in Rome, and it is probable that this was in the Neronine persecution. If this be so, then the chief problem is to explain the authenticity of 2 Peter. But Ramsay, however, thinks that Peter may have survived this persecution and suffered at the beginning of the persecutions which he thinks were initiated by the Flavian emperors (see Peter, St.: 5, 6).

The whole question of authorship and date is thus a complex of smaller problems, many of which do not seem to admit of any definite answer. If St. Paul's epistle to the Ephesians be genuine, it may be really known to the writer of 1 Peter, and if Peter were martyred in 64, the theory of Petrine authorship demands that it was written by Peter between 59 and 64. On the Petrine hypothesis this is the most probable view. The weak point is that it assumes a great spread of Christianity in the provinces of Asia Minor outside the activity of Paul, and that the official persecution of Christians as such began throughout the Roman Empire under Nero, for neither of which there
corroborative evidence. On the non-Petrine hypothesis a date is demanded some time before the letter of Pliny; this suits the internal evidence better than any possible on the Petrine hypothesis, but it fails to explain the really considerable and early evidence for the Petrine authorship, and necessitates some purely hypothetical suggestion, such as Harnack's view that the epistle was originally anonymous, and that the opening and closing sentences (i. 1 sqq., v. 12 sqq.) were added between A.D. 150 and 175, perhaps by the writer of 2 Peter.

The Provenance of the Epistle.—This is defined in 1 Peter v. 13 as Babylon. It has sometimes been argued that this is Babylon in Mesopotamia, in which there were, until the time of the emperor Caius, many Jews; but no good tradition connects St Peter with the evangelization of Mesopotamia, and this district was the home of a primitive church of Asia Minor. Another suggestion is that the Egyptian Babylon is meant (Old Cairo); but in the 1st century this was probably merely a fortress. Thus there is an overwhelming weight of opinion in favour of the view that Rome, the Babylon of Apocalyptic literature, is intended. This also agrees with the tradition in Tim. iv. 11, which (cf. 1 Pet. v. 13) suggests that St Mark was in Rome.

Reception in the Canon.—1 Peter seems to have been the earliest of the Catholic epistles to obtain recognition. By the year 200 it was accepted everywhere except in two places—the church of Edessa, which did not receive the Catholic epistles until the 5th century, and, if the canon of Muratori is to be trusted, the church of Rome. It should, however, be noted that Zacharias affords the text of the Muratorianum (rather violently) so as to include the epistle (see also Bible: New Testament Canon.)

The Theology of Peter.—The simplicity of the theology is marked, and affords an argument for an early date. Jesus is the Messiah of whom the prophets had spoken, and the "Spirit of Christ" is identified with the spirit which was in him. His suffering for sin had been foreseen, and, with the little in common with the Graeco-Cidian world to follow. After his death he preached to the "saints in prison." The source of Christian life is on the one hand belief in God who raised the Messiah from the dead, and on the other hand baptism which "saves, through the resurrection of Jesus Christ." The members of the community are "a royal priesthood, a holy nation" with the promises made to the Jews, but this inheritance is bound up with the strong eschatological doctrine that Christians are strangers in the world, the end of which is at hand.

The Church Organization of Peter.—This also is very simple and primitive, and closely based on the Jewish model. The leaders are called presbyters or elders, and their duty is to act as shepherds to the flock. Beyond this there is no sign of a developed organization; each is to act in accordance with the gift (χάρισμα) which he has received. There is no trace of a specially set apart ministry either for the service of the community or for teaching, as to which the limitation given is "if any man speak let him speak as the oracles of God," i.e. probably, in accordance with the Old Testament.

2 Peter

This epistle may be divided into five parts. (1) The writer who describes himself as "Simon (var. lect. Symeon) Peter, a servant and apostle of Jesus Christ," exhorts his readers to become perfect in knowledge and virtue, so as to enter the kingdom of Christ (i. 3-11). (2) He then explains his desire more fully to test the power of Jesus, and bases his testimony partly on his own experience in the Holy Mount (apparently a code for the Transfiguration), and partly on the "word of prophecy" (i. 12-21). (3) The mention of prophecy leads him to deal with the question of false prophets, who are accused of false doctrine and immoral practices. In this section is incorporated almost the whole of the epistle of Jude (ii. 1-22). (4) He then discusses a special feature of the false teaching, viz. doubts thrown on the Parousia, the certainty of which for the future he defends (iii. 1-7). Finally he warns his hearers that they must be found spotless at the Parousia, and emphasizes the agreement of his teaching with St Paul's (iii. 14-18).

The main object of the epistle is to be seen in the attacks made on the false teachers, and in the defence of the certainty of the Parousia of the Lord.

Authorship.—The traditional view is that it was written by St Peter from Rome after 1 Peter. This view is however untenable for the following reasons. (1) The epistle is not quoted by any writer of the 2nd century, and Origen, who is the first to mention it as Petrine, admits that its authorship was disputed. (2) The style and language differ greatly from that of 1 Peter: this argument may however fairly be met by the suggestion that it is improbable that he wrote Greek with ease, and that he may have used a variety of amanuenses. (3) The growth of immorality and false teaching to which it witnesses seems irreconcilable with a very primitive period of church life. (4) It has incorporated the greater part of Jude in a wholesale manner difficult to reconcile with apostolic authorship. (5) It seems to attribute a position of scriptural authority to the Christian hope which is improbable either in the mouth of Peter, or during the 1st century.

Any one of these arguments would be weighty by itself; in combination they form an irresistible cumulative argument against the Petrine authorship of 2 Peter.

Date.—If the Petrine authorship is abandoned, the terminus ad quem of the epistle is its use by Origen (or, just possibly, by Clement of Alexandria), and the terminus a quo is fixed by the following considerations: (1) the activity of an immoral Gnosticism; (2) the attainment by the Pauline epistles of great authority, and their perversion by heretics; (3) the use made of the epistle of Jude.

It is difficult to define the exact date to which these indications point, but there is a general agreement that it must be sought in the 2nd century, and probably in the first half of the most, 100 are the most probable.

Place of Origin.—There is hardly any evidence on this point: but the most probable place seems to be Egypt, as the letter has points of connexion with Philo, Clement of Alexandria, and the Apocalypse of Peter, and seems first to have been used in the church of Alexandria. It should however be noted that Deissmann argues on lexical grounds in favour of Asia Minor (Bibl. Stud. pp. 277-284).

Relation to other Early Christian Documents.—The documents with which 2 Peter has the greatest affinities are the epistle of Jude, and the Apocalypse of Peter, of which a fragment was found in Akhmim in 1802 by M. Bourian. In each case the affinity is very close, and is capable of more than one explanation. Roughly speaking 2 Peter reproduces Jude; it is possible to see the Apocalypse of Peter as the outcome of an attempted imitation of 2 Peter used Jude. The former hypothesis has a few supporters, notably T. Zahn and Spitta, but most writers are emphatic in thinking that 2 Peter has incorporated Jude, and this view is almost certainly correct (see Jude, Epistle Of).

The connexion with the Apocalypse of Peter is more complicated: the evidence of a comparison between the two documents (which is made in full in F. H. Chase's article in Hastings's Dictionary of the Bible) is to show that either one document is dependent on the other, or both were written by the same person, or both come from the same circle. Of these theories there is least to be said for the dependence of the Apocalypse on 2 Peter, and perhaps most for the dependence of 2 Peter on the Apocalypse.

Reception in the Canon.—2 Peter was the last of the Catholic epistles to be accepted as canonical. It was first regarded as such in Alexandria, perhaps originally in connexion with the Apocalypse of Peter rather than with 1 Peter. Thence it passed into the canon used by the church of Constantinople, in the 4th century made its way into the Roman canon, and in the 6th was accepted last of all by the Syria church (see also Bible: New Testament Canon).

The Theology of 2 Peter.—The theology of the epistle is specially marked by two characteristics: its high Christology and its eschatological character. Christ is referred to as "our God and Saviour," and the fatherhood of God is apparently only regarded as referring to the Divine Son. The work of Christ was the redemption of the elect, and this redemption awaits its consummation in the Parousia. This is the central point of the teaching of the epistle and is obviously directed against that of the false prophets. The writer looks forward to the destruction of the present world by fire,
when the wicked, whether angels or men, who have been reserved for judgment will be finally condemned, and a new era of happiness for the elect will begin.

Church Organization.—There is very little in 2 Peter which throws light on the date of its composition. From his silence it has been thought that the monarchical episcopacy did not yet exist in the church to which the writer belonged; and perhaps the prophets were still the chief guides, but the argument from silence cannot be pressed. In any case, the episcopacy as instituted by St. Peter in the Apocalypse and ultimately led to the obsolescence and suppression of this order, was far advanced and was one of the reasons which led to the writing of the epistle.

AUTHORITIES.—Besides the books and articles already mentioned the following may be noted: F. A. J. W. Brunton, "2 Peter," in Hastings’ Dict. Bible; F. W. Schmieder, "Simon Peter" in the Ency. Bibl.; Lightfoot, S. Clement of Rome, i, 201-315 and 11, 481-502; Harnack, Alltbr. Litt. and Chronologie 1 (the relevant portion was printed in the Introduction for Holtzmann, T. Zahn. Jülicher, Salmon, Weiss and Moffatt. The commentaries of Bigg, Mayor, F. Spitta, Kühl (in Meyer’s Commentary), von Soden (in Holtzmann’s Commentary), and Weiss.

PETERBOROUGH, a town and port of entry of Ontario, Canada, and capital of Peterborough county, situated 70 m. N.E. of Toronto, on the Otonabee river and the Grand Trunk and Canadian Pacific railways. Pop. (1901), 11,250. The five fells of Otonabee at this point, with a total descent of 50 ft., furnish power for a large and increasing number of manufacturing establishments, whilst its canalization as part of the Trent canal gives communication with Lake Ontario and Georgian Bay. Peterborough has an electric railway, and contains important manufactories of electrical machinery and supplies, iron and steel bridges, agricultural implements and cordage, saw, flour and woolen mills.

PETERBOROUGH, a city and municipal and parliamentary borough of Northamptonshire, England, 76 m. N. from London by the Great Northern railway; served also by the London & North Western. Great Eastern and Midland railways. (1801), 25,171; (1901), 30,872. It is built chiefly along the river Nene, on the north side, and on the western border of the Fen country.

The cathedral of St Peter is the third church that has occupied the site; the first, founded under Penda, king of the Mercians, about 656, was entirely destroyed by the Danes in 870, and the second, founded in King Edgar’s reign, was accidentally burnt in 1116. The present building, founded in the following year, was, inclusive of the west front, 120 years in building, being consecrated on the 4th of October 1237. It embraces in all, however, eight periods of construction, and in no other building can the transition be better studied through the various grades of Norman to Early English, while the later addition is an admirable example of Perpendicular.

It is as usual from east to west, and, while an increase in elegance and elaboration is observable in the later parts, the character of the earlier buildings was so carefully kept in mind that no sense of incongruity is produced. A series of uniform Decorated windows were added throughout the church in the 14th century, and their effect is rather to enhance than detract from the unity of design. The choir, early Norman, terminating in an apse, was founded in 1117 or 1118 by John de Sais or Sez, and dedicated in 1123. The transepts and the south transept were built by Martin of Bec, 1140-1155; the remaining portions of the transepts and the central tower, of three stories, were completed by William de Waterville, 1155-1175; the nave, late Norman, was completed by Abbot Ashton; the tower, a beautiful painted roof of wood; the western transepts, transitional Norman, were the work of Abbot Andrew, 1193-1200; the western front, actually a vast porics of three arches, the arches of the building, and one of the finest specimens of Early English, extant, must have been built between 1200 and 1250, during which period there were several abbeys; but there exists no record of its reconstruction. The lady chapel, built parallel with the choir by Abbot Peter, was completed by Abbot Richard between 1260 and 1274; the south-west spire, the pinnacles of the flanking tower of the west portal, and the enlargement of the windows of the nave and aisles were the work of Abbot Peter. The building of the eastern (or tower) of the new church, begun in 1266, was not completed till 1528. In 1541 the church was converted into a cathedral, the abbot being made the first bishop. The extreme length of the building is 471 ft., and of the nave 211 ft., the breadth of the west front being 156; the height of the central tower, as reconstructed in the 14th century, was 150, that of the spires and tower of the west front is 156 ft. In 1643 the building was defaced by the soldiers of Cromwell, who destroyed nearly all the brasses and monuments, burnt the ancient records, levelled the altar and screen, defaced the windows, and demolished the clavices. Some materials for repairs the lady chapel was taken down. In the latter part of the 18th century the church was repaired. In 1831 a throne, stalls and choir-screen were erected and other restorations completed. On account of the insecure state of the concordant the tower was repaired, and the spires and tower were made exactly as it stood with the exception of the four corner turrets added early in the 19th century, was completed in 1886. The choir was reopened in 1889 after being closed, to the first restoration, for 65 years.

In 1865 the restoration of the west front and other parts was begun in the face of considerable adverse criticism; but the work was carried on with the utmost care. During the carrying out of this large work, the interior of the church was made into a magnificent site; the chapel of the Church of England, enclosed within a crypt adjacent to the south transept. Catherine of Aragon was interred in the cathedral in 1536, and Mary Queen of Scots in 1587, but the body of the Scottish queen was removed to Westminster Abbey in 1612. Both interments were superintended by Robert Scarlett the sexton, commonly known as "Old Scarlett," whose portrait, a copy of the original, hangs in the west transept. He died in 1594 at the age of 96. Of the monastic buildings there are some interesting remains. The church is approached by a Norman gateway, above which is the chapel of St Nicholas, built by Abbot Benedict, and now used as the music school, and on the left the chapel of St Thomas à Becket, built by Abbot Cambridge in the 13th century as it stands, but was built again in 1895 by de Croyland, former owner of the abbey’s house, was built by Abbot Godfrey de Croyland in 1310, and the deanery gate by Abbot Kirton about 1520. One of the canony houses is formed partly from a hall of the 13th century.

Peterborough is included for civil purposes in the parish of St John the Baptist, but for ecclesiastical purposes it is divided into four, the additional parishes being St Mary’s Boongate (1857), St Mark’s (1858) and St Paul’s (1866). The old parish church of St John originally stood to the east of the cathedral, but was built on its present site in the centre of the city (1400-1407) in Perpendicular style. The educational establishments include the Henry VIII. grammar or chapter school, which used the chapel of St Thomas à Becket until 1885; the St Peter’s training college for schoolmasters for the dioceses of Peterborough, Ely and Lincoln, erected from designs of Sir Gilbert Scott (1864); and Deacon’s and Ireland’s charity school, established in 1721 for the clothing and educating of twenty poor boys. The principal public building is the market house (1671), used as a town-hall. The modern prosperity and rapid growth of the town are chiefly due to the trade caused by the junction of so many railway lines. Adjoining the town are extensive works and sheds connected with the Great Northern and Midland railways. The principal manufacture is of agricultural implements. The parliamentary borough returns one member (since 1885). The municipal borough, incorporated in 1854, is under a mayor, 6 aldermen and 18 councillors. An area of 18 square miles, comprising 2183 acres. The town or liberty of Peterborough, with a population of 41,122, constitutes a separate administrative county (1888). The diocese of Peterborough includes the whole of Rutland, nearly all Leicestershire and Northamptonshire, and small portions of Derbyshire and Huntingdonshire.

Peterborough (Burgh, Burgus sancti Petri) is proved by its original name Medehamstede to have been a Saxon village before 655 when Saxul, a monk, founded the monastery on land granted to him for that purpose by Penda, king of Mercia. Its name was altered to Burgh between 992 and 1003 after Abbot Kenulf had made a wall round the minister, but the town does not appear to have been a borough until the 12th century. The burgesses received their first charter from "Abbot Robert," probably in 1117 (Sutton 1267, 2373). The 11th century charter of 1091 which mentions the "land and liberties of the town" was granted in the name of the "town and manor, appointed a great bailiff, and the constables and other borough officers were elected at their court leet, but the borough was incorporated in 1874 under the provisions of a mayor, 6 aldermen and 18 councillors. Among the privileges claimed by the borough as early as the 13th century was that of having a prison for felons taken in the soke and borough. In 1576 Bishop Scamble sold the lordship of the hundred of Nassaburgh, which is coextensive with the soke, to Queen Elizabeth, who
gave it to Lord Burghley, and from that time until the 19th century he and his descendants, marquesses of Exeter, had a separate seat in Peterborough for prisoners arrested in the sokes. The trades of weaving and woolcombing were carried on in Peterborough in the 14th century. The abbey formerly held four fairs, of which two, one called St Peter's Fair, granted in 1189 and now held on the second Tuesday and Wednesday in July, and the other called the Bridge fair, granted in 1430 and held on the first Tuesday, Wednesday and Thursday in October, still survive and were purchased by the corporation from the ecclesiastical commissioners in 1876. Peterborough sent two members to parliament for the first time in 1547.

**PETERBOROUGH AND MONMOUTH, CHARLES MORDAUNT, EARL OF (1658-1732)**

English soldier and statesman, was born about 1658. His father, John Mordaunt, was created Viscount Mordaunt of Avalon and Baron Mordaunt of Reigate, Surrey, in 1659; his mother was Elizabeth, the daughter and sole heir of Thomas Carey, the second son of Robert Carey, 1st earl of Monmouth. He matriculated at Christ Church, Oxford, on the 11th of April 1674. When about sixteen years of age he joined Sir John Narborough's fleet in the Mediterranean, and won his first distinction in arms in the destruction of the day's fleet under the very guns of Tripoli. His father died on the 5th of June 1675, and Charles Mordaunt succeeded to the peerage as Viscount Mordaunt. On his return from the second expedition to Tangier he plunged into active political life as a zealous Whig and an unswerving opponent of the duke of York. But his continued hostility to James II. forced him to repair to Holland in 1686, when he proposed to William of Orange to invade England. The disposition of the cold and cautious William had little in common with the fierce and turbulent Mordaunt. His plan was rejected, though the prudent prince of Orange deemed it judicious to retain his services. When William sailed to Torbay his friend accompanied him, and when the Dutch prince was safely established on the throne of England honours without stint were showered upon Lord Mordaunt. He was sworn of the privy council on the 14th of February 1689, on the 8th of April of the same year appointed first lord of the treasury, and a day later advanced in the peerage by creation as earl of Monmouth.

In less than a year he was out of the treasury, but he still remained by the person of his monarch and was with him in his dangerous passage to Holland in January 1691. He was one of the eighteen peers who signed the protest against the rejection, on the 7th of December 1692, of the motion for the appointment of a committee to inquire into the conduct of the war, and although William had refused his consent to a bill for triennial parliaments in the previous session, Lord Monmouth solemnly refused to reintroduce it in December 1693. This led to a disagreement with the court, though the final breach did not take place until January 1697, when Monmouth was accused of complicity in Sir John Fenwick's conspiracy and of the use of "unfair words" towards the king. He was committed to the Tower, staying in confinement until the 30th of March 1697, and deprived of his employments. Some consolation for these troubles came to him on the 19th of June of the same year, when he succeeded to the earldom of Peterborough, by the death of his uncle Henry Mordaunt, 2nd earl.

The four years after his release from the Tower were mainly passed in retirement, but on the accession of Anne he plunged into political life again with avidity. His first act was to draw down on himself in February 1702 the censure of the House of Commons for the part which he took in the attempt to secure the renunciation of the Roman Catholic religion by Anne. Through the fear of the ministry that his restless spirit would drive him into opposition to its measures if he stayed at home, he was appointed early in 1705 to command an expedition of English and Dutch troops in Spain. He was created the sole commander of the land forces in April 1705 and joint-commander with Sir Cloudesley Shovel of the fleet on the 1st of May, after he had been reinstated a member of the privy council on the 20th of March. He arrived at Lisbon on the 20th of June 1705, sailed for Barcelona (Aug. 1705) on an expedition for the conquest of Catalonia, and began to besiege that town. For some weeks the operations were not prosecuted with vigour and Peterborough urged that the fleet should transport the troops to Italy, but the energetic counsels of the Archduke Charles at last prevailed and by the 14th of October the city fell into his hands. On the 24th of January 1706 he entered Valencia in triumph, but these movements had weakened the garrison at Barcelona, which was now besieged by a superior French force under Tésé. The garrison, commanded by the archduke, defended their positions with great bravery, but would have been obliged to surrender had not the fleet of Sir John Leake, answering the signals of Charles but contrary to the original orders of Peterborough, come to their assistance on the 8th of May, whereupon the French raised the siege on the 11th of May. It is difficult to understand the action of Peterborough during this campaign, unless on the supposition that he was out of sympathy with the movement for placing an Austrian prince on the throne of Spain. When Charles determined upon uniting with Lord Galway's troops and marching to Madrid, the advice of Peterborough again hindered his progress.

At first he urged an advance by Valencia as supplies had there been collected, then he withdrew this statement; afterwards he delayed for some weeks to join Galway, who was in need of succour, but ultimately reached the camp on the 6th of August. The leaders of the army differed in their views, and Lord Peterborough was recalled to England to explain his conduct (March 1707).

On his return to England in August he allied himself with the Tories, and received his reward in being contrasted, much to his advantage, with the Whig victor of Blenheim and Malplaquet. The differences between the three peers, Peterborough, Galway and Tyrawley, who had served in Spain, formed the subject of angry debates in the Lords, when the majority declared for Peterborough; after some fiery speeches the resolution that he had performed many great and eminent services was carried, and votes of thanks were passed to him without any division (January and February 1708). His new friends were not desirous of detaining him long on English soil, and they sent him on a mission to Vienna, where he characteristically engaged the ministry in pledges of which they disapproved. His resentment at this disagreement was softened by the command of a cavalry regiment, and by his appointment as a Knight of the Garter (Aug. 3 and 4, 1713). With the accession of George I. Lord Peterborough's influence was gone. Worn out with suffering, he died at Lisbon on the 25th of October 1735. His remains were brought to England, and buried at Turvey in Bedfordshire on the 21st of November.

Lord Peterborough was short in stature and spare in habit of body. His activity knew no bounds. He was said to have seen more kings and postillions than any man in Europe, and the whole point of Swift's lines on "Mordanto" consisted in a description of the speed with which he hastened from capital to capital. He was eloquent in debate and intrepid in war, but his influence in the senate was ruined through his inconsistency, and his vigour in the field was wasted through his want of union with his colleagues. His first wife, Carey, daughter of Sir Alexander Fraser of Dores, Kincardineshire, died on the 13th (14th) of May 1700, and was buried at Turvey. Some years later (c. 1696-1705) a famous dramatic singer (from 1714) of great beauty and sweetness of disposition, daughter of Thomas Robinson (d. 1722), a portrait painter; but she was at first unrecognized as his wife, and lived apart from him (regarded merely as his mistress) with her two sisters at Parson's Green. She remained on the operative stage, till 1724. It was only a few months before his death that (after a second marriage ceremony) she
was introduced to society as the countess of Peterborough. He had a son John (1681-1710) who predeceased him, and was therefore succeeded in the title by his grandson Charles (1710-1779), whose son Charles Henry (1758-1814), 5th earl, died unmarried, the honors becoming extinct, except for the barony of Mordaunt, which passed to a collateral branch and fell into abeyance in 1836.

Bibliography.—The best accounts of the career of Peterborough are in the life by William Stebbing (1890), and the War of the Succession in Spain, by Colonel the Hon. Arthur Parnell (1905). The earlier lives are founded on the memoir of Captain George Carleton (1728), which was analysed by Colonel Parnell, and dismissed as a fictitious narrative inspired by Swift, in the Eng. Hist. Rev. (1891), vi. 97-151.

PETERHEAD, a municipal and police burgh, and seaport of Aberdeenshire, the most easterly town in Scotland. Pop. (1901), 11,794. It is situated about 33 m. by road E.N.E. of Aberdeen and 441 m. by rail, via Maud Junction, on the Great North of Scotland railway, from which there is a branch line. The town is built of the red granite for which it is famous, and the quarrying of which for home and foreign use constitutes an important industry. Among the principal buildings are the town-house (1788), with a spire 125 ft. high, and the Arbuthnot museum and art gallery. In front of the town-hall is a statue to Field Marshal Keith (born at Inverurie Castle, 2 m. north-west, in 1666), which was presented to the burgh in 1868 by William I. of Prussia, afterwards German emperor. Peterhead is one of the Elgin district group of parliamentary burghs, with Banff, Cullen, Elgin, Inverurie and Kintore. It formerly had an extensive trade with the ports of the Baltic, the Levant and America, and was once a sub-port to Aberdeen, but was made independent in 1832. It was also for a long period the chief seat of the Greenland trade, but the Arctic seal and whale fishery is now extinct. The north and south harbours lie between the town and Keith Inch—a suburb at the extremity of the peninsula on part of which the town is built and the hinterland divided by an isthmus, crossed by an iron swing-bridge. In the north harbour are two graving docks. A third harbour has been built, the area of the three basins amounting to 21 acres. In addition to the granite quarrying and polishing, the leading industries are ship- and boat-building, agricultural implement works and woollen manufactures. The herring fleet possesses more than 600 boats and the annual catch averages nearly £200,000. About a mile to the south is the convict prison for Scotland. Since 1886 the prisoners have been employed upon the construction of a vast harbour of refuge, for which the breakwater extends from Boddam Point northwards across the bay. This great undertaking (intended to be completed in 1921) was designed by Sir John Coode (d. 1892). Peterhead is the terminus of a cable to Norway. About 6 m. south of Peterhead are the famous Bullers, or Roarers, of Buchan, an enormous rocky cauldron into which the waves pour through a natural arch of granite, with incredible violence, in a storm.

The town and lands belonged of old to the Abbey of Deer, built in the 13th century by William Comyn, earl of Buchan; but when the abbey was erected into a temporal lordship in the family of Keith the superiority of the town passed to the earl marischal, with whom it continued till the forfeiture of the earldom in 1716. The town and lands were purchased in 1720 by a fishing company in England and, on their failure, by the Merchant Maidens' Hospital of Edinburgh for £3,000, who are still the overlords. Peterhead, made a burgh of barony in 1593 by George Keith, fifth earl marischal, was the scene of the landing of the Pretender on Christmas Day 1715.

PETERHOF, a town of Russia, in the government of St Petersburg, 18 m. W. of the capital, on the south coast of the Gulf of Finland. It was founded in 1711 and has grown up round the palace built by Peter the Great in 1720; pop., 11,300. Peterhof is almost exclusively a residential town, but, among the palace and the manufacture of agricultural implements are carried on. The palace has undergone alterations and additions, e.g. by Catherine II., but retains a distinct Petrine stamp. It is built on a height 50 ft. above the sea, and contains portraits of the Russian imperial family and other pictures. A statue of Peter the Great was set up near the palace in 1882, and one of Francis I. of France in 1896, a gift from the town of Havre to Nicholas II. Peterhof is connected with Oranienbaum on the west and with Stryelna on the east by series of gardens and villas.

PETERMANN, AUGUST HEINRICH (1822-1878), German cartographer, was born at Bleicherode, near Nordhausen, on the 18th of April 1822. At the age of seventeen he entered the Geographical School of Art in Potsdam, and in 1845 proceeded to Edinburgh to assist Dr Keith Johnston in the production of an English edition of the Physical Atlas of Berghaus. In 1847 he came to London, and published among other works, an account of Barth's expedition to Central Africa (1853). In 1854 he became director of the geographical institute of Justus Perthes in Gotia, and editor of the well-known Petermanns Mitteilungen. His work did much towards elucidating the geography of the interior of Africa and of the North Polar regions. Queen Victoria, at the suggestion of Bunsen, appointed him physical geographer-royal. Petermann died by his own hand at Gotta on the 25th of September 1878.

PETERS (or Peter), HUGH (1598-1660), English Independent divine, son of Thomas Dyckwood, alias Peters, descended from a family which had quitted the Netherlands to escape religious persecution, and of Martha, daughter of John Treffry of Treffry in Cornwall, was baptized on the 29th of June 1598, and was educated at Trinity College, Cambridge. Having experienced conversion, he preached in Essex; returning to London he took Anglican orders and was appointed lecturer at St Sepulchre's. He entertained, however, unorthodox opinions, and eventually left England for Holland. He visited Gustavus Adolphus in Germany about 1632, and afterwards became the minister of the English church at Rotterdam. Here his unorthodox leanings again attracted attention, and Peters made a further escape to New England. He was converted with John Warfield through his wife, and had already formed several friendships with the American colonists. He arrived at Boston in October 1635 and was given charge of the church at Salem. He took a leading part in the affairs of the colony, and interested himself in the founding of the new colony in Connecticut. In 1641 he returned to England as agent of the colony, but soon became involved in the political troubles which now began. He became chaplain to the forces of the adventurers in Ireland, and served in 1642 in Lord Forbes's expedition, of which he wrote an account. On his return he took a violent part in the campaign against Laud, and defended the doctrines of the Independents in a preface to a tract by Richard Mather entitled "Church Government and Church Covenant discussed . . ." (1643). He gained great reputation as a preacher by his discourses and exhortations at public executions, and as army chaplain. In the latter capacity he accompanied Lord Warvick's naval expedition to Lyme in 1644 and Fairfax's campaigns of 1645 and 1646, when his eloquence is said to have had a marvellous effect in inspiring the soldiers and winning over the people. At the conclusion of the war, Peters, though greatly disliked by the Presbyterians and the Scots, had attained great influence as leader of the Independents. In his pamphlet "Last Report of the English Wars" (1646) he urged religious toleration, an alliance with foreign Protestants, and an active propagation of the gospel. In the dispute between the army and the parliament he naturally took the side of the former, and after the seizure of the king by the army in June 1647 had interviews with Charles at Newmarket and Windsor, in which he favourably impressed the latter, and gave advice upon the best course to pursue. He performed useful services in the second Civil War, procured guns for the besiegers at Pembroke, raised troops in the midlands, and arranged the surrender of the duke of Hamilton at Uttoxeter. Though at the Restoration he denied any complicity in the king's death, it is certain that in his sermons he justified and supported the trial and sentence. In August he accompanied Cromwell to Ireland, and was present at the fall of Wexford,
while later he assisted the campaign by superintending from England the despatch to Cromwell of supplies and reinforce-
ments, and was himself destined by Cromwell for a regiment of
foot. In 1650 he was in South Wales, endeavouring to over-
come the people to the cause, and subsequently was present at
the battle of Worcester. At the conclusion of the war Peters
was appointed one of the preachers at Whitehall and became a
person of influence. Parliament had already voted him an
annuity of £200, and Laud’s library or a portion of it had been
handed over to him in 1644. He was one of the committee of
twenty-one appointed to suggest legal reforms, and he published
his ideas on this subject, which included a register of wills and
land titles and the destruction afterwards of the ancient records,
in his tract, “Good Work for a Good Magistrate” (in 1651),
answered by R. Vaughan and Prymne. He strongly disapproved
of the war with Holland, and his interference brought upon
him some sharp reprimands. In July 1658 he was sent to
Dunkirk to provide apparently for the spiritual wants of the
garrison. He preached the funeral sermon on Cromwell, and
after the latter’s death took little part in political events,
though strongly disapproving of the removal of Charles. He
met Monck at St Albans on the latter’s march to London, but
met with no favour from the new powers, being expelled from
his lodgings at Whitehall in January 1660. On the 11th of
May his arrest was ordered. On the 18th of June he was ex-
cepted from the Act of Indemnity and apprehended on the 2nd
of September at Southwark. He sent in a defence of himself
to the Lords, denying any share in the king’s death. He was,
however, tried on the 13th of October and found guilty of high
treason. His execution took place at Charing Cross on the 16th
of October, when he behaved with great fortitude, and was
undismayed by the mangling of the body of John Cook, his
fellow sufferer, upon which he was forced to look. Before his
death he wrote “A Dying Father’s Last Legacy”, to his only
child, Elizabeth, in which he gave a narrative of his career.
His death was viewed with greater rejoicings than perhaps
attended that of any of the regicides, which is the more sur-
prising as Peters possessed many amiable qualities, and several
acts of kindness performed by him are on record. No Royalists are
recorded. But he had incurred great unpopularity by his
unrestrained speech and extreme activity in the cause.
He was a man, however, of a rough, coarse nature, without
tact or refinement, of strong animal spirits, undeterred by
difficulties which beset men of higher mental capacity, whose
energies often outran his discretion, intent upon the realities
of life and the practical side of religion. His conception of
religious controversy, that all differences could be avoided if
ministers could only pray together and live together, is highly
characteristic, and shows the largeness of his personal sympa-
thies and at the same time the limits of his intellectual
imagination. Peters married (1) Elizabeth, daughter of Thomas
Cooke of Pembmarsh in Essex and widow of Edmund Read,
and (2) Deliverance Sheffield, by whom he had one daughter,
Elizabeth.

PETERS, KARL (1856—) German traveller in Africa, one
of the founders of German East Africa, was born at Neuhau-
us on the Elbe on the 6th of September 1856, the son of a
clergyman. He studied at Göttingen, Tübingen and Berlin,
and in 1879 was awarded a gold medal by the Berlin University
for his Frieden zu Venedig. After visiting London to study
English principles of colonization, he returned to Berlin and
promoted the German Colonization Society (Deutsche Kolonial-
verein). In the autumn of 1884 he proceeded with two
companions to East Africa, and concluded in the name of his society
with the chiefs of Usenge, Muguru, Usagara and Ukimani.
Returning to Europe early in 1885, he formed the German East
Africa Company, which speedily obtained an imperial charter.
The story of this enterprise, the first step in the formation of a
German colony in East Africa, is told under AFRICA, § 5. In
1888 Peters undertook an expedition from the east coast of
Africa, avowedly for the relief of Emin Pasha. This expedition
was not so actioned by the British government and was regarded
by the British authorities as a filibustering exploit. One of its
objects was to extend the sphere of German influence, and, reach-
ing Uganda early in 1890, Peters concluded a treaty with the king
of that country in favour of Germany. He left Uganda hastily
on the approach of a representative of the British East Africa
Company, and on reaching Zanzibar learned that his treaty was
useless, as an agreement had been come to between Germany
and Great Britain whereby Uganda was left in the British sphere.
On his return to Germany Peters was received with great honour,
and in 1891 published an account of his expedition entitled
Die deutsche Emin Pasha Expedition, which was translated
into English. In 1891 he went out again to East Africa as
imperial high commissioner for the Kilimanjaro district, and
in 1892 was one of the commissioners for delimiting the Anglo-
German boundary in that region. In June 1892 accusations
were brought against him of excesses in his treatment of the
natives, and after three investigations had been held he was,
in 1897, deprived of his commission for “misuse of official
power.” He was regranted his title of imperial commissioner
in 1906. During 1893–1895 Peters was employed in the colonial
services in India, and in 1896 he was removed to London, where he
occupied himself in schemes for exploiting parts of Rhodesia
and Portuguese East Africa. In the interests of a company he
formed, Peters explored the Fura district and Macombe’s
country on the Zambezi, where in 1899 he discovered ruins of
ancient cities and deserted gold mines. He returned in 1901
and gave an account of his explorations in The Eldorado of
the Ancients (1902). In 1905 he again visited the region between
the Zambezi and Sabi rivers.

Besides the books already mentioned and some smaller treatises
Peters published a philosophic work entitled Willenswelt und Welt-
weise (1883), and a dissertation on early gold production entitled
Das goldenen Uphir Selomos (1893), translated into English in 1898.

PETERSBURG, a city and port of entry of Virginia, U.S.A.,
on the Appomattox river, at the head of navigation, about
11 m. from its mouth, and 22 m. S. of Richmond. Pop. (1800),
22,680; (1900), 21,810, (10,751 negroes); (1910), 24,127. It is
served by the Atlantic Coast Line, the Seaboard Air Line and the
Atlantic and Dan River railways. The river, which is here spanned
by two steel bridges and one frame bridge, is navigable to this
point for vessels of 8 ft. draught at mean high water, and has
been greatly improved by the Federal government, which in 1909
was engaged in deepening the whole channel to 12 ft. at mean
high water and in excavating at Petersburg a new channel into
which to deflect the river. In and about the city there is much
of historic and scenic interest. At Blandford, a suburban
hamlet, is the picturesque old Blandford church, erected about
1734. Petersburg has two public parks, and among its institu-
tions are a home for the sick (1886), an orphanage for girls
and another for negroes, the state central hospital for the insane
(negroes), the southern female college (non-sectarian, 1863),
the university school for boys, the Bishop Payne divinity
school (Protestant Episcopal) for negroes, and the Virginia
normal and industrial institute (opened in 1883), also for
negroes. There are two national cemeteries near Petersburg—
Poplar Grove (about 4 m. south), containing about 6,200 graves,
and City Point (about 9 m. east), containing 5,000 graves;
and in Blandford cemetery there are about 30,000 graves of
Confederate dead. In this cemetery General William Phillips is
buried, and there is a monument to Captain McRae, commander
of the “Petersburg Volunteers,” whose bravery in 1812–1813
prompted President Madison to call Petersburg the “Cockade
City.” The falls above the city furnish abundant water-power,
and the city has various manufactures. The factory product
was valued at $5,890,574 in 1905, 11.3% more than in 1900;
in both 1900 and 1905 Petersburg ranked fourth among the
cities of the state in the value of factory products. From
Petersburg are shipped quantities of trunks and bags, peanuts,
tobacco and cotton. In 1900 the foreign trade, wholly imports,
was valued at $60,774. The city was formerly in Chesterfield,
Dinwiddie and Prince George counties, but is now independent
of county government.
An Indian village formerly stood on or near the site of the present city, and Fort Henry was built here by the whites in 1844. Petersburg was founded in 1733 by Colonel William Byrd (1674–1744) and Peter Jones, and was named (first Peter's Point, and then Petersburg) in honour of the latter; in 1748 it was incorporated as a town. On the 25th of April 1781 a skirmish was fought in front of Petersburg between a British force of about 3000 under General William Phillips (1735–1781) and about one-third of that number of American militia under Baron Friedrich Wilhelm von Steuben; the Americans were defeated, and the British occupied the town. In the following month the British again entered Petersburg (General Phillips dying here on the 13th), but they were soon dislodged by Lafayette who shelled the town. General Winfield Scott was born near Petersburg, and practised law here for two years before he entered the army. Petersburg was chartered as a city in 1850.

**PETERSBURG CAMPAIGN (1864–65).** The name of Petersburg is associated with operations in the American Civil War, which formed the sequel of the Wilderness Campaign (q.v.) and the last act in the struggle between the armies of Grant and Lee for supremacy. Petersburg (see above) and Richmond, Virginia, connected by rail and covered north, east and south by forty miles of entrenchments, formed the salients of a vast fortress, into which reinforcements and supplies could be poured from the rear by means of the James Canal, the Virginia Central, the Lynchburg, the Danville and the Weldon railroads—the latter bringing up to Petersburg from Wilmington (225 m. distant) the cargoes of blockade runners. Petersburg became a strategic point as soon as Grant determined to carry the army of the Potomac—defeated at Cold Harbor on the Chickahominy (see WILDERNESS CAMPAIGN)—south of Richmond, and, being joined by Butler's Army of the James (momentarily checked in the Bermuda Hundred Peninsula by a small army under Beauregard), to operate from the east, depending on the James river, as his line of supply, while the policy of the Confederate president was to employ Robert E. Lee's army to protect his capital. Petersburg was nearer than Richmond to the navigable part of the James River—City Point is only 10 m. distant—and the capture of Petersburg would involve the fall of Richmond and the capitulation or flight of Lee's army.

As early as the 9th of June 1864, while the main armies were still north of the James and Petersburg was garrisoned by a brigade under General Wise, a Federal expedition from the Army of the James approached the city. General Gillmore on the City Point road discovered strong earthworks, and General Kautz attacking on the Jerusalem Plank road experienced a repulse, the total force of the Federals was 4500, and Wise's brigade (2400) had been quickly reinforced from Beauregard's central position at Bermuda Hundred. A week later a more serious attempt was made to break through the defences, while General Lee's main army was detainted north of Richmond. Grant detached the II. and XVIII. corps under Generals Smith and Hancock, who were to unite and operate along the City Point railroad and capture the outer line of works about 2 m. from Petersburg while a demonstration was made along the Norfolk railroad by cavalry under Kautz. On the 13th of June Smith attacked and captured five redans before Hancock came up, and when next day Burnside's corps (IX.) arrived and General Meade assumed control of the three corps, he attacked again at 6 p.m. On the 17th of June Warren's (V.) corps arrived, and Meade made a third assault with three corps (II., IX., XIX.) late in the afternoon, and the results of the four days' fighting were so far satisfactory that ground won which could be entrenched and held against any sortie of the Petersburg garrison. Probably on the 18th of June the town of Petersburg might have been captured by Meade, for at this crisis General Lee was in temporary eclipse. For four days Lee had refused to credit any report to the effect that Grant was crossing the James: his cavalry could not ascertain that the enemy in his front at Malvern Hill (VI. corps and Wilson's cavalry division), despite its menacing attitude towards Richmond, was only a flank guard for a movement to the south.

It was late on the 17th of June when General Beauregard, who had for three days valiantly held his main lines south of Richmond with some 14,000 infantry against three Federal corps, succeeded in convincing General Lee that the main army was again (as in 1862 on the Chickahominy) in the wrong place at the wrong time. But when at last the Confederate leader was aroused to a sense of his danger he soon filled every road with divisions marching to save Petersburg: they marched all night; they slept in the trenches on arrival, and on the 19th of June these reinforcements convinced General Meade that his main attack between the Appomattox river and the Jerusalem Plank road was delivered a day too late. At a cost of 10,000 casualties Meade had gained half a mile of ground, but the Confederates in falling back had concentrated, and now that the new plan of operations was exposed and the main bodies were again face to face the power of defensive tactics reasserted itself.

Yet June was not to close without adding some 8000 men to the Federal casualties, for in addition to daily losses by sharp-shooting along the front, over 3000 men fell or were captured in operations directed against the southern railroads. Grant had resolved to deprive his enemy of these lines of supply: his plan was to prolong his line of investment westward and construct redoubts (such as Fort Davis, Fort Steadman and Fort Sedgwick) as a continual menace to the Confederate garrison and a defence against sorties, while his cavalry and portions of five corps (II., V., VI., IX. and XVIII.) engaged in enterprises which it was hoped would tempt General Lee to fight outside his works. A decisive victory in the field, a successful assault on the defences between Richmond and Petersburg, or the complete destruction of the railroads, would precipitate disaster to the South, and of these three methods the last would be the surest in its effects. But such a method was necessarily slow. General Wilson's cavalry (3500) destroyed 30 m. of the Lynchburg or South Side railroad, and 30 m. of the Danville railroad, together with Burkeville Junction and Ream's Station on the Weldon railroad; but Wilson was caught by the Confederate cavalry 100 m. from Petersburg and escaped only by destroying his wagons and limbers and abandoning twelve guns. Even the Virginia Central railroad could not be held by the Federals after Sheridan with the main body of the cavalry had been called back to White House on the Pamunkey to escort a great convoy.

By the end of June the whole of the rival forces were concentrated about the Richmond-Petersburg defences, and General A. P. Hill had already sallied out on the 21st of June to drive the II. corps from the Weldon railroad. Federal policy and Federal strategy, surmounting the crisis of Cold Harbor, were, however, at last in unison. Grant had a free hand in respect both of his dispositions and his resources in men and money, and had resolved to use unsparring the resources placed at his disposal. Early in July Grant, however, found himself compelled to detach a corps (VI.) to strengthen the garrison at Washington, for General Early had frustrated Hunter's attempt against Lynchburg (see Shenandoah Valley), driving Hunter into West Virginia, and then, pushing down the Shenandoah and across the Potomac, had arrived within a day's march of the Federal capital. This operation checked Grant's enterprises about Petersburg and restricted the Federal front to the ground east of the Weldon railroad.

On the 25th of July Grant resolved to weaken the enemy on his right by a demonstration north of the James, and accordingly moved a corps (II.) and two cavalry divisions across the river to Malvern Hill under cover of Foster's corps (X.). But Lee possessed the inner line, and the Federal detachment found two cavalry divisions in its front, and the Richmond defences had been strengthened by three divisions of infantry. The expedition then returned to take part in a fresh enterprise, which ended disastrously to the Federals. A Confederate redan faced Burnside's IX. corps 100 yds. distant, and this strong work was...
PETERSBURG

302

to be destroyed by mining operations. The mine was fired and produced a crater 150 ft. long, 60 ft. wide and 25 ft. deep, into which the Federals poured (see FORTIFICATION and SIEGELRAFT). But the troops could not get no farther before the Confederate counter-attack was upon them, and Burnside’s corps lost 4300 men.

In August Sheridan was detached to operate against General Early in the Shenandoah Valley, and in order to prevent Lee reinforcing Early another demonstration against Richmond was planned. But it failed and his left and the result of the fighting was a loss to the Federals of nearly 3000 men. Meanwhile another attack on the Weldon railroad by Warren’s corps was met by General A. P. Hill on the 20th of August, and the possession of the railroad cost by Hancock’s II. corps and Gregg’s cavalry division at a point 3 m. south of Ream’s Station was foiled by A. P. Hill, now aided by Hampton’s two cavalry divisions, and the Federals here lost 2372 men and nine guns. The Confederates therefore still retained possession of the railroad to a point within one day’s hauling by wagon to Petersburg. During September another Federal enterprise north of the James with two corps (X. and XVIII.) resulted in the capture of Fort Hamrick and Chaffin’s Bluff, and when General Lee reinforced his left and counter-attacked his troops were repulsed with heavy loss. The Federals lost over 2000 men and failed in the attempt to take Fort Gilmer, Confederate gunboats below Richmond, aiding in the defence. While this operation was in progress on the Confederate left under General Grant’s personal supervision General Lee was apprised of attacks on his extreme right at Peebles Farm by four divisions, which captured a Confederate redoubt covering the junction of two routes to the south-west. General A. P. Hill ordered a further advance of the enemy by a vigorous counter-attack which caused Warren and Parke (IX.) a loss of 2000 men, of whom nearly three fourths allowed themselves to be captured; for the rank, since the losses of the May battles, had been swapped with the rear-guard and substitutes recruits of poor quality and almost insignificant training. The Federals had, however, by these operations pushed their entrenchments beyond the Weldon railroad westward and established new works within a mile of the Confederates. General Lee, after a fruitless attempt on the 7th of October between the Confederates and troops of the Army of the James was without result. At the end of the month, however, General Grant resolved to make a serious effort to bring the South Side railroad within his lines and deprive the enemy of an important line of supply. Parke (IX.), Warren (V.) and Hancock (II.) took each some 11,000 infantry with four days’ rations on pack animals. Gregg’s cavalry (3000) were attached for the operation, and both Grant and Meade found leading troops. They attacked the Confederate forces with three divisions (14,000) and Hampton’s cavalry (5500), and they contrived to hold two corps with one division and attack Hancock (II.) with his main body. The Federals were stopped when 2 m. from the railway, and Hancock lost 1500 men at Hatcher’s Run on the 27th of October.

General Lee meanwhile had been called to Chaffin’s Bluff, where again Butler was demonstrating with the Army of the James (X. and XVIII.) on the approaches to Richmond. But General Longstreet signaled his return to duty with the Army of Northern Virginia by driving Butler off with a loss of over 1000 men (action of Fair Oaks, Oct. 27). General Warren in December contrived to evade A. P. Hill and destroy the Weldon railroad at a point on the Meherrin river 40 m. from Petersburg.

There seemed now little to tie Lee to the lines he had so painfully held. Though for his army was without coffee, tea or sugar, and though of foreign meat they had 3 1/4 million rations and of bread 2 1/2 million, yet of rations in reserve, the troops lived chiefly on corn-bread. A. P. Hill on the right held on from Hatcher’s Run to Fort Gregg, whence Gordon and Anderson prolonged to the left as far as the Appomattox River, and Longstreet continued the line northwards along the Bermuda front across the James as far as White’s Swamp (37 m. in all). The winter was very severe, and the continual trench-work and outpost duty overtaxed the patriotism of Lee’s 50,000 infantry and stimulated desertion. Supplies were brought in by wagons, as the rolling stock on the railways was worn, and on the 5th of February 1865 General Gregg moved out to the Boydton plank road to intercept the Confederate convoys. He was supported by Warren, while Humphrey’s (II.) corps connected the detachment with the left of the Federal entrenchments. Gregg failed to locate the wagons, and General Lee, hearing of the expedition, sent out A. P. Hill and Gordon, who drove him back with a loss of 1500 men. Sheridan, after driving Early from the Valley in October, destroyed the railways south of Staunton, Charlottesville, Gordonsville and Lynchburg, and even rendered the James Canal useless as a line of supply. Grant recalled Sheridan to the main army in March, and at the end of the month prepared for a turning movement westward with the object of drawing Lee out of his lines. General Lee had anticipated such an attempt, and had resolved to abandon his lines and unite with Johnston in North Carolina, but the roads were not...
sly in a state for the movement of artillery and wagons, and it was not to gain time that he now ventured upon a bold offensive stroke—a night attack upon a strong point in the Federal right called Fort Steadman—the success of which might cause Grant to call in the detachments on his left and so facilitate the proposed movement of the Confederates towards Danville. General Gordon was selected to conduct the operation and his corps was strongly reinforced for the occasion. The opposing lines east of Petersburg were only 150 yds., and the streets of each at 50 yds. apart. Gordon's men dashed across the intervening space at 4:30 a.m. on the 25th March, surprised the garrison and occupied Fort Steadman, but when day broke the Federal guns could be brought to bear the fort was found to be untenable. Pickett's corps (IX.) recaptured the work at a cost of 1000 men, and Gordon fell back, leaving nearly 2000 men in the hands of the Federals. The encounter would have proved a more desperate one if reinforcements on both sides had arrived in time, but Gordon had cut the telegraph wires connecting Fort Steadman with Grant's headquarters at City Point, and the Confederate train service broke down and delayed the arrival from Richmond of reinforcements for Gordon. Meanwhile, 6 m. westward, Humphreys' corps (II.) had gained some local success, seizing the Confederate picket line between the Weldon railroad and the Boydton Plank road, which was once occupied and strengthened by the Federals. The Federals had resolved to attempt. Grant meanwhile had ordered Warren to support Sheridan in an attack on Pickett at daybreak. Sheridan advanced on the 1st of April and at 3 p.m. issued his orders for attack, explaining verbally a diagram he had prepared for the use of divisional commanders. Pickett held a front of 2 m. with a division of cavalry on either flank and Rosser's cavalry guarding the baggage behind Hatcher's Run, and when attacked at 4 p.m. he was with Rosser 3 m. in rear. Before Pickett was made aware of a battle being in progress his left was destroyed. General Lee seems to have made no arrangements to support Pickett in this direction. Pickett's right was defended by W. H. F. Lee against the attack of Custer's cavalry division. The position was lost and was carried by Sheridan's cavalry under Devin dismounting and storming the entrenchments frontally, taking three guns and 100 prisoners. Warren's corps claimed to have captured a battery and 3244 prisoners. Yet Sheridan was dissatisfied with Warren's conduct of the battle and deprived him of his command. Pickett's routed brigades were rallied at the South Side railroad and incorporated with General Anderson's command. But the Confederates, having lost White Oak road, and unless General Lee was capable of a vigorous resistance, it was evident he must also lose the South Side railroad. Grant, fearing such an enterprise, at once reinforced Sheridan and ordered Humphreys' corps (II.) to attack in his front if necessary to prevent Lee moving troops westward, but Lee made no effort, and so Sheridan was free to operate farther in the direction of the enemy's right and rear, while Humphreys held the enemy in his front. Sheridan remained inactive for a few days, and Lee hoped still to gain time for the roads to be evacuated, his lines and removing his stores and ammunition by wagons towards Lynchburg.

Yet a crisis was approaching. Sheridan's success at Five Forks induced Grant to deliver a general assault on the 2nd of April. The Confederate lines were broken all night, and on the 2nd of April, with Wright's corps (VI.), Grant attacked the weakest part of Lee's line and broke through, losing 1100 men in fifteen minutes. A. P. Hill was killed and his corps broke and was cut off from Petersburg. At the same time Parke's corps (IX.), on the right of the VI., attacked the eastern front near Fort Steadman but was repulsed by General Gordon; then Humphreys' corps (II.) on the left attacked a Confederate division under General Cook and forced it to retreat to the South Side railroad. Here at South Hampton, a final attack dispersed it. Wright, supported by General Ord (commanding the army of the James), afterwards won the strong redoubts called Fort Whitworth and Fort Gregg, and thus in a day the Confederate army was cut in two or three miles west of the Weldon railroad; 10 m. of works had been abandoned, and if Grant had been able to press his advantage once the campaign must have ended. But Grant was not aware of Lee's plight, so resolved to wait until the morrow before completing his victory.

Meanwhile Lee perceived that the hour had come at last when Richmond must fall, and at 3 p.m. he had issued orders for the march of his right to Lynchburg via Amelia Court House, a march which evidently must partake of the character of a forlorn hope, hastily planned, ill prepared for by the troops whom the disasters and hardships of the past six months had weakened the army's back to the guns on the 2nd of April military history would have lost of the finest examples of the strategic pursuit. Lee's proposed movement involved the transfer of the army and its baggage 100 m. on roads across the front of enemy, and nothing but mischance could prevent the Federals intercepting Lee's column by a shorter route and seizing the South Side railroad, on which supplies
were to be forwarded from Lynchburg to meet the retreating army at Appomattox Station, Pamplin's Station or Farmville Station. The Appomattox River must be crossed two or three times at its bends. Various creeks and swamps must be bridged, and the bridges destroyed. The roads leading to the bridges were crossed by early morning roads so as to be covered by the columns during marches and combats and the infantry were to follow the artillery on the roads. Longstreet, Gordon and Malbone's division from Richmond all crossed the small stream and joined the corps on the way to Appomattox by the Danville railroad bridge north of Goode's Bridge. Anderson commanded the flank guard which moved south of the Appomattox with Fitzhugh Lee's cavalry. Lee gained a day's start in crossing the railroad bridge before the corps could attack the entrenchments next day (April 3), but the start was lost in waiting for President Davis and the government to escape from Richmond. Sheridan's cavalry got in touch with Lee's flank guard early this morning at 6 a.m. and the corps was attacked nightfall by the Federal advance-guard was at Deep Creek. On the 4th of April Sheridan reached the Danville railroad at Jetersville, and on the 5th of April, when Lee had halted at Amelia Court-House on the approach of Sheridan's army (Longstreet, V.I.), the corps in support of Sheridan 8 m. nearer to Lee than to Sailor's Creek, the point where he must again cross the Appomattox.

Interception was now a fait accompli, though neither side suspected it. Lee was unaware of the enemy's proximity, and Grant believed that Lee would remain at Amelia Court-House, but Lee moved west, crossing Flat Creek at sunset on the 5th of April, to the Lynchburg railroad (Longstreet, marching all night, reached Rice's Station at seven o'clock next morning). His column covered a distance of 38 miles on the same day to attack Lee at Amelia Court-House, and on discovering Lee's evasion the three Federal corps effected a wheel to the right and an enveloping movement on Deatonsville hill over the bridge Flat Creek. Meanwhile the Federal cavalry under H. E. Davies had located Lee's rearguard at Paynsville, dispersed its escort (Gary's cavalry) and burned the wagons, but had in turn been attacked by Fitzhugh Lee's cavalry at Amelia Springs and driven back on the main body at Flat Creek. Fitzhugh Lee's rear guard then fell on the rearguard of the Federal cavalry, The rearguard of Lee's army was Gordon's command, which was at Amelia Springs after Ewell's command had passed through at 8 a.m. on the 6th of April. Lee's army stretched out for 15 m., and while its advance-guard was at Radical Station it was suspected in all directions. Meanwhile Sheridan had crossed Flat Creek, and nightfall had lost the Federal advance-guard was at Deep Creek. On the 4th of April Sheridan reached the Danville railroad at Jetersville, and on the 5th of April, when Lee had halted at Amelia Court-House on the approach of Sheridan's army (Longstreet, V.I.), the corps in support of Sheridan 8 m. nearer to Lee than to Sailor's Creek, the point where he must again cross the Appomattox.

Complete disorganization and demoralization seem to have taken hold of the Confederates on this fatal day, and General Lee was once more in eclipse. The Federal cavalry headed the column, the infantry attacked it, and Ewell became the victim of tactical confusion. Sheridan had been defeated and Gordon had failed to save the trains of the army. Surrender or massacre being the alternatives, Ewell surrendered, and here in fact is the career of the army of Northern Virginia ended, as Grant plainly saw, for at 5 p.m. he addressed a demoralizing order. But Lee clung to his diminished forces for another 48 hours. Longstreet in crossing at Farmville had burnt the bridges and thus delayed Ord in pursuit; but Gordon and Mahone, who had crossed at Ewell's head, and the 25th and 30th Virginia and 2nd and 3rd Maryland corps (II.) and were compelled to take up a position on the north bank until darkness enabled them to slip away. General Lee was with this remnant of the army. Meanwhile Sheridan with the three Federal corps of Longstreet and Gordon, engaged in the South Side railroad, seizing the supplies waiting for Lee at Pamplin's Station, and then moving on another 12 m. to Appomattox Station. At nightfall he found that he was astride the enemy's line of operation, which ran through the head of the Apalachee River. Lee would be compelled to give battle or capitulate on the morrow.

General Lee, quitting Farmville heights on the night of the 7th of April changed the order of march during the next day, so that Gordon (8000, with two Federal corps (II.) and 4th South Carolina) was guar. Ewell's corps was now represented by 300 effective. The cavalry still numbered some 1600 sabres. Lee's column was pursued along the Lynchburg Road by two Federal corps (II.), which had marched 18 miles, and 3 m. of Longstreet, who had entrenched near Appomattox Court-House, facing east and covering the road on which Gordon's corps and the cavalry was to press forward to Lynchburg at daylight. But Gordon on the morning of the 9th. Lee had three brigades in his front, and in accordance with plans made over night he commenced an attack, driving the Federals back until he encountered at 10 a.m. two corps of infantry (V., XXIV.) under General Ord, who had marched 29 m. in order to support Sheridan at the crisis; and when at the same moment Longstreet was threatened by Humphreys and Wright (II., VI.) the situation had arisen which General Lee feared. The two Federal corps, columns of wagons, and 25,494 enlisted men were paroled, all that remained in the field of some 55,000 Confederates who were drawing rations on the 20th of February as the army of Northern Virginia.

PETERSFIELD, a market town in the Petersfield parlia-
mentary division of Hampshire, England, 55 m. S.W. from London by the London & South Western railway. Pop. of urban district (1901), 3265. The church of St Peter retains some ornate Norman work. The picturesque market-place contains an equestrian statue of William III.

Laterally a chapel of Burton-on-Trent, Petersfield (Peterfield) owes its origin as a borough to the charter granted by William, earl of Gloucester, in the reign of Henry II., and confirmed later by his widow, Hawke. Petersfield is not mentioned in Domesday, but it was probably then included in the manor of Mapledurham. It was a mesne borough possessing by its first charter the liberties and customs of Winchester together with a merchant guild. These grants were confirmed by John in 1198 and in 1315 Henry V. in addition freed the burgesses from all tolls. No charter of incorporation has been found. Gradually privileges and rights other than those of a mesne borough were usurped by the mayor and burgesses, but were recovered by a suit brought against them by Thomas Hanbury, owner of the borough, in 1611. A mayor continued to be elected until 1885. Petersfield was represented in parliament in 1307. No returns were made for 1555-1553, from which the two members were regularly returned. In 1832 the number was reduced to one, and in 1885 the representation was merged in that of the county. Three-day fairs at the feasts of St Peter and St Andrew were granted in 1255. In 1837 the summer fair then held on the 10th of July was abolished. The autumn fair now held on the 6th of October is for both business and pleasure. The market, which dates from before 1373, formerly held on Saturday, is now held on alternate Wednesdays.

In the 16th century Petersfield had important cloth and leather manufactures.

Peter's Pence, Rome Scot, or Rome-Foo, a tax of a penny on every hearth, formerly paid annually to the popes; now represented by a voluntary contribution made by the devout in Roman Catholic churches. Its date of origin is doubtful. The present written evidence of it is contained in a letter of Canute (1031) sent from Rome to the English clergy. At this time it appears to have been levied on all families possessed of land worth thirty pence yearly rental, out of which they paid one penny. Matthew Paris says the tax was instituted by Offa, king of Mercia (757-796) for the upkeep of the English school and hostel at Rome. Layamon, however, declares that Ilna, king of Wessex (688-725), was the originator of the idea. At the Norman Conquest it appears to have fallen into arrears for a time, for William the Conqueror promised the pope in 1076 that it should be regularly paid. By a bull of Pope Adrian IV. the tax was extended to Ireland. In 1213 Innocent III. complained that the bishops kept 1000 marks of it, only forwarding 300 to Rome. In 1306 Clement V. exacted a penny from each household instead of the 50s. at which the tax appears to have been then fixed. The threat of withholding Peter's pence proved more than once a useful weapon against recalcitrant popes in the hands of English kings. Thus in 1366 and for some years after it was refused on the ground of the pope's abjuration in withholding his consent to the statute of praemunire. In the 16th century Peter's pence was introduced into Poland, Prussia and Scandinavia, and in the 17th century Gregory VII. attempted to exact it from France and
Spain. The tax was fairly regularly paid by the English until 1534, when it was abolished by Henry VIII.

**Peterwardein** (Hung. Petővariad, Serv. Petrovaradin), a royal free town and fortress of Hungary in the county of Syrmia, Croatia-Slavonia; situated on a promontory formed by a loop of the Danube, 62 m. N.W. of Belgrade by rail. Pop. (1900), 5019. It is connected with Neusatz on the opposite bank by a bridge of boats, a railway bridge and a steam ferry. The fortifications consist of the upper fortress, on a lofty serpentine rock rising abruptly from the plain on three sides, and of the lower fortress at the northern base of the rock. The two fortresses can accommodate a garrison of 10,000 men. In the lower fortress is the town, with a military hospital, and an arsenal containing trophies captured from the Turks. Peterwardein, the "Gibraltar of Hungary," is believed to represent the Roman *Acumenum*, and received its present name from Peter the Hermit, who here in 1096 marshalled the levies of the first crusade. It was captured by the Turks in 1526 and retained by them for 160 years. In 1716 it witnessed a signal defeat inflicted on the Turks by Prince Eugène. During the revolutionary struggles of 1848-49 the fortress was held by the insurgents for a short time.

**Peterkirk, John** (1813-1882). Welsh traveller in East Central Africa, born in Glamorganshire, and adopted the profession of mining engineer. In 1845 he entered the service of Mehemet Ali, and was employed in examining Upper Egypt, Nubia, the Red Sea coast and Kordofan in an unsuccessful search for coal. In 1848 Peterkirk left the Egyptian service and established himself at El Obeid, the capital of Kordofan, as a trader, dealing largely in gum arabic. He was at the same time made British consular agent for the Sudan. In 1853 he removed to Khartoum and became an ivory trader. He travelled extensively in the Bahr-el-Ghazal region, then almost unknown, exploring the Jur, Yalo and other affluents of the Ghazal. In 1858 he penetrated to the Niam-Niam country. His additions to the knowledge of natural history were considerable, among his discoveries being the *Cobus maris* (Mrs Gray's waterbuck) and the *Balaneus rex* (white-headed stork). Peterkirk returned to England in 1859 where he made the acquaintance of J. H. Speke, then arranging for his expedition to discover the source of the Nile. While in England Peterkirk married, and published an account of his travels. He returned to the Sudan in 1861, accompanied by his wife and with the rank of consul. He was entrusted with a mission by the Royal Geographical Society to convey to Gondokoro relief stores for Captains Speke and Grant. Peterkirk got boats to Gondokoro in 1862, but Speke and Grant had not arrived. Having arranged for a native force to proceed south to get in touch with the absentees, a task successfully accomplished, Mr and Mrs Peterkirk undertook another journey in the Bahr-el-Ghazal, making important collections of plants and fishes. They regained Gondokoro (where one of their boats with stores was already stationed) in February 1863, four days after the arrival of Speke and Grant, who had meantime accepted the hospitality of Mr (afterwards Sir) Samuel Baker. The charge that Peterkirk failed to meet his engagement was baseless, and even then he had been censured and even taken part in the slave trade was subsequently shown to have no foundation (Peterkirk in fact had endeavoured to stop the traffic), but it led Earl Russell, then secretary for foreign affairs, to abolish the British consulate at Khartoum (1864). In 1865 the Peterkirs returned to England, and in 1866 published *Travels in Central Africa and Explorations of the Western Nile Tributaries*, in which book are set out the details of the Speke controversy. Peterkirk died in London, on the 15th of July 1882.

**Pétion de Villeneuve, Jérôme** (1756-1794). French writer and politician, was the son of a procureur at Chartres. He became an avocat in 1778, and at once began to try to make a name in literature. His first printed work was an essay, *Sur les moyens de prévenir l'infanticide*, which failed to gain the prize for which it was composed, but pleased Brissot so much that he printed it in vol. vii. of his *Bibliothèque philosophique* de législateurs. Pétion's next works, *Les Lois civiles, and Essais sur le mariage*, in which he advocated the marriage of priests, confirmed his position as a bold reformer, and when the elections to the States-General took place in 1789 he was elected a deputy to the Tiers État for Chartres. Both in the assembly of the Tiers État and in the Constituent Assembly Pétion showed himself a radical leader. He supported Mirabeau on the 23rd of June, attacked the queen on the 5th of October, and was elected president on the 4th of December 1790. On the 15th of June 1791 he was elected president of the criminal tribunal of Paris. On the 21st of June 1791 he was chosen one of three commissioners appointed to bring back the king from Varennes, and he has left a fatuous account of the journey. After the last meeting of the assembly on the 30th of September 1791 Robespierre and Pétion were made the popular heroes and were crowned by the populace with civic crowns. Pétion received a still further proof of the affection of the Parisians for himself on the 16th of November 1791, when he was elected second mayor of Paris in succession to Bailly. In his majority he exhibited clearly his republican tendency and his hatred of the old monarchy, especially on the 20th of June 1792, when he allowed the mob to overrun the Tuileries and insult the royal family. For neglecting to protect the Tuileries he was suspended from office in June 1793. When the fall of the Girondins, the Jacobins rose to power, and the leaders of the Legislative Assembly felt that Pétion's cause was theirs, and rescinded the suspension on the 13th of July. On the 3rd of August, at the head of the municipality of Paris, Pétion demanded the dethronement of the king. He was elected to the Convention for Eure-et-Loir and became its first president. L. P. Manuel had the folly to propose that the president of the Assembly should have the same authority as the president of the United States; his proposition was at once rejected, but Pétion got the nickname of "Roi Pétion," which contributed to his fall. His jealousy of Robespierre allied him to the Girondin party, with which he voted for the king's death and for the appeal to the people. He was elected in March 1793 to the first Committee of Public Safety; and he attacked Robespierre, who had accused him of having known and having kept secret Dumouriez's project of treason. His popularity however had waned, and his name was among those of the twenty-two Girondin deputies proscribed on the 2nd of June. Pétion was one of those who escaped to Caen and raised the standard of provincial insurrection against the Convention; and, when the Norman rising failed, he fled with M. E. Guadet, F. A. Buzot, C. J. M. Bararoux, J. B. Salle and Louvet de Couvrai to the Gironde, where they were sheltered by a wig-maker of Saint Émilion. At last, a month before Robespierre's fall in June 1794, the escaped deputies felt themselves no longer safe, and deserted their asylum; Louvet found his way to Paris, Salle and Guadet to Bordeaux, where they were soon taken; Bararoux committed suicide; and the bodies of Pétion and Buzot, who also killed themselves, were found in a field, half-eaten by wolves.

**Pétis de la Croix, François** (1653-1713). French Orientalist, was born in Paris in 1653. He was son of the Arabic interpreter of the French court, and inherited this office at his father's death in 1695, afterwards transmitting it to his own son, Alexandre Louis Marie, who also distinguished himself in Oriental studies. At an early age he was sent by Colbert to the East; during the ten years he spent in Syria, Persia and Turkey he mastered Arabic, Persian and Turkish, and also collected rich materials for future writings. He served a short time as secretary to the French ambassador in Morocco, and accompanied as interpreter the French forces sent against Algiers, contributing to the satisfactory settlement of the treaty of peace, which was drawn up by himself in Turkish and ratified in 1684. He conducted the negotiations with Tunis and Tripoli.
in 1685, and those with Morocco in 1657; and the zeal, tact and linguistic knowledge he manifested in these and other transactions with Eastern courts were at last rewarded in 1692 by his appointment to the Arabic chair in the Collège Royal de France, which he filled until his death in 1713.

He published *Contes turcs* (Paris, 1707), and *Les Mille et un jours* (3 vols., Paris, 1710-1712); an Armenian Dictionary and an Account of Eastern Languages are also included in his *Histoire de l'histoire*, one of the most important French versions of Sharaf-ud'din *Ali Yazdi's Zaifarnama* or *History of Timur* (completed 828 A.H.; A.D. 1425), which was given to the world nine years after his death (4 vols., Paris, 1722; Eng. trans. by J. Darby, London, 1723).

This work, one of the rare specimens of a fairly critical history, Persia catalogued, in was compiled under the auspices of Mirza Ibrahim Sultan, the son of Shah Rukh and grandson of the great Timur. The only error committed by Pétis de la Croix in his otherwise very correct translation is that he erroneously ascribed the important share which Ibrahim Sultan had in the *Zaifarnama* to Timur himself.

PETIT, SIR DINSHAW MANECKJI, Bart. (1823-1901), Parsee philanthropist, was born on the 30th of June 1823. As broker to European firms he amassed a large fortune during the period of speculation in Bombay at the time of the American Civil War. In 1886 he became a member of the governor-general's legislative council. He devoted his wealth to philanthropic objects, among the public and private charities which he endowed being the Towers of Silence and the Jamshedji Poonawala Institute for the Education of Indians and Indians for Indians. He established a hospital, an institution for animals, a college for women, and the Petit hospital. He was knighted in 1887, created a baronet in 1890, and died in February 1901.

PETIT DE JULLEVILLE, LOUIS (1841-1900), French scholar, was born in Paris on the 18th of July 1841. Educated at the École Normale Supérieure, and at the French school at Athens, he received his doctorate in literature in 1868. After holding various posts as a teacher he became professor of French medieval literature and of the history of the French language in the university of Paris in 1886. He died on the 28th of August 1900.

His most important works are: Histoire du théâtre en France, including Les Mystères (2 vols., 1880); Les Comédies en France au moyen âge (1884); La Comédie et ses Maîtres en France au moyen âge (1886); Répertoire du théâtre comique en France au moyen âge (1888); and Le Théâtre en France, histoire de la littérature dramatique depuis ses origines jusqu'à nos jours (1886). Petit de Julleville was also the general editor of the Histoire de la langue et de la littérature française (8 vols., 1896-1900), to which he himself contributed some valuable chapters.

**PETITION** (Lat. for "seeking" or "praying"), a term meaning generally a prayerful request, and in its more important constitutional aspect an application for redress by a person aggrieved, or to invoke the public sympathy or to relieve him. It may be made in the United Kingdom to the Crown or its officers, or to either house of parliament, or in certain cases to courts of justice.

**Petitions to the Crown.**—The right of petitioning the Crown was recognized indirectly as early as Magna Carta in the famous clause, *Nulli vendemus, nullo negabimus aut differemus, rectum vel jactitiam* (25 Edw. I. c. 29), and directly at various periods later, e.g. in the articles of the Commons assented to by Henry IV., by which the king was to assign two days in the week for petitions (Rot. Parl. 8 Hen. IV., p. 585). The case of the seven bishops in 1688 confirmed the right, and finally the Bill of Rights in 1689 declared "that it is the right of the subjects to petition the king, and all commitments and prosecutions for such petitioning are illegal. Petitions to the Crown appear to have been at first for the redress of private and local grievances, or for remedies which the courts of law could not grant (May, Parl. Pr., 11th ed., 352). As equity grew into a system, petitions of this kind not seeking legislative remedies tended to become superseded by bills in chancery. Statutes were originally drawn up by the judges at the close of the session of parliament from the petitions of the Commons and the answers of the Crown. Under this system of drafting it was found that the tenor of the petition and answer were not always stated correctly. To obviate this inconvenience demands for legislation came in the reign of Henry VI. to be drawn up in the form of bills which the Crown could accept or reject, but could not alter (see Anson, *Law and Custom of the Constitution*, 3rd ed., vol. i. p. 241). In the same reign the words "by authority of parliament" were added to the words of enactment, and from the time of Henry VII. public legislation has been by bill and not by petition. A relic of the old form of statute founded upon petition still remains however in the preamble of Appropriation Acts and other statutes creating a charge upon the public revenue. It runs thus: "We, your majesty's most dutiful and loyal subjects, the Commons of the United Kingdom . . . do most humbly beseech your majesty that it may be enacted; and be it enacted," &c., from this point following the enacting words common to all statutes. The Crown may refer petitions presented to it to be adjudicated upon by a delegated authority. This course is pursued in the case of claims to peerages and offices of honour, which are referred to the House of Lords, and by that house to its committee for privileges, and in the case of petitions to the Crown in similitudinem, which are usually referred to the judicial committee. The Crown may delegate the power of receiving petitions in the first instance.

**Petitions to Parliament.**—Petitions to either house of the legislature seem to have been later in origin than petitions to the Crown. They are not referred to in the Bill of Rights, but the right of petition is a convention of the constitution. Petitions to the Lords or the whole parliament can be traced back to Henry III. No petition to the Commons has been found earlier than Richard II.; but from the time of Henry IV. petitions to the Commons have been freely made. The political importance of petitioning dates from about the reign of Charles I. The development of the practice of petitioning had proceeded so far in the reign of Charles II. as to lead to the passing in 1662 of an act (13 Car. II. c. 5) against "tumultuous petitioning," which is still on the statute book. It provides that no petition or address shall be presented to the king or either house of parliament by more than ten persons; nor shall any one procure above twenty persons to consent or set their hands to any petition for alteration of matters established by law in church or state, unless with the previous order of three justices of the county, or the major part of the grand jury. And in 1817 (37 Geo. III. c. 19, s. 23) meetings within a mile from Westminster Hall for the purpose of considering a petition to both houses or either house of parliament while either house is sitting were declared to be unlawful assemblies. Up to 1688 petitions to either house usually dealt only with some specific grievance. From that time dates the present practice of petitioning with regard to general measures of public policy. Petitions to the Houses of Lords or Commons must be framed in the form prescribed by the standing orders, must be properly superscribed, and must conclude with a prayer (May, Parl. Pr., 11th ed., 351). They may be sent free by post to members of either house if they fulfil certain conditions as to weight, &c. (loc. cit. p. 531). Petitions to the Commons must be in writing, must contain none but genuine signatures, and must be free from disregardful language or imputations upon any tribunal or constituted authority. They must be presented by a member of the house, except petitions to the House of Commons from the corporation of London, which may be presented at the bar by the sheriffs, and from the corporation of Dublin, which may be presented by the lord mayor. There is no means of compelling a member to present a petition. The rules as to petitions to the House of Lords are similar. The lord who presents a petition is required to read it to see whether in form and contents it is fit for presentation. In the Lords receivers and triers of petitions from Great Britain and Ireland and from Gascogne and the lands and countries beyond the sea were appointed until 1886, though their functions had long been obsolete. Applications for leave to bring before either house bills for private or local and personal matters must under the standing orders of both houses be made in the form of bills, by petitions or special rules as to applications for leave to be heard in opposition to such bills.

**Petitions to Courts of Justice.**—Strictly speaking, these are an indirect mode of petitioning the Crown, for in the theory of English law the Crown is the fountain of justice. But it is more convenient to treat them separately, as they now form a part of the practice of the courts. Appeals to the House of Lords and the privy council are prosecuted by petition of appeal. The
PETITIO PRINCIPII
307
original jurisdiction of the privy council to deal with petitions is confined to proceedings under certain statutes, such as the Enrolled Schools Acts, the Public Schools Acts, the Universities Acts and the Patents Acts. In most cases the petitions are referred to the judicial committee of the council. Petitions may be addressed to the lord chancellor in a few instances, e.g. for the removal of coroners or county court judges. The House of Lords at one time claimed original jurisdiction in civil and criminal matters. As to civil matters the claim is abandoned; as to criminal matters it is now limited to impeachment for crime by the Commons on the trial for treason or felony of persons having privilege of peerage.

The most important use of petitions in England is in the High Court of Chancery. Chancery division petitions are presented either as interlocutory proceedings in the course of an action, or as original proceedings where no litigation exists—being a more speedy form of remedy than an action. The cases in which a petition is admissible and the way of therein, are in the main regulated by orders 52 and 55 of the rules of the supreme court. Evidence in support of petitions is usually by affidavit. Petitions in the course of an action are presented to the court in which the action is brought. Examples of original petitions are those under the Lands Clauses Acts, the Trustee Acts and the Companies Acts. For many proceedings under these acts a simpler and cheaper form of proceeding by summons has been substituted for that by petition. The Chancery Division is the successor to the Equity jurisdiction under the Chancery division as successor to the court of chancery. Petitions are also in use in other courts having equitable jurisdiction, e.g. the chancery courts of the counties palatine of Lancaster and Ulster and the special courts for cases falling within § 2 of the County Courts Act 1888, and as to cases within county court jurisdiction under the Settled Land Acts or the Guardianship of Infants Act 1886 (County Court Rules, O. 38). In a few cases petitions are presented to the House of Commons, by way of parliamentary intervention, under the Trusts Act 1860. In the king's bench division the only use of petitions appears to be to initiate proceedings in bankruptcy. Leave to sue in forma pauperis used to be given on petition but is now confined to bankruptcy proceedings. Proceedings in matrimonial causes, &c., are begun by petition, but the course of the proceedings closely resembles those of an ordinary action.

Scotland.—In Scotland petitions in the Court of Session are either original or in a pending action. Original petitions are presented to one of the divisions of the inner house, unless they relate to matters mentioned in 20 & 21 Vict. c. 56, s. 4, where they are brought before the lords of session as an alternative to the court of session. The court, by a recent amendment (17 & 18 Vict. c. 23), may, with the consent of the parties, refer the case to the sheriff of the county to reframe the issue. Where there is no such consent, the case is heard by the sheriff and may be brought before the court of session for a second hearing, or the memorial is referred to the court of session. The declaration of the court of session is final in the absence of a suit brought in the court of session, and the sheriff is bound to comply with the act of the court of session. The court of session may frame a new declaration, and the sheriff is bound to comply with the act of the court of session.

Ireland.—The law of Ireland as to petitions is in substance the same as that in Scotland, as to the cases in which petitions may be made to courts of justice.

United States.—In the United States before the Civil War questions arose as to the right of petitioning Congress, particularly with reference to petitions for the restriction of slavery which at that time was contended to be a matter of state and not of federal concern (see Cooley, Constitutional Limitations, 6th ed., 1890, 426). The right of the petitioning the United States government is now secured by the amendment to the constitution adopted in 1865, and the right to petition the president of the United States for redress of grievances is specifically guaranteed in the first amendment to the constitution (1789-1791), which provides that “Congress shall make no law... abridging... the right of the people peaceably to assemble, and to petition the government for a redress of grievances.” In view of the Supreme Court this amendment gives recognition to the existence of the right of the people to assemble for lawful purposes and protects it against encroachment by Congress. The right was not created by the amendment; neither was it a consequence of the continual grants of power to Congress to the states. The right of the people to petition for a redress of grievances was thus given recognition, since without the power to seek redress of grievances the states could be made subject to the dictates of the national government an attribute of national citizenship, and as such under the protection of and guaranteed by the United States. The very idea of a government republican in form that imposes duties on the part of certain citizens to get peaceably for consultation in respect to public affairs and to petition for a redress of grievances "(U.S. v. Cruikshank, 1875; 92 U.S. 542, 552).

A Bill of Rights is incorporated in the constitutions of many states of the Union, and is made part of the supreme law of the states (see Hough, American Constitutions, ii. 571). Petitions can be presented to the federal or state courts of justice under much the same circumstances as in England. It is a general rule in such cases that an affidavit should be made that the facts therein stated are true as far as known to petitioner and that the facts which he states as knowing from others he believes to be true "(Bouvier, Law Dict.).

British Possessions.—There is a right of petition to the king for the redress of grievances in matters of decision (in matters criminal or civil) of courts of justice in the Channel Islands or Isle of Man, and in all other parts of the empire outside the British islands and of British courts in foreign countries. This right is cut down by imperial or colonial acts. The subject of the present paper, therefore, lies in the case of Canada, the subject of the present paper, is Tarring, Law Relating to Colonies (3rd ed., 1906) c. v.

The term Petition of Right, in English law, is used in two senses. (1) It denotes the statute of 1625 (3 Car. I. c. 1), a parliamentary declaration of the liberties of the people. (2) It also and more usually is employed to describe a mode of prosecuting a claim by a subject against the Crown, said to owe its origin to Edward I. Petition of right in this sense lies (a) to obtain restitution of real or personal property of the subject which has found its way into the hands of the Crown, or compensation if restitution cannot be made; (b) to recover damages for breach of a contract made on behalf of the Crown, whether the breach is due to the acts or the omissions of servants of the Crown. Where the Crown is in default of such duties as are imposed on it by statute, and where the justice of the application appears by record, as by inquest of office, the remedy is somewhat different and is called monstros ans de droit. Petition of right does not lie in respect of engagements in the naval, military or civil service of the Crown, which are as a general rule made “during pleasure,” nor for breach of public duty, e.g. failure to perform treaty obligations, nor for trespass or negligence or other torts by Crown servants. Where such acts are wrongful the remedy is by action against the official as an individual and not in his official capacity (Raleigh v. Goschen, 1868, L.R. 1 ch. 73).

The procedure on a petition of right is either at common law or by statute. At common law the petition went through its earliest stages in the chancery. It suggests such a right as controverts the king's right to dispose of his property (see Socius, "petition de droit fai part de l'autre." Thereupon a commission is issued to inquire into the truth of the suggestion. After the return to the commission, the attorney-general pleads or demurs, and the merits are then determined as in actions between subject and subject. If the right be determined against the Crown, judgment of amovens manus is given in favour of the supplant. The Petition of Right Act 1860 (23 & 24 Vict. c. 34, extended to Ireland in 1873, 36 & 37 Vict. c. 40, extended to Scotland in 1875, 38 & 39 Vict. c. 83, in most cases under the common law, but gives an alternative remedy. The procedure is regulated by the act of 1860, and as to England also by rules made under that act on the 1st of February 1862. The petition is left with the secretary of state for the department in which the business of whose majesty, who if he thinks fit grants his fiat that right be done. The fiat is sealed in the home office and issued to the supplant who files it in the central office of the High Court of Justice, and a sealed copy is served to the solicitor to the trust with a demand for a plea or answer on behalf of the Crown. The subsequent proceedings including those as to disclosing relevant documents are assimilated as far as possible to those in an ordinary action. A judgment in favour of the supplant is equivalent to a judgment of amovens manus ouster le main. Costs are payable to and by the Crown. A petition of right is usually tried in the chancery or king's bench divisions; but where the subject-matter of the case is peculiar to the circuit, it may be tried in the king's bench divisions of any court, or in the circuit. Petitions of right under the act of 1860 even when they are not so intimated (27 & 28 Vict. c. 25, s. 52).

The law as to petition of right applies to Ireland but not to Scotland, and a right to present such a petition appears to exist in colonies whose law is based on the common law of England. But in many colonies legislation has been passed with respect to suits against government which makes it unnecessary to resort to a petition of right.

PETITIO PRINCIPII, or BÉGGING THE QUESTION (Gr. τὸ ἐν ἄρχῃ λαμβάνω, τὸ ἐν ἁρχῇ αἰτεῖαν), in logic, the fourth of Aristotle's fallacies έξ θέματος ή ἐξ αἴρεσιν. Strictly this fallacy belongs to the language of dispute. When the questioner seeks (petit) to get his adversary to admit the very matter in question. Hence the word princiopium gives a wrong impression, for the fallacy consists not in seeking for the
admission of a principle which will confute the particular proposition—a perfectly legitimate form of refutation—but in hurling the adversary into confessing the contradictory. In the ordinary use, however, "begging the question" consists in assuming in the premises the conclusion which it is desired to prove.

PETITOT, JEAN (1608–1691), French-Swiss enamel painter, was born at Geneva, a member of a Burgundian family which had fled from France on account of religious difficulties. His father, Fauille, was a wood-carver; his mother's name was Étienne Royeuse. Jean was the fourth son, and was apprenticed to a jeweller goldsmith named Pierre Bordier, with whom he struck up a close friendship. The two friends, dissatisfied with the progress they made in Geneva, went into France, and after working for a while with Toupin came to England with letters of introduction to Turquet de Mayern, physician to Charles I., who presented them to the king, for whom they made a St George for the badge of the order and carried out many commissions for portraits; amongst others preparing two large ones representing Rachel de Ruvigny, countess of Southampton, now at Chatsworth, and Mary Villiers, duchess of Richmond and Lennox, dated 1643, at one time in the possession of the Crown and now in the Pierpont Morgan collection. On the execution of the king, Petitot left England with his niece, Anne Bordier, and Bordier, being left in the lurch and carrying out certain important commissions for Cromwell and the parliament. On reaching Paris, Petitot entered into partnership with a goldsmith, Jacques Bordier, a cousin of Pierre, and it seems probable from recent research in contemporary documents that the enamel portraits attributed to Petitot were really the work of the two partners collaborating, the actual drawing being the work of Petitot, while for the enamel process Bordier was mainly responsible. The two painters were given apartments in the Louvre, received numerous commissions from Louis XIV., and painted portraits of almost every person of importance in his brilliant court. The friendship between the two lasted for thirty-five years, and was only put an end to by Bordier's death. The enamellers rendered special political services in France for the republic of Geneva, and were practically regarded as the official representatives of the republic, receiving warm thanks from the Syndics for their diplomatic work. On the revocation of the Edict of Nantes, 1685, pressure was brought to bear upon Petitot that he should change his religion. The king protected him as long as possible, and when he was tried the same year his wife, Anne Bordier, sent Bordier, bishop of Meaux, to convince the old man of the error of his ways. Eventually, in poor health and great despair, Petitot placed his signature to an act of abjuration, and Louis XIV., unwilling to acknowledge the true reason for the imprisonment of Petitot and for his liberation, informed one of his sons, who came to thank him for the pardon given to his father, that he was willing to fall in for once with "the whim of an old man who desired to be buried with his ancestors." In 1687 therefore Petitot left Paris to return to Geneva, and, after a long and tedious inquiry, was absolved by the consistory of the church of Geneva from the crime of which they considered he had been guilty, and received back to the Huguenot communion in the church of St Gervais. In Geneva he received a very important commission from John Sobieski, king of Poland, who required portraits of himself and his queen. This was followed by numberless other commissions which the painter carried out. He died of paralysis on the 3rd of April 1691, while in the very act of painting on the enamel a portrait of his faithful wife.

Petitot married in 1651 Marguerite Cuper, and Jacques Bordier married in the same year his younger sister Anne Madeleine. He had seventeen children, and for their benefit wrote out a little octavo volume containing some genealogical information, two delightful portraits, one of himself and one of his wife, and many pages occupied with prayers, meditations and religious advice. He also prepared a second manuscript volume of prayers and meditations for the use of his family, and from these two books and the records of the Huguenot societies of France and England information has been obtained respecting the painter and his family.

Of the works of Petitot the most important collection is in the Jones Bequest at the Victoria and Albert Museum. There are many in the Louvre, sixteen at Chantilly, seventeen at Windsor, and others in the collections of Earl Beauchamp, the duke of Rutland, the duke of Richmond, the earl of Dartrey, Mr Alfred de Rothschild and the late Baronesse Burdett-Coutts. Amongst Lord Dartrey's examples are portraits of Petitot and of his son, and two of the wife of Jean Petitot the younger. A second portrait of the elder Petitot is known in the Huguenot collection of the late Mr Stroehlin of Geneva. In Mr Pierpont Morgan's collection there are many exceedingly fine examples, but especially three drawings on paper, the only three which appear to have survived, and the large signed miniature of the Duchess of Richmond already mentioned, the largest work Petitot ever executed save the one at Chatsworth.

PETITOT, JEAN LOUIS (1652–c. 1730), French enamel painter, was the eldest son of Jean Petitot (q.v.), and was instructed in enamelling by his father. Some of his works so closely resemble those of the elder Petitot that it is difficult to distinguish between them, and he was really the only serious rival his father ever had. He settled for a while in London, where he remained till 1682, and painted many enamel portraits of Charles II. In 1671, Charles II. and his brother James II. were back again in London, where he remained until the time of his death.

His portrait by Mignard is in the museum at Geneva, and another by himself in the collection of the earl of Dartrey, who also owns two of his wife, Madeleine Bordier, whom he married in 1683. Another portrait believed to represent him is in the collection of Mr Pierpont Morgan.

PETITS-CHEVAUX (Fr. for "little horses"), a gambling game played with a mechanical device consisting of a board perforated with a number of concentric circular slits, in which revolve, each independently on its own axis, figures of jockeys on horseback, distinguished by numbers or colours. The bystanders having staked their money according to their choice on a board marked in divisions for this purpose, the horses are started revolting rapidly together by means of mechanism attached to the board, and the horse which stops nearest a marked goal wins, every player who has staked on that horse receiving so many times his figure on the board. In this game, horses sometimes take the place of horses. In recent years there has been a tendency to supplant the petits chevaux at French resorts by the boule or ball game, on the same principle of gambling; in this a ball is rolled on a basin-shaped table so that it may eventually settle in one of a number of shallow cups, each marked with a figure.

PETO, SIR SAMUEL MORTON, Bart. (1809–1888), English contractor, was born at Woking, Surrey, on the 4th of August 1809, and was at an early age apprenticed to his uncle, a London builder, who on his death in 1830 bequeathed the business to Peto and another nephew, Thomas Grissell. The partnership between Peto and Grissell lasted till 1846, amongst the many London buildings erected by the firm being the Reform Club, the Lyceum and St James's theatres, and the Nelson column. Peto afterwards entered into partnership with Edward Ladd Betts (1815–1872), and between 1846 and 1872 Messrs Peto & Betts carried out many large railway contracts at home and abroad, notably the more important portions of the South-Eastern and of the London Chatham & Dover lines, and, in conjunction with the artist brothers, the lines in Canada, and the London Tilbury & Southend railway. In 1854–1855 Peto and Brassey constructed a railway in the Crimea between Balaklava and the British entrenchments before Sebastopol, charging the British government only the actual out-of-pocket expenses, and for his services in this matter Peto was in 1855 made a baronet. Peto entered parliament as a Liberal in 1847, and, with a few years' interval, continued there till 1868, when, his firm having been compelled to suspend payment in the financial crisis of 1866, he was forced to resign his seat, though both Mr Disraeli and Mr Gladstone publicly eulogized his personal character. He died on the 13th of November 1889.
PETŐFI, Alexander (1823-1849), Hungarian lyric poet, was born at Kis-Körösbó, Pest county, on New Year's Day, 1823. The family received its diploma of nobility from the emperor Leopold in 1688, but the ultra-patriotic Alexander early changed the old family name, Petöfi, which pointed to Carpathian origin, into the purely Magyar form of Petőfi. The lad's early days were spent at Fegyéváza and Szabadzállás, the most Hungarian parts of Hungary, where he got most of his early education, including a good grounding in Latin. German he learnt subsequently at Pesth, and French he taught himself. He began writing verses in his twelfth year, while a student at the Aszódi gymnasium, where he also displayed a strong predilection for the stage, to the disgust of his rigorous father, who formally disowned his son, early in 1839, for some trifling peccadillo, and whose tyrannical temperament became downright furious when a series of misfortunes ruined him utterly in 1840. For the next three years Petőfi led the wretched life of a strolling player, except for a brief interval when, to escape starvation, he enlisted as a common soldier in an infantry regiment. During the greater part of 1842 we find him a student at the Calvinist College at KCsopo, where he also wrote the poem “Borozó,” which the great critic Bajza at once inserted in the leading literary review, the Athenaeum (May 22, 1842). In November of the same year the restless poet quitPápa to join another travelling troupe, playing on one occasion the Fool in King Lear, and after wandering all over Hungary and suffering incredible hardships, finally settled down at Pesth (1844), where for a time he supported himself by all sorts of literary hack-work. Nevertheless, in the midst of his worst privations he read voraciously, and was at this time profoundly influenced by the dominant Romanticism of the day; while, through Tieck, he learnt to know and value the works of Shakespeare. His first volume of original poems was published in 1844 by the Society Nemzeti Kör, through the influence of the poet Vörösmarty, when every publisher had refused his MS., and the seventy-five florins which he got for it had become a matter of life or death to him. He now became a regular contributor to the leading papers of Pesth, and was reconciled to his parents, whom he practically supported for the rest of their lives out of his literary earnings. His position, if not exactly brilliant, was now at least secure. The little volume published by the Nemzeti Kör was followed by the parody, A Helyég Szalapácsa (1845); the romantic epic Jásos Vízés (1844); Cipripésmohék Eleké Sirjánd, a collection of passionate elegies over his lost love, Etelcé Csapó (1845); Ulí Jegyzetek, an imitation of Heine’s Reisebilder (1845); Szerelmék Gyongyei (1845); Ferék (1846); Szerelme és házassága (1846), and many other volumes. The first edition of his collected poems appeared in 1847. Petőfi was not yet twenty-five, and, despite the protests of the classicists, who regarded him with cold dislike, the best heads in Hungary, poets like Vörösmarty and critics like Szemere, already paid him the homage due to the prince of Magyar lyrical poets. The great public was enthusiastic on the same side, and posterity, too, has placed him among the immortals. Petőfi is as simple and genuine a poet of nature as Wordsworth or Christian Winther, and his erotic, inspired throughout by a noble idealism, have all Byron’s force and fervour, though it is perhaps in his martial songs that Petőfi’s essentially passionate and defiant genius asserts itself most triumphantly. On the 8th of September 1847 Petőfi married Julia Szendrey, who bore him a son. When the revolutionary war broke out, he espoused the tenets of the extreme democratic faction with a heat and recklessness which estranged many of his friends. He took an active part in the Transylvanian campaigns of the heroic Bem; rose by sheer valour to the rank of major; was slain at the battle of Segesvár (July 31, 1849), and his body, which was never recovered, is supposed to have been buried in the common grave of the fallen heroes in the churchyard of Fehéregyháza. The first complete edition of Petőfi’s poeticallyedited poems appeared in 1874. The best critical edition is that of Haras, 1894. There are numerous indifferent German translations.

See Ferenczi, Petőfi Életrajza; Fischer, Petőfi’s Leben und Werke (R. N. B.)

PETŐFI—PETRA

PETŐFI, Alexander

PETSKOY. a city and the county-seat of Emmet county, Michigan, U.S.A., on Little Traverse Bay, an arm of Lake Michigan, at the mouth of Bear Creek, in the north-west part of the lower peninsula. Pop. (1890), 2872; (1900), 5285, of whom 299 were foreign-born; (1910), 4775. It is served by the Pere Marquette and the Grand Rapids & Indiana railways and by steamboat lines to Chicago, Detroit, Buffalo and other lake ports. Bear Creek furnishes considerable water-power, and among the manufactures are lumber, paper, leather and foundry and machine-shop products. Petoskey was settled about 1874, was incorporated as a village in 1879, was chartered as a city in 1895, and in 1902 replaced Harbor Springs as county-seat. It was named after an Ojibwa Indian chief.

PETRA (Pērēa = the rock), a ruined site, 30° 10' N. and 35° 31' E., lying in a basin among the mountains which form the eastern flank of Wadi el-arâbâ, the great valley running from the Dead Sea to the Gulf of ‘Aqabâ. The descriptions of Strabo (xvi. p. 770), Pliny (N. H. vi. 32) and other writers leave no doubt as to the identity of this site with the famous capital of the Nabataeans (q.v.) and the centre of their caravan trade. Walled in by towering rocks and watered by a perennial stream, Petra not only possessed the advantages of a fortress but controlled the main commercial routes which passed through it to Gaza in the west, to Bostra and Damascus in the north, to Elath and Laced Comé on the Red Sea, and across the desert to the Persian Gulf.

From the 'Arâbâ travellers approach by a track which leads round Jebel Hârân (Mt Hor) and enters the plain of Petra from the south; it is just possible to find a way in from the high plateau on the north; but the most impressive entrance is from the east, down a dark and narrow gorge, in places only 10 or 12 ft. wide, called the Siq, i.e. the shaft, a split in the huge sandstone rocks which serves as the waterway of the Wadi Mûšû. Near the end of the defile stands the most elaborate of the ruins, el-Hazne or the Treasury of Pharaoh, not built but hewn out of the cliff; a little farther on, at the foot of the mountain called el-Nejtr, an amphitheatre, opens its gates, placed so as to bring the greatest number of tombs within view; and at the point where the valley opens out into the plain the site of the city is revealed with striking effect. Almost enclosing it on three sides are rose-coloured mountain walls, divided into groups by deep fissures, and lined with rock-cut tombs in the form of towers. The stream of Wadi Mûšû crosses the plain and disappears among the mountains opposite; on either bank, where the ground is fairly level, the city was built, covering a space of about 1½ sq. m. Among the ruins on the south bank stand the fragments of a temple called Kašir Fir'âun of late Roman date; just beyond this rises a rocky height which is usually regarded as the acropolis.

A position of such natural strength must have been occupied early, but we have no means of telling exactly when the history of Petra began; the evidence seems to show that the city was of relatively late foundation, though a sanctuary (see below) may have existed there from very ancient times. This part of the country was assigned by tradition to the Horites, i.e. probably "cave-dwellers," the predecessors of the Edomites (Gen. xvi. 6, xxxvi. 20-30; Deut. ii. 12); the habit of the original natives may have influenced the Nabataean custom of burying the dead and offering worship in half-excavated caves.

But that Petra itself is mentioned in the Old Testament cannot be affirmed with certainty; for though Petra is usually identified with Sela 2 which also means "a rock," the reference in Judges i. 36; Isa. xvi. 1, xlii. 17; Obad. 3, is far from clear. 2 Kings xiv. 7 seems to be more explicit; in the parallel passage, however, Sela is understood to mean simply "the rock" (z Ker. xxv. 12, see LXX). Hence many authorities doubt whether any town named Sela 3 mentioned in the Old Testament is what, then, did the Semitic

1 Buhl, Gesch. der Edomiter (1893), p. 52.
inhabitants call their city? Eusebius and Jerome (Onom. sacr. 286, 71, 145, 9, 228, 55, 287, 94), apparently on the authority of Josephus (Ant. iv. 7, 1; 4, 7), assert that Rekem was the native name. But in the Aramaic versions Rekem is the name of Kadesh; Josephus may have confused the two places. Sometimes the Aramaic versions make the form Rekem-Geya, which recalls the name of the village El-ji, south-east of Petra; the capital, however, would hardly be defined by the name of a neighbouring village. The Semitic name of the city, if it was not Sela', must remain unknown. The passage in Diodorus Siculus (xix. 94-97) describes the expeditions which Antigonus sent against the Nabataeans in 312 B.C. is generally understood to throw some light upon the history of Petra, though it must be admitted that the el-Hejr referred to as a natural fortress and place of refuge cannot be a proper name, and the description at any rate leaves that the town was not yet in existence. Brunnnow thinks that the "rock" in question was the sacred mountain en-Nejr (above); but Buhl suggests a conspicuous height about 16 m. north of Petra, Shobak, the Mont-royal of the Crusaders. More satisfactory evidence of the date at which the earliest Nabataean settlement began is to be obtained from an examination of the tombs. Two types may be distinguished broadly, the Nabataean and the Graeco-Roman. The Nabataean type starts from the simple pylon-tomb with a door set in a tower crowned by a parapet ornament, in imitation of the front of a dwelling-house; then, after passing through various stages, the full Nabataean type is reached, retaining all the native features and at the same time exhibiting characteristics which are partly Egyptian and partly Greek. Of this type there exist close parallels in the tomb-towers at el-Hejr in north Arabia, which bear long Nabataean inscriptions, and so supply a date for the corresponding monuments at Petra. Then comes a series of tomb-fronts which terminate in a semicircular arch, a feature derived from north Syria, and finally the elaborate façades, from which all trace of native style has vanished, copied from the front of a Roman temple. The exact dates of the stages in this development cannot be fixed, for strangely enough few inscriptions of any length have been found at Petra, perhaps because they have perished with the stucco or cement which was used upon many of the buildings. We have, then, as evidence for the earliest period, the simple pylon-tombs, which belong to the pre-Hellenic age; how far back in this stage the Nabataean settlement goes we do not know, but not farther than the 6th century B.C. A period follows in which the dominant civilization combines Greek, Egyptian and Syrian elements, clearly pointing to the age of the Ptolemies and Seleucids. Toward the close of the 2nd century B.C. both the Ptolemaic and Seleucid kingdoms were equally depressed, the Nabataean kingdom came to the front; under Aratus III. Phillelhenes, c. 85-60 B.C., the royal coins begin; at this time probably the theatre was excavated, and Petra must have assumed the aspect of a Hellenistic city. In the long and prosperous reign of Aratus IV. Philadæus, 9 B.C.-A.D. 40, the fine tombs of the el-Hejr type may be dated, perhaps also the great High-place. Then the city became more and more Romanized. In A.D. 106, when Cornelius Palma was governor of Syria, "Arabia belonging to Petra," was absorbed into the Roman Empire, and the native dynasty came to an end. But the city continued to flourish. It was visited in A.D. 131 by Hadrian, and stamped Adrianopolis Petra on its coins in gratitude for the emperor's benefactions; the superb Æneas, probably a temple for the worship of Isæus, and the Dēr, which resembles the Hasmonean in design, belong to this period. A century later, in the time of Alexander

Severus (A.D. 222-235), when the city was at the height of its splendour, the issue of coinage comes to an end, and there is no more building of sumptuous tombs, owing apparently to some sudden catastrophe, such as an invasion by the neo-Persian power under the Sassanid dynasty. Meanwhile as Palmyra (fl. A.D. 130-270) grew in importance and attracted the Arabian trade away from Petra, the latter declined; it seems, however, that it had lingered on as a religious centre; for we are told by Epiphanius (c. A.D. 315-403) that in his time a feast was held there on the 27th of December in honour of the virgin Chabou and her offspring Dusares (Haer. 51).

The chief god of Petra was Dhu-sharāt (Δουαράς), i.e. the lord or owner of Sharāt; he was worshipped under the form of a black rectangular stone, a sort of Petraean Kaʻaba (Suidas Lex. s.v. θεὸς Ἀρμ, and cf. Epiph. above). Associated with Dhu-sharāt was Allāt, the chief goddess of the ancient Arabs. Sanctuary chambers may be seen at various points in the site of Petra, and many places of sacrifice open to the sky are met with among the tombs, marked by remains of altars. But most eminent of all was the great High-place which has recently been discovered on en-Nejr (or Zibb 'atāf). It consists of a rock-hewn altar of burnt-offering with a place for killing the victims beside it and a shallow court, perhaps intended to hold water, in front: the most complete specimen of an ancient Semitic sanctuary that is known. Not far off are two obelisks cut out of the solid rock which has been removed to the level of their bases; these were either idols of Dhu-sharāt and Allāt, or more probably designed to mark the limits of the harmān of the sanctuary. West of the obelisks are three other places of sacrifice; and on the rocks below worshippers have carved their names (CFS. 282, 287, 289). En-Nejr, with its theatre at its foot, must have been the sacred mountain, the original sanctuary of Petra, perhaps the "very high mountain of Arabia called Dusār after the god Dusares" referred to by Steph. Byz. (s.v. Δουαράς). Christianity found its way into Petra in early times; Athanasius mentions a bishop of Petra (Ἱερού τῆς Ἀραβίας, ad Amphil. 10) named Asterius; at least one of the tombs (the "tomb with the urn") was used as a church; inscriptions in red paint records its consecration "in the time of the most holy bishop Jason" (A.D. 447). The Christianity of Petra, as of north Arabia, was swept away by the Mahomedan conquest in A.D. 632-634. Under the Latin kingdom Petra was occupied by Baldwin I. and formed the second see of the barony of Krak with the title Château de la Vallée de Moyse or Sela; it remained in the hands of the Franks till 1189; fragments of the Crusaders' citadel are still standing near the High-place on en-Nejr.

The ruins of Petra were an object of curiosity in the middle ages and were visited by the Sultan Bībars of Egypt towards the close of the 13th century. The first European to describe them was Burckhardt (1812). All former descriptions are now superseded by the magnificent work of Brünnow and Domaszewski, Die Provinz Arabiā (1904), who have minutely surveyed the whole site, classified the tombs, and compiled the accounts of earlier investigations; and by the independent researches of Dalman, Petra und seine Felshügelämmer (1908), and of Musil, Araba Petraea (1907-1908).

The Corpus Inschr. Sem. ii. 305 sqq., should be consulted, and the descriptions in Baederker-Socin's Palestina (7th edition), and René Réau for 1897, 1898, 1903.

(G. A. C.)

PETRARCH (1304-1374). Francesco Petrarca, the great Italian poet and first true reviver of learning in medieval Europe, was born at Arezzo on the 20th of July 1304. His father Petracco held a post of notary in the Florentine Rolls Court of the Riformagion; but, having espoused the same cause as Dante during the quarrels of the Blacks and Whites, Petracco was expelled from Florence by that decree of the 27th of January 1302 which confined Dante to lifetime exile. With his wife he

The whole range in which Petra lies is called Jebel esh-Sharāt, but it is doubtful whether the name of the god was derived from that of the mountain, see Ed. Meyer, loc. cit. p. 268 and Cooke, NSI. p. 218. The name is mentioned by E. L. Wilson (1891), rediscovered by G. L. Robinson (1900), described by S. I. Curtis, P. E. F. Q. S. 1900, and Savignac, Rev. bibl. (1903); with full plan and photographs.
took refuge in the Ghibelline township of Arezzo; and it was here, on the very night when his father, in company with other members of the White party, made an unsuccessful attempt to enter Florence by force, the Francesco first saw the light. He did not remain long in his birthplace. His mother, having obtained permission to return from banishment, settled at Incisa, a little village on the Arno above Florence, in February 1302. Here Petrarch spent seven years of boyhood, acquiring that pure Tuscan idiom which afterwards he used with such consummate mastery in ode and sonnet. Here too, in 1307, his brother Gherardo was born. In 1312 Petrarch set up a house for his family at Pisa; but soon afterwards, finding no scope there for the exercise of his profession as jurist, he removed them all in 1313 to Avignon. This was a step of no small importance for the future poet-scholar. Avignon at that period still belonged to Provence, and owned King Robert of Naples as sovereign. But the papacy had made it their residence after the insults offered to Boniface VIII. at Anagni in 1303. Avignon was therefore the centre of that varied society which the high pontiffs of Christendom have ever gathered round them. Nowhere else could the youth of genius who was destined to impress a cosmopolitan stamp on medieval culture and to begin the modern world have grown up under conditions more favourable to his task. At Incisa and at Pisa he had learned his mother-tongue. At Carpentras, under the direction of Convennole of Prato, he studied the humanities between the years 1315 and 1319. Avignon, at a distance from the party strife and somewhat parochial politics of the Italian commonwealths, impressed his mind with an ideal of civility raised far above provincial prejudices.

Petrarch's real name according to Tuscan usage was Francesco di Petrarca. But he altered this patronymic, for the sake of euphony, to Petrarca, proving by this slight change his emancipation from usages which, had he dwelt at Florence, would most probably have been imposed on him. Petrarca was so very anxious that his eldest son should become an eminent jurist that he sent him at the age of fifteen to study law at Montpellier. Like Ovid and many other poets, Petrarca felt no inclination for his father's profession. His intellect, indeed, was not incapable of understanding and admiring the majestic edifice of Roman law; but he shrank with disgust from the illiberal technicalities of practice. There is an authentic story of Petrarca's flinging the young student's books of poetry and rhetoric upon the fire, but saving Virgil and Cicero half-burned from the flames at his son's passionate entreaties. Notwithstanding Petrarca's firm determination to make himself a scholar and a man of letters rather than a lawyer, he so far submitted to his father's wishes as to remove about the year 1323 to Bologna, which was then the headquarters of juristic learning. There he stayed with his brother Gherardo until 1326, when his father died, and he returned to Avignon. Banishment and change of place had already diminished Petrarca's fortune, which was never large; and a fraudulent administration of his estate after his death left the two heirs in almost complete destitution. The most precious remnant of Petrarca's inheritance was a MS. of Cicero. There remained no course open for him but to take orders. This he did at once on his arrival in Provence; and we have good reason to believe that he advanced in due time to the rank of priest. A great Roman noble and ecclesiastic, Giacomo Colonna, afterwards bishop of Lombez, now befriended him, and Petrarca lived for some years in partial dependence on this patron.

On the 6th of April 1337 happened the most famous event of Petrarca's history. He saw Laura for the first time in the church of St Clara at Avignon. Who Laura was remains uncertain still. That she was the daughter of Audibert de Noves and the wife of Hugh de Sade rests partly on tradition and partly on documents which the abbé de Sade professes to have copied from originals in the 18th century. Nothing is now extant to prove that, if this lady really existed, she was the Laura of the Canzoniere, while there are reasons for suspecting that the abbé was either the fabricator of a romance flattering to his own family, or the dupe of some previous impostor. We may, however, reject the sceptical hypothesis that Laura was a mere figment of Petrarca's fancy; and, if we accept her personal reality, the poems of her lover demonstrate that she was a married woman with whom he enjoyed a respectful and not very intimate friendship.

Petrarch's inner life after this date is mainly occupied with the passion which he celebrated in his Italian poems, and with the friendships which his Latin epistles dimly reveal to us. Besides the bishop of Lombez he was now on terms of intimacy with another member of the great Colonna family, the cardinal Giovanni. A German, Ludwig, whom he called Socrates, and a Roman, Lello, who received from him the classic name of Laelius, were among his best-loved associates. Avignon was the chief seat of his residence up to the year of 1333, when he became restless and undertook his first long journey. On this occasion he visited Paris, Ghent, Liége, Cologne, making the acquaintance of learned men and copying the manuscripts of classical authors. On his return to Avignon he engaged in public affairs, pleaded the cause of the Scaligers in their lawsuit with the Rossi for the Lordship of Parma, and addressed two poetical epistles to Pope Benedict XII., upon the restoration of the papal see to Rome. His eloquence on behalf of the tyrants of Verona was successful. It won him the friendship of their ambassador, Azzo di Correggio—a fact which subsequently influenced his life in no small measure. Not very long after these events Petrarch made his first journey to Rome, a journey memorable from the account which he has left us of the impression he received from its ruins.

It was some time in the year 1337 that he established himself at Vaucluse and began that life of solitary study, heightened by communion with nature in her loneliest and wildest moods, which distinguished him in so remarkable a degree from the common herd of medieval scholars. Here he spent his time partly among books, meditating on Roman history, and preparing himself for the Latin epic of Africa. In his hours of recreation he climbed the hills or traced the Sorgues from its fountain under those tall lime-trees beside which his name was still connected with his learned impressions from his memory to paper. We may also refer many of his most important treatises in prose, as well as a large portion of his Latin correspondence, to the leisure he enjoyed in this retreat. Some woman, unknown to us by name, made him the father of a son, Giovanni, in the year 1337; and she was probably the same who brought him a daughter, Francesca, in 1343. Both children were afterwards legitimated by papal bulls. Meanwhile his fame as a poet in the Latin and the vulgar tongues steadily increased, until, when the first draughts of the Africa began to circulate about the year 1339, it became manifest that no one had a better right to the laurel crown than Petrarch. A desire for glory was one of the most deeply-rooted passions of his nature, and one of the points in which he most strikingly anticipated the humanistic scholars who succeeded him. It is not, therefore, surprising to find that he exerted his influence in several quarters with the view to obtaining the honours of a public coronation. The result of his intrigues was that on a single day in 1340, the 1st of September, he received two invitations, from the university of Paris and from King Robert of Naples respectively. He chose to accept the latter, journeyed in February 1341 to Naples, was honourably entertained by the king, and, after some formal disputations on matters touching the poet's art, was sent with magnificent credentials to Rome. There, in the month of April, Petrarch assumed the poet's crown upon the Capitol from the hand of the Roman senator amid the plaudits of the people and the patricians. The oration which he delivered on this occasion was composed upon these words of Virgil:

"Se me Parnassi deserta per ardua dulcis
Rapat amor."
PETRARCH

the foundations of his own tyranny in that city. He invited Petrarch to attend him when he made his triumphal entry at the end of May; and from this time forward for a considerable period Parma and Vaucluse were the two headquarters of the poet. The one he called his Transalpine, the other his Cisalpine

Parnassus. The events of the next six years of his life, from May 1341 to May 1347, may be briefly recapitulated. He lost his old friend the bishop of Lombez by death and his brother Gerardo by the entrance of the latter into a Carthusian monastery. Various small benefices were conferred upon him; and repeated offers of a papal secretariaship, which would have raised him to the highest dignities, were made and rejected. Petrarch remained true to the instinct of his own vocation, and had no intention of sacrificing his studies and his glory to ecclesiastical ambition. In January 1343 his old friend and patron Robert, king of Naples, died, and Petrarch was sent on an embassy from the papal court to his successor Joan. The notices which he has left us of Nepolitan society at this epoch are interesting; and, it was now, perhaps, that he met Boccaccio for the first time. The beginning of the year 1345 was marked by an event more interesting in the scholar's eyes than any change in dynasties. This was no less than a discovery at Verona of Cicero's Familiar Letters. It is much to be regretted that Petrarch found the precious MS. so late in life, when the style of his own epistles had been already modelled upon that of Seneca and St Augustine.

In the month of May 1347 Cola di Rienzi accomplished that extraordinary revolution which for a short space revived the republic in Rome, and raised this enthusiast to titular equality with kings. Petrarch, who in politics was no less visionary than Rienzi, hailed the advent of a founder and deliverer in the self-styled tribunal. Without considering the impossibility of restoring the majesty of ancient Rome, or the absurdity of dignifying the medieval Roman rabble by the name of Populus Romanus, he threw himself with passion into the republican movement, and sacrificed his old friends of the Colonna family to what he judged a patriotic duty.

Petrarch built himself a house at Parma in the autumn of 1347. Here he hoped to pursue the tranquil avocations of a poet honoured by men of the world and men of letters throughout Europe, and of an idealistic politician, whose effusions on the questions of the day were read with pleasure for their style. But in the course of the next two years this agreeable prospect was overclouded by a series of calamities. Laura died of the plague on the 6th of April 1348. Francesco degli Albizzi, Mainardo Accursio, Roberto de'Bardi, Sennuccio del Bene, Luchino Visconti, the cardinal Giovanni Colonna and several other friends followed to the grave in rapid succession. All of these had been intimate acquaintances and correspondents of the poet. Friendship with him was a passion; or, what is more true perhaps, he needed friends for the maintenance of his intellectual activity at the highest point of its effectiveness. Therefore he felt the loss of these men acutely. We may say with certainty that Laura's death, accompanied by that of so many dear friends, was the turning-point in Petrarch's inner life. He began to think of the meaning of the world, and considered a plan for establishing a kind of humanistic conven, where he might dedicate himself, in the company of kindred spirits, to still severer studies and a closer communion with God. Though nothing came of this scheme, a marked change was henceforth perceptible in Petrarch's literary compositions. The poems written In morte di Madonna Laura are graver and more religious tone. The prose works touch on retrospective topics or deal with subjects of deep meditation. At the same time his renown, continually spreading, opened to him ever fresh relations with Italian despots. The noble houses of Gonzaga at Mantua, at Carrara at Padua, of Este at Ferrara, of Malatesta at Rimini, of Visconti at Milan, vied with Azzo di Correggio in entertaining the illustrious man of letters. It was in vain that his correspondents pointed out the discrepancy between his professed zeal for Italian liberties, his recent enthusiasm for the Roman republic, and this alliance with tyrants who were destroying the freedom of the Lombard cities. Petrarch remained an incurable rhetoric-ian; and, while he stigmatized the despots in his ode to Italy and in his epistles to the emperor he accepted their hospitality. They, on their part, seem to have understood his temperament, and to have agreed to recognize his political theories as of no practical importance. The tendency to honour men of letters and to patronize the arts which distinguished Italian princes throughout the Renaissance period first manifested itself in the attitude assumed by Visconti and Carraresi to Petrarch.

When the jubilee of 1350 was proclaimed, Petrarch made a pilgrimage to Rome, passing and returning through Florence, where he established a firm friendship with Boccaccio. It has been well remarked that, while all his other friendships are shadowy and dim, this one alone stands out with clearness. Each of the two friends had a distinguished personality. Each played a foremost part in the revival of learning. Boccaccio carried his admiration for Petrarch to the point of worship. Petrarch repaid him with sympathy, counsel in literary studies, and moral support which helped to elevate and purify the younger poet's over-sensuous nature. It was Boccaccio who in the spring of 1351 brought to Petrarch, then resident with the Carrara family at Padua, an invitation from the seignory of Florence to accept the rectorship of their recently founded university. This was accompanied by a diploma of restoration to his rights as citizen and restitution of his patrimony. But, flattering as was the offer, Petrarch declined it. He preferred his literary leisure at Vaucluse, at Parma, in the courts of princes, to a post which would have brought him into contact with jealous priors and have reduced him to the position of the servant of a commonwealth. Accordingly, we find him journeying again in 1351 to Vaucluse, again refusing the office of papal secretary, again planning visionary reforms for the Roman people, and beginning that curious fragment of an autobiography which is known as the Epistle to Postierity. Early in 1353 he left Avignon for the last time, and entered Lombardy by the pass of Mont Genèvre, making his way immediately to Milan. The archbishop Giovanni Visconti was at this period virtually despot of Milan. He induced Petrarch, who had long been a friend of the Visconti family, to establish himself in his court, where he found employment for him as ambassador and orator. The most memorable of his diplomatic missions was to Venice in the autumn of 1353. Towards the close of the long struggle between Genoa and the republic of St Mark the Genoese entreated Giovanni Visconti to mediate on their behalf with the Venetians. Petrarch was entrusted with the office; and on the 8th of November he delivered a studied oration before the doge Andrea Dandolo and the great council. His eloquence had no effect; but the orator entered into relations with the Venetian aristocracy which were afterwards extended and confirmed. Meanwhile, Milan continued to be his place of residence. After Giovanni's death he remained in the court of Bernabò and Galeazzo Visconti, closing his eyes to their cruelties and exactions, serving them as a diplomatist, making speeches for them on ceremonial occasions, and partaking of the splendid hospitality they offered to emperors and princes. It was in this capacity of an independent man of letters, highly placed and free from the weight of courts and emperors, that he addressed epistles to the emperor Charles IV. upon the united state of Italy, and entreated him to resume the old Gibelline policy of Imperial interference. Charles IV. passed through Mantua in the autumn of 1354. There Petrarch made his acquaintance, and, finding him a man unfit for any noble enterprise, declined attending him to Rome. When Charles returned to Germany, after assuming the crowns in Rome and Milan, Petrarch addressed a letter of vehement invective and reproach to the emperor who was so negligent of the duties imposed on him by his high office. This did not prevent the Visconti sending him on an embassy to Charles in 1356. Petrarch found him at Prague, and, after pleading the cause of his masters, was despatched with honour and the diploma of count palatine. His student's life at Milan was again interrupted in 1356 by a mission on which Galeazzo Visconti sent him to King John of France. The tyrants of Milan were aspiring to royal alliances; Gian Galeazzo Visconti had been married to Isabella of France;
Vioante Visconti, a few years later, was wedded to the English duke of Clarence. Petrarch was now commissioned to congratulate King John upon his liberation from captivity to England. This duty performed, he returned to Milan, where in 1361 he received news of the deaths of his son Giovanni and his old friend Socrates. Both had been carried off by plague.

The remaining years of Petrarch's life, important as they were for the furtherance of humanistic studies, may be briefly condensed. On the 11th of May 1362 he settled at Padua, from the neighbourhood of which he never moved again to any great distance. The same year saw him at Venice, making a donation of his library to the republic of St Mark. Here his friend Boccaccio introduced to him the Greek teacher Leontius Pilatus. Petrarch, who possessed a MS. of Homer and a portion of Plato, never acquired the Greek language, although he attempted to gain some little knowledge of it in his later years. Homer, he said, was dumb to him, while he was deaf to Homer; and he could only approach the Iliad in Boccaccio's rude Latin version. About this period he saw his daughter Francesca happily married and undertook the education of a young scholar from Ravenna, whose sudden disappearance from his household caused him the deepest grief. This youth has been identified, but on insufficient grounds, with that Giovanni Malpaghini of Ravenna who was destined to form a most important link between Petrarch and the humanists of the next age of culture. Gradually his oldest friends dropped off. Azio di Correggio died in 1362, and Laelius, Simonides, Barbato, in the following year. His own death was reported in 1365; but he survived another decade. Much of this last stage of his life was occupied at Padua in a controversy with the Averroists, whom he regarded as dangerous antagonists both to sound religion and to sound culture. A curious treatise, which grew in part out of this dispute and out of a previous duel with physicians, was the book U pon his own Ignorance and that of many others. At last, in 1369, tired with the bustle of a town so big as Padua, he retired to Arqua, a village in Euganean hills, where he continued his usual train of literary occupations, employing several secretaries, and studying unremittingly. All through these declining years his friendship with Boccaccio was maintained and strengthened. It rested on a solid basis of mutual affection and of common studies, the different temperaments of the two scholars securing them against the disagreements of rivalry or jealousy. One of Petrarch's last compositions was a Latin version of Boccaccio's story of Griselda. On the 18th of July 1374 his people found the old poet and scholar dead among his books in the library of that little house which looks across the hills and lowlands towards the Adriatic.

When we attempt to estimate Petrarch's position in the history of modern culture, the first thing which strikes us is that he was even less eminent as an Italian poet than as the founder of Humanism, the inaugurator of the Renaissance in Italy. What he achieved for the modern world was not merely to bequeath to his Italian imitators masterpieces of lyrical art unrivalled for perfection of workmanship, but also, and far more, to open up the fields of Latin poetry beyond his day. Standing at the threshold of the middle ages, he surveyed the kingdom of the modern spirit, and, by his own inexhaustible industry in the field of scholarship and study, he determined what we call the revival of learning. By bringing the men of his own generation into sympathetic contact with antiquity, he gave a decisive impetus to that European movement which restored freedom, self-consciousness, and the faculty of progress to the human intellect. He was the first man to collect libraries, to accumulate coins, to advocate the preservation of MSS. For him the authors of the Greek and Latin world were living men—more real, in fact, than those with whom he corresponded; and the rhetorical epistles he addressed to Cicero, Seneca and Varro prove that he dwelt with them on terms of sympathetic intimacy. So far-reaching were the interests controlled by him in this capacity of humanist that his achievement as an Italian lyricist seems by comparison insignificant.

Petrarch's ideal of humanism was essentially a noble one. He regarded the orator and the poet as teachers, bound to complete themselves by education, and to exhibit to the world an image of perfected personality in prose and verse of studied beauty. Self-culture and self-effectuation seemed to him the highest aims of man. Everything which contributed to the formation of a free, impassioned, liberal individuality he regarded as praiseworthy. Everything which retarded the attainment of that end was contemptible in his eyes. The authors of antiquity, the Holy Scriptures and the fathers of the Church were valued by him as one common source of intellectual enlightenment. Eminently religious, and orthodox in his convictions, he did not seek to substitute a pagan for the Christian ideal. This was left for the scholars of the 15th and 16th centuries in Italy. At the same time, the Latin orators, historians and poets were venerated by him as depositaries of a tradition only second in importance to revelation. For him there was no schism between Rome and Galilee, between classical genius and sacred inspiration. Though the latter took the first rank in relation to man's eternal welfare, the former was necessary for the perfection of his intellect and the civilization of his manners. With this double ideal in view, Petrarch poured scorn upon the French physicians and the Italian Averroists for their illiberal philo-Semitism, no less than for their materialistic impiety. True to his conception of independent intellectual activity, he abstained from a legal career, refused important ecclesiastical office, and contented himself with paltry benefices which implied no spiritual or administrative duties, because he was resolved to follow the one purpose of his life—self-culture. Whatever in literature revealed the hearts of men was infinitely precious to him; and for this reason he professed almost a cult for St Augustine. It was to Augustine, as to a friend or a confessor, that he poured forth the secrets of his own soul in the book De contemptu mundi.

In this effort to realize his truest self Petrarch was eminently successful. Much as he effected by restoring to the world a sound conception of learning, and by rousing that genuine love and curiosity which led to the revival, he did even more by impressing on the age his own full-formed and striking personality. In all things he was original. Whether we regard him as a priest who published poem after poem in praise of an adored mistress, as a plebeian man of letters who conversed on equal terms with kings and princes, as a solitary dedicated to the love of nature, as an amateur diplomatist treating affairs of state with pompous eloquence in missives sent to popes and emperors, or as a true man of letters for change of scene, ready to climb mountains for the enjoyment of broad prospects over spreading landscapes; in all these divers manifestations of his peculiar genius we trace some contrast with the manners of the 14th century, some emphatic anticipation of the 16th. The defects of Petrarch's character were no less striking than its qualities, and were indeed their complement and counterpart. That vivid conception of intellectual and moral self-culture which determined his ideal took the form in actual life of all-absorbing egotism. He was not content with knowing himself to be the leader of his age. He claimed autocracy, suffered no interference, and, with his washed hair and a black beard, demanded unconditional submission to his will and judgment. Petrarch was made up of contradictions. Praising solitude, playing the hermit at Vaucluse, he only loved seclusion as a contrast to the society of courts. While he penned dissertations on the futility of fame and the burden of celebrity he was trimming his sails to catch the breeze of popular applause. No one professed a more austere morality, and few medieval writers indulged in cruder satire on the female sex; yet he passed some years in the society of a concubine, and his living masterpiece of art is the apotheosis of chivalrous passion for a woman. These discords of an undecided nature displayed themselves in his political theories and in his philosophy of conduct. In one mood he was fan of the antique patriot; in another he affected the monastic saint. He was clamorous for the freedom of the Roman people; yet at one time he called upon the popes to re-establish themselves in the Eternal City; at another he besought the emperor to make it his headquarters; at a third he hailed in Rienzi the founder of a new republic. He did not perceive that all these plans were
incompatible. His relations to the Lombard nobles were equally at variance with his professed patriotism; and, while still a housemate of Visconti and Correggi; he kept on issuing invectives against the tyrants who divided Italy. It would not be difficult to multiply these antitheses in the character and the opinions of this singular man. But it is more to the purpose to remark that they were harmonized in a personality of potent and enduring force.

The point to notice in this complex personality is that Petrarch's ideal remained always literary. As philosopher, politician, historian, essayist, orator, he aimed at lucid and harmonious expression—not, indeed, neglecting the importance of the material he undertook to treat, but approaching his task in the spirit of an artist rather than a thinker or a man of action. This accounts for his bewildering versatility, and for his apparent want of grasp on conditions of fact. Viewed in this light Petrarch anticipated the Italian Renaissance in its weakness—that philosophical superficiality, that tendency to ornate rhetoric, that preoccupation with stylistic trifles, that want of profound conviction and stern sincerity, which stamp its minor literary products with the note of mediocrity. Had Petrarch been possessed with a passion for some commanding principle in politics, in art, in life, he would have been an artist, in the true sense, and he might have composed his sonnets to Laura, or the controlling passion of his life might have been that for personal glory and the ideal of artistic culture, it is not wholly impossible that Italian humanism might have assumed a manlier and more conscientious tone. But this is not a question which admits of discussion; for the conditions which made Petrarch what he was were already potent in Italian society. He did but express the spirit of the period he opened; and it may also be added that his own ideal was higher and severer than that of the illustrious humanists who followed him.

As an author Petrarch must be considered from two points of view—first as a writer of Latin verse and prose, secondly as an Italian lyricist. In the former capacity he was speedily outstripped by more fortunate scholars. His elegoes and epistles and the epic of Africa, on which he set such store, exhibit a comparatively limited command of Latin metre. His treatises, orations, and familiar letters, though remarkable for a prose style which is eminently characteristic of the man, are not distinguished by purity of diction. Much as he admired Cicero, it is clear that he had not freed himself from current medieval Latinity. Seneca, and Marcus Aurelius, at any rate, had been to Petrarch more than names in composition. At the same time it will be conceded that he possessed a copious vocabulary, a fine ear for cadence, and the faculty of expressing every shade of thought or feeling. What he lacked was that insight into the best classical masterpieces, that command of the best classical diction, which is the product of successive generations of scholarship. To attain to this, Giovanni da Ravenna, Colluccio Salutato, Poggio and Filelfo had to labour, before a Poliziano and a Bembo finally prepared the path for an Erasmus. Had Petrarch been born at the close of the 15th instead of at the opening of the 14th century there is no doubt that his Latinity would have been as pure, as versatile, and as pointed as that of the witty stylist of Rotterdam.

With regard to his Italian poetry Petrarch occupies a very different position. The Rime in Vita e Morte di Madonna Laura cannot become obsolete, for perfect metrical form has here been married to language of the choicest and the purest. It is true that even in the Canzoniere, as Italians prefer to call their collection of lyrics, Petrarch is not devoid of faults belonging to his age, and affectations which have imposed themselves with disastrous effect through his authority upon the literature of Europe. He appealed in his odes and sonnets to a restricted audience already educated by the chivalrous love-poetry of Provence and by Italian imitations of that style. He was not careful to exclude the commonplaces of the school, nor anxious to finish a work of art wholly free from fashionable graces and from contemporary conceits. There is therefore a certain element of artificiality in his treatment; and this, since it is easier to copy defects than excellences, has been perpetuated with wearisome monotony by versifiers who chose him for their model. But, after making due allowance for peculiarities, the abuse of which has brought the name of Petrarchist into contempt, we can agree with Shelley that the lyrics of the Canzoniere "are as spells which unseal the inmost enchanted fountains of the delight which is the grief of love." Much might be written about the peculiar position held by Petrarch between the metaphysical lyricists of Tuscany and the more realistic amorists of succeeding generations. True in this respect also to his anticipation of the coming age, he was the first Italian poet of love to free himself from allegory and mysticism. Yet he was far from approaching the analysis of emotion with the directness of a Heine or De Musset. Though we believe in the reality of Laura, we derive no clear conception either of her person or her character. She is not so much a woman as woman in the abstract; and perhaps on this very account the poems written for her by her lover have been taken to the heart by countless lovers who came after him. The method of his art is so generalizing, while his feeling is so natural, that every man can see himself reflected in the singer and his mistress shadowed forth in Laura. The same criticism might be passed on Petrarch's descriptions of nature. That he felt the beauties of nature keenly is certain, and he frequently touches them with obvious appreciation. Yet he has written nothing so characteristic as an inscription of a flower. Petrarch's barn is an abstract; there are no flowers and water. The Canzoniere is therefore one long melodious monody poured from the poet's soul, with the indefinite form of a beautiful woman seated in a lovely landscape, a perpetual object of delightful contemplation. This disengagement from local circumstance without the sacrifice of emotional sincerity is a merit in Petrarch, but it became a fault in his imitators. Lacking his intensity of passion and his admirable faculty for seizing the most evanescent shades of difference in feeling, they degenerated into colourless and lifeless insipidities made insupportable by the rigid repetition of tropes and conceits which we are fain to pardon in the master.

Petrarch did not distinguish himself by love-poetry alone in the Italian language. His odes to Giacomo Colonna, to Cola di Rienzi and to the princes of Italy display him in another light. They exhibit the oratorical fervour, the pleader's eloquence in its most perfect lustre, which Petrarch possessed in no less measure than subjective passion. Modern literature has nothing nobler, nothing more harmonious in the declamatory style than these three patriotic effusions. That spirit of independence, so well known to us under the name of Romanticism, did not exist in Petrarch's time. Up to this point Italy had scarcely begun to exist. There were Florentines and Lombards, Guelfs and Ghibellines; but even Dante had scarcely conceived of Italy as a nation, independent of the empire, inclusive of her several component commonwealths. To the high conception of Italian nationality, to the belief in that spiritual unity which underlay her many discords and divisions, Petrarch attained partly through his disengagement from civic and local partisanship, partly through his large and liberal ideal of culture.

The materials for a life of Petrarch are afforded in abundance by his letters, collected and prepared for publication under his own eyes. These are divided into Familiar Correspondence, Correspondence with Old and New Divers Letters and Letters without a Title; to which may be added the curious autobiographical fragment entitled Epistle to Posterity. Next in importance rank the epistles and eclogues in Latin verse, the Italian poems and the rhetorical adages, especially of a religious character. Among these may be numbered the treatise De contemptu mundi, addressed to St. Augustine and styled his Secret, is invaluable. Without attempting a complete list of Petrarch's works, it may be well to illustrate the extent of his reputation and his activity as a writer by a brief enumeration of the most important. In the section belonging to moral philosophy, we find De remediis utrisque fortunae, a treatise on human happiness and unhappiness; De vita solitaria, a panegyric of solitude; De oio religiosorum, a similar essay on monastic life, inspired by a visit to his brother Gerardo in his convent near Marseilles. On historical subjects the most considerable are Rerum memorandarum libri, a collection of miscellaneous historical studies; and De viris illustribus, an epitome of the biographies of Roman worthies. Three polemical works require mention: Contra cujusdam anonymi Galli calumnias apologia, Contra medicum quemdam invectivam libri, and De sui ipsius et muliorum ignorantia—controversial and sarcastic compositions, which grew out of Petrarch's quarrels with the physicians of Avignon and the Averoists of Padua. In this connexion it might also be well to mention the remarkable
PETRE, SIR E.—PETREL

satires on the papal court, included in the Epistolas sine titulo. Five public orations have been preserved, the most weighty of which, in explanation of Petrarch’s conception of literature, is the speech delivered on the Capitol upon the occasion of his coronation. Among his Latin works are the Seepia, Africanus, taken as the first place. Twelve Eclogues and three books of Epistles in verse close the list. In Italian we possess the Cantorene, which includes odes and sonnets written for Laura during her lifetime, those of her death, and miscellaneous poems. Of these the first two contain the three patriotic odes and three famous poetical invervctives against the papal court. Besides these lyrical compositions are the semi-epic or allegorical Triomfi—Triumphs of Love, Chastity, Death—Pame, Time and Divinity. Written in a rima of smooth and limpid quality. Though these Triumphs, as a whole, are deficient in poetic inspiration, the second canto of the Triomfo della morte, in which Petrarch describes a vision of his death, are of the most famous for reserved passion and pathos tempered to a tranquil harmony.

The complete bibliography of Petrarch forms a considerable volume. Such a work was attempted by Domenico Rossetti (Trieste, 1828). It will be enough here to mention the Basel edition of 1581, in folio, as the basis for all subsequent editions of his collected works. Among editions of the Cantorene special mention may be made of those of Marsand (Padua, 1820), Leopardi in Le Monnier’s collection, Mestica (1865), and Cardini (1899). Nor must Fraccasatti’s Italian version of the Letters (published in 5 vols. by Le Monnier) be neglected. De Sade’s Life of the poet (Amsterdam, 1764-1767) marks an epoch in the history of his numerous biographies; but it is marred in many important points untrustworthy, and it has been superseded by Gustav Koerting’s exhaustive volume on Petrarchas Leben und Werke (Leipzig, 1878). Georg Voigt’s Wiederbelebungs des klassischen Alterthums (Berlin, 1899) contains a valuable addition to the researches of his great predecessor on the revival of learning. Mzière’s Petrarque (1868) is a monograph of merit. English readers may be referred to a little book on Petrarch by Henry Reeve, and to vols. ii. and iv. of Symond’s Renaissance in Italy; and also to Maf F. Jerrold, Francesco Petruccio, poet and humanist (1900).

PETRE, SIR EDWARD (1631-1690), Jesuit confessor of King James II. of England, was born in Paris. He was the son of Sir Francis Petre, Bart., of Cranham, head of a junior branch of the family of the Barons Petre, and his wife Elizabeth Gage, daughter of Sir John Gage, both strong Roman Catholics. In 1619 he was sent for his education to the Jesuit College at St Omer, and he entered the order under the name of Spencer in 1632, but did not receive the full orders till 1672. In 1679 he succeeded his elder brother in the title and family estates. On the accession of James II. in 1685 he was chosen as confessor to the king, who looked upon him as “a resolute and undertaking man.” During the whole of the king’s reign Petre was one of his advisers who did the most to encourage him in the policy which ended by producing the revolution of 1688. The king making him archbishop of York, as the see was then vacant, but the pope, Innocent XI., who was not friendly to the order, would not grant a dispensation to hold it, and even directed Petre’s superiors to rebuke him for his excessive ambition. In 1687 he was made privy councillor. When the revolution broke out Petre was employed, over-riding his disgust at the woman. After his flight he had no further relations with James II. After a visit to Rome, he became head of the Jesuit College at St Omer in 1693, from whence he was transferred to Walen in Flanders in 1697. He died on the 15th of May 1699. A younger brother Charles (1644-1712) was also a member of the order.

PETRE, SIR WILLIAM (c. 1505-1572), English politician, was a son of John Petre, a Devon man, and was educated at Exeter College, Oxford, afterwards becoming a fellow of All Souls’ College. He entered the public service in early life, owing his introduction therein doubtless to the fact that at Oxford he had been tutor to Anne Boleyn’s brother, George Boleyn, Viscount Rochford, and began his official career by serving the English government abroad. In 1536 he was made deputy, or proctor, for the vice-general, Thomas Cromwell, and as such he presided over the commission which met in June to look into the state of the monasteries. In 1543 Petre was knighted and appointed secretary of state; in 1545 he was sent as ambassador to the emperor Charles V. A very politic man, he retained his position under Edward VI. and also under Mary, forsaking the protector Somerset at the right moment and winning Mary’s goodwill by favouring her marriage with Philip II. of Spain. He resigned his secretariaship in 1557, but took some part in public business until his death at his residence, Ingestane, Essex, on the 13th of January 1572.

His son John Petre (1549-1613) was created Baron Petre of Writtle in 1603. The 2nd baron was his son William (1575-1637), whose grandson was William, the 4th baron (c. 1626-1684). Denounced by Titus Oates as a papist, the last named was arrested with several other Roman Catholic noblemen in 1678 and, remaining without trial in the Tower of London until his death. His brother John (1629-1684) was the 5th lord, and the latter’s nephew, Robert (1685-1713), was the 7th lord. It was Robert’s action in cutting a lock of hair from a lady’s head which led Pope to write his poem “The Rape of the Lock.” The Petres have been consistently attached to the Roman Catholic faith, William Joseph, the 13th baron (1847-1893), being a priest of the Roman Catholic church, and the barony is still (1913) in existence. One of the baron’s grandsons, Sir John Petre (1878-1913), translated the Epistolarium of Pedro de Ribadeneyra as Lives of the Saints (St Omer, 1699; London, 1739).

PETREL, the general name of a group of birds (of which more than 100 species are recognized), derived from the habit which some of them possess of apparently walking on the surface of the water as the apostle Peter (of whose name the word is a diminutive form) is said to have done. The petrels, all of which are placed in the family Procellariidae, were formerly associated with the Laridae (see GULL), but they are now placed as the sole members of the suborder Tubinares (the name denoting the characteristic tubular structure of their nostrils) and of the order Procellariniformes (see BIRD). They are subdivided into four groups or subfamilies: (1) Pelecandiinae (Hoticornis), containing some three or four species known as diving-petrels, with habits very different from others of the family, and almost peculiar to high southern latitudes from Cape Horn to New Zealand; (2) Procellariinae, or petrels proper (and shearwaters); (3) Diomedeinae, or albatrosses (see MALLEMUCK); and (4) Oceanitinae, containing small sooty-black birds of the genera Cynmodroma, Peloas, Pelagodroma, Garrodia and Oceanites, the distinctive nature of which was first recognized by Coues in 1864.

Petrels are arctic oceanic forms, with great powers of flight, dispersed throughout all the seas and oceans of the world, and some species apparently never resort to land except for the purpose of nidification, though nearly all are liable at times to be driven ashore, and often very far inland, by gales of wind. It would also seem that during the breeding-season many of them are wholly nocturnal in their habits, passing the day in holes of the rock in which they nest. For instance the petrel, which generally nests, the hen of each pair laying a single white egg, sparsely speckled in a few species with fine reddish dots. Of those species that frequent the North Atlantic, the common Storm-Petrel, Procellaria pelagica, a little bird which has to the ordinary eye rather the look of a Swift or Swallow, is the “Mother Carey’s chicken” of sailors, and is widely believed to be the harbinger of bad weather; but seamen hardly discriminate between this and others nearly resembling it in appearance, such as Leach’s or the Fork-tailed Petrel, Cymbrachora leucorrhoa, a rather larger but less common bird, and Wilson’s Petrel, Oceanites oceanicus, the type of the Family Oceanitidae mentioned above, which is more common on the American side. But it is in the Southern Ocean that Petrels most abound, both as species and as individuals. The Cape-Pigeon or Pintado Petrel, Daption capensis, is one that has long been well known to mariners and other wayfarers on the great waters, while those who voyage to or from Australia, whatever be the route they take, are

1Thus Ostrelata hassi, which is the Capped Petrel, a species whose proper home seems to be Guadeloupe and some of the neighbouring Windward Islands, has occurred on the State of New York, near Boulogne, in Norfolk, and in Hungary (Ibis, 1884, p. 202).
certain to meet with many more species, some, as Ossifraga gigantica, as large as Albartrosses, and several of them called by sailors a variety of choice names, generally having reference to the strong smell of musk emitted by the birds, among which that of "Stibni not" is not the most approbrious. None of the Petrels are endowed with any brilliant colouring—sooty-black, grey of various tints (one of which is often called "blue"), and white being the only hues the plumage exhibits.

The distribution of the several species of Petrels in the Southern Ocean has been treated by A. Milne-Edwards in the Annales des sciences naturelles for 1882 (6th series Zoologie, vol. xiii. art. 4, pp. 1-22).

PETRIE, GEORGE (1790-1866), Irish antiquary, was the son of James Petrie, a native of Aberdeen, who had settled in Dublin in January 1790, and was educated as an artist. Besides attaining considerable reputation as a painter of Irish landscape, he devoted himself to the study of the antiquities of the country. In 1828 he was appointed to conduct the antiquarian and historical section of the ordnance survey of Ireland. In 1832 he became editor of the Dublin Penny Journal, a periodical devoted to disseminate information among the masses, to which he contributed numerous articles on the history of the fine arts in Ireland. Petrie may be regarded as the first scientific investigator of Irish archaeology, his contributions to which are also in themselves of much importance. His Essay on Round Towers, for which in 1830 he received the prize of the Irish Academy, still ranks as a standard work. Among his other contributions to Irish archaeology are his Essay on the Military Architecture of Ireland and his History and Antiquities of Tara Hill. He died on the 17th of January 1866.

See the Life and Labours in Art and Archaeology of George Petrie, by William Stokes (1868).

PETRIE, WILLIAM MATTHEW FLINDERS (1853- ), English Egyptologist, was born at Charlton on the 3rd of June 1853, being the son of William Petrie, C.E. His mother was the daughter of Captain Matthew Flinders, the Australian explorer. He took an early interest in archaeological research, and between 1875-1876 was busily engaged in studying ancient British remains at Stonehenge and elsewhere; in 1880 he published his book on Stonehenge, with an account of his theories on this subject. He was also much interested in ancient weights and measures, and in 1875 published a work on Inductive Metrology. In 1881 he began a long series of important surveys and excavations in Egypt, beginning with the pyramids at Giza, and following up the work there by excavations at the great temple at Tanis (1884), and discovering and exploring the long-lost Greek city of Naucratis in the Delta (1885), and the towns of Am and Daphne (1886), where he found important remains of the time when they were inhabited by the Pharaohs. Between 1888 and 1890 he was at work in the Fayum, opening up Hawara, Kahun and Lischish; and in 1891 he discovered the ancient temple at Medum. Much of this work was done in connexion with the Palestine Exploration Fund. By this time his reputation was established. He published in 1893 his Ten Years' Diggings in Egypt, was given the honorary degree of D.C.L. by Oxford, and was appointed Edwards Professor of Egyptology at University College, London. In 1894 he founded the Egyptian Research Academy, of which he was the first of the two schools of Archaeology in Egypt (not to be confused with the Egypt Exploration Fund, founded 1882). Perhaps the most important work which the School has accomplished has been the investigation of the site of Memphis (q.v.)

The extent as well as the chronological order of Professor Petrie's excavations may best be shown by a list of his works.

Works.—His chief general works on Egyptian subjects are: Ten Years' Diggings in Egypt (1893); History of Egypt (1894-1900); Papyrus Tales (1896); Religion and Cosmology in Ancient Egypt (1897); Syby and Egypt (1898); Royal Tombs of the First Dynasty (1900); Royal Tombs of the Earliest Dynasties (1901); Hyksos and Israelite Cities (1906); Religion of Ancient Egypt (1906); Personal Religion (1908). On particular sites, Petrie and Tombs of the Kings (1893); Nivineh and Baku (1888); Tell el Amarna (1893); Koptos (1896); Nogada (1896); Six Temples at Thebes (1897); Deshasheh (1897); Denderah (1900); Dapollis (1901; Abydos I. (1902); Abydos II. (1903); Ekusaret (1904); Egyptians in Sinait and Researches in Sinai (1906); Gizeh and Kefeh (1907); Abydesi (1908); Memphis and Qurnah (1909).

PETRIOU also called Chia-chang-sao, a town and port of Siam, in the division of Pachim, about 45 m. E. of Bangkok. It is the centre of that part of southern Siam which is watered by the Bang Pakong River. It is built on low-lying, swampy ground, about 10 m. from the mouth of the above river. The population is about 10,000, mixed Siamese and Chinese, the latter slightly predominating. Rice-mills give employment to a large number of indented Chinese coolies, but the inhabitants are chiefly engaged in agriculture. A railway connecting with Bangkok was opened in the spring of 1908.

PETROE, a town and port of entry in Lambton county, Ontario, Canada, situated 42 m. W. of London on Bear Creek, an affluent of Sydenham River, and on the Grand Trunk and Michigan Central railways. Pop. (1901), 4735. It is in the midst of the oil region of Canada, and numerous wells in the vicinity have an aggregate output of about 30,000,000 gallons of crude oil per annum, much of which is refined in the town.

PETROLEUM (Lat. petra, rock, and oleum, oil), a term which, in its widest sense, embraces the whole of the hydrocarbons, and includes coal-tar, asphaltum, and pitch. Petroleum, however, is nearly always used to denote the genuine oil of natural origin, as opposed to coal-tar. Here the application of the term is limited to the liquid which is so important an article of commerce, though references will also be made to natural gas which accompanies petroleum. Descriptions of the solid forms will be found in the articles on asphaltum, albertite, elaterite, gilsonite, hatchettite and ozokerite. Particulars of the shales which yield oil by destructive distillation are given in the article on paraffin.

Ancient History.—Petroleum was collected for use in the most remote ages of which we have any records. Herodotus describes the oil pits near Ardericca (near Babylon), and the pitch spring of Zacynthus (Zante), whilst Strabo, Dioscorides and Pliny mention the use of the oil of Agrigentum, in Sicily, for illumination, and Plutarch refers to the petroleum found near Ebcatana (Kerkuk). The ancient records of China and Japan are said to contain many allusions to the use of natural gas for lighting and heating. Petroleum ("burning water") was known in Japan in the 7th century, whilst in Europe the gas springs of the north of Italy led to the adoption in 1226 by the municipality of Salsomaggiore of a salamander surrounded by flames. It was published in 1557 that the pools and springs of Baku towards the end of the 13th century; the medicinal properties of the oil of Tegernsee in Bavaria gave it the name of "St Quirinus's Oil." in 1436; the oil of Pechelbronn, Elssas, was discovered in 1498, and the "earbhalsam" of Galicia was known in 1506. The earliest mention of American petroleum occurs in Sir Walter Raleigh's account of the Trinidad pitch-lake in 1555; whilst thirty-seven years later, the account of a visit of a Franciscan, Joseph de la Roche d'Allion, to the oil springs of New York was published in Sagard's Histoire du Canada. In the 17th century, Thomas Shirley brought the natural gas of Wigan, in Shropshire, to the notice of the Royal Society. In 1724 Hermann Boernoe referred to the oleum terrae of Buruma, and "Barbados tar" was then well known as a medicinal agent. A Russian traveller, Peter Kalm, in his work on America, published in 1748, showed on a map the oil springs of Pennsylvania, and about the same time Raievich referred to the "liquid bitumen" of Rumania.

Modern Development and Industrial Progress.—The first commercial exploitation of importance appears to have been the distillation of the oil at Allerton in Derbyshire by James Young, who patented his process for the manufacture of paraffin in 1859. In 1855 and 1856 patents for the preparation of this substance from petroleum were obtained by Warren de la Rue, and the process was applied to the "Rangoon oil" brought to Great Britain from Yenangyaung in Upper Burma. The active growth of the petroleum industry of the United States began in 1859, though in the early part of the century the petroleum of Lake Seneca, N.Y., was used as an embrocation under the
PETROLEUM

name of "Seneca oil," and the "American Medicinal Oil" of Kentucky was largely sold after its discovery in 1858. The Pennsylvania Rock Oil Company was formed in 1854, but its operations were unsuccessful, and in 1858 certain of the members founded the Seneca Oil Company, under whose direction E. L. Drake started a well on Oil Creek, Pennsylvania. After drilling had been carried to a depth of 60 feet, on the 28th of August 1859, the tools suddenly dropped into a crevice, and on the following day the well was found to have "struck oil." This well yielded 25 barrels a day for some time, but at the end of the year the output was at the rate of 15 barrels. The production of crude petroleum in the United States was officially reported to have been 2000 barrels in 1859, 4,215,000 barrels in 1860, 19,014,146 barrels in 1879, 35,103,513 barrels in 1889, 57,084,428 barrels in 1899, and 126,493,936 barrels in 1906. From Oil Creek, development spread first over the eastern United States and then became general, subsequently embracing Canada (1862), recently discovered fields being those of Illinois, Alberta and California (44,854,737 barrels in 1908).

For about 10 years Pennsylvania was the one great oil producing state, but since 1870 the industry has spread all over the world. From the time of the completion on the Baku field of the first flowing well (which was unmanageable and resulted in the loss of the greater part of the oil), Russia has ranked second in the list of producing countries, whilst Galicia and Rumania became prominent in 1878 and 1880 respectively. Sumatra, Java and Borneo, where active development began in 1883, 1886 and 1896, bid fair to rank long before among the chief sources of the oil supplies of the world. Similarly, Burma, where the Burmah Oil Company have, since 1890, rapidly extended their operations, is rising to a position of importance. Oil fields are being continually opened up in other parts of the world, and whilst America still maintains her position as the largest petroleum producer, the world’s supplies are now being derived from a steadily increasing number of centres.

Physical and Chemical Properties.—Although our information respecting the chemical composition of petroleum has been almost entirely gained since the middle of the 18th century, a considerable amount of empirical knowledge of the substance was possessed by chemists at an earlier date, and there was much speculation as to its origin. In his Syllae syllarum (1627), Francis Bacon states that "the original concretion of bitumen is a mixture of a fiery and watery substance," and observes that flame "attracts" the naophtha of Babylon "far off." P. J. Macquer (1764), T. O. Bergman (1784) Charles Hatchett (1788) and others also expressed views with regard to the constitution and origin of bitumens. Of these early writers, Hatchett is the most explicit, the various bituminous substances being by him classified and defined. Jacob Joseph Wintell, in 1788, appears to have been the first to examine petroleum chemically, but the earliest systematic investigation was that carried out by Professor B. Silliman, Jun., in 1855, who then reported upon the results which he had obtained with the "rocks or petroleum" of Venango county, Pennsylvania.

This report has become a classic in the literature of petroleum. The distillation products of petroleum may be divided into three general classes:—gaseous, volatile, and refractory. The gaseous products are generally inflammable, and range in boiling point from about 375°F. to 60°F. These are collected in the condensing towers near the 

PETROLEUM

Even prior to the discovery of petroleum in commercial quantities, a number of chemists had made determinations of the chemical composition of several different varieties, and these investigations, supplemented by those of a later date, show that petroleum consists of about 84% by weight of carbon with 12% of hydrogen, and varying proportions of sulphur, nitrogen and oxygen. The principal elements are found in various combinations, the hydrocarbons of the Pennsylvania oils being mainly paraffins (q.v.), while those of Caucasian petroleum belong for the most part to the naphthenes, isomeric with the olefines (q.v.).

Paraffins are found in all crude oils, and olefines in varying proportions in the majority, while acetylene has been found in Baku oil; members of the benzene group and its derivatives, notably benzene and toluene, occur in all petroleum. Naphthenes are the chief components of some oils, as already indicated, and occur in varying quantities in many others. Certain crude oils have also been found to contain camphens, naphthalene and other aromatic hydrocarbons. It is found that transparent oils under the influence of light absorb oxygen, becoming deeper in colour and opalescent, while strong acidity and a penetrating odour are developed, these changes being due to the formation of various acid and phenylated compounds, which are also occasionally found in fresh oils. The residues from petroleum distillation have been shown to contain very dense solids and liquids of high specific gravity, having a large proportion of carbon and possessed of remarkable fluorescent properties.

Natural gas is found to consist mainly of the lower paraffines, with varying quantities of carbon dioxide, carbon monoxide, hydrogen, nitrogen and oxygen, in some cases also sulphurred hydrogen and possibly ammonia. This mixture dissolves in petroleum, escaping when the oil is stored, and conversely it invariably carries a certain amount of water and oil, which is deposited on compression.

Occurrence.—Bitumen is, in its various forms, one of the most widely-distributed of substances, occurring in strata of every geological age, from the lowest Archean rocks to those now in the process of deposition, and in greater or less quantity throughout both hemispheres, from Spitzbergen to New Zealand, and from California to Japan. The occurrence of commercially valuable petroleum, however, is limited, bitumen deposits being confined to rocks younger than the Cambrian and older than the Quaternary, while the majority of developed oil-fields have been discovered north of the equator.

The main reservoirs of petroleum in the oil field are a porous reservoir and an impervious cover. Thus, while the mineral may be formed in a stratum other than that in which it is found, in many cases it is indigenous to it, for the formation of a natural reservoir of the fluid (whether liquid or gas) it is necessary that there should be a stratum in which a rock is typically compounded by a coarse-grained sandstone or conglomerate, while a limestone may be naturally porous, or, like the Trenton limestone of Ohio and Indiana, rendered so by its carbonation. The porosity of the porous stratum should be protected from water and air by an overlying shale or other impervious deposit. Water, often saline or sulphurous, is also found in these porous rocks and replaces the oil as the latter is withdrawn.

The effect of temperature and pressure vary with the different factors, structural conditions play an important part in determining the accumulation of oil and gas. The main supplies have been obtained from strata unbroken and comparatively undisturbed, but the occurrence of oil and gas is, however, comparatively limited, hitherto explored deposits being confined to rocks younger than the Cambrian and older than the Quaternary, while the majority of developed oil-fields have been discovered north of the equator.

one to ten feet. These slight differences in level, however, are to have a most powerful effect in the direction already mentioned.

It is evident that accurate knowledge of the character and structure of the rock formations in a petrolierous territory is of the greatest importance in enabling the expert to select favorable sites for drilling operations; hence on well-conducted petroleum-properties it is now customary to note the character and thickness of the oil-bearing strata very carefully. Additional data in these sections may be prepared from the records obtained. In some cases the depths are stated with reference to sea-level, instead of being taken from the surface, thus greatly facilitating the utilization of the records. The common practice is to drill with vertical wells or wells inclined a double the pressure of those drilled in the Trenton limestone, 600-800 lb. not being unusual, and even 1000 lb. having been recorded. The extreme pressure under which oil is met with at the lower strata is greatest in the western part of the United States, and least in the eastern part. The lowest stratum that has yielded oil is at a depth of 16,500 feet.

Three theories have been propounded to account for this pressure:

1. That it results from the weight of the overlying strata.
2. That it is due to water-pressure, as in artesian wells ("hydrostatic" or "artesian" theory).
3. That it is caused by the compressed condition of the gradually accumulating oil.

The most important oil rock is the Trenton limestone, which is extensive throughout the United States. Its greatest development is in the eastern part of the United States, where it occurs in the fields of Ohio, Pennsylvania, New York, New Jersey, and Delaware. It is also found in the Adirondack Mountains, in New York, and in the mountains of the Hudson Valley.

In the western part of the United States, the most important oil rock is the Mississippian formation, which is found in the fields of California, Texas, and Oklahoma. The most important field is in the vicinity of Bakersfield, California, where the oil is produced from the valley of the Kern River. The oil is black and of low specific gravity, and is said to be composed of a mixture of hydrocarbons.

The most important oil rock in the eastern part of the United States is the Pennsylvania formation, which is found in the fields of Pennsylvania, New York, and Ohio. The oil is black and of low specific gravity, and is said to be composed of a mixture of hydrocarbons.

The most important oil rock in the western part of the United States is the Permian formation, which is found in the fields of Texas, New Mexico, and Oklahoma. The oil is black and of low specific gravity, and is said to be composed of a mixture of hydrocarbons.

In the eastern part of the United States, the most important oil rock is the Mississippian formation, which is found in the fields of Pennsylvania, New York, and Ohio. The oil is black and of low specific gravity, and is said to be composed of a mixture of hydrocarbons.

The most important oil rock in the western part of the United States is the Pennsylvanian formation, which is found in the fields of Texas, New Mexico, and Oklahoma. The oil is black and of low specific gravity, and is said to be composed of a mixture of hydrocarbons.
Extraction (Technically termed Production).—The earliest system adopted for the collection of petroleum appears to have consisted in skimming the oil from the surface of the water upon which it had accumulated, and Professor Lesley states that one of the first efforts in this direction was made by a Mr George and others who were in the habit of collecting oil from the sands, "by making shallow canals 100 or 200 ft. long, with an upright board and a reservoir at one end, from which they obtained as much as they needed by removing the layer of oil by hand."

It is said that at Echigo in Japan, old wells, supposed to have been dug several hundred years ago, are existent, and that a Japanese history—called Koshirizuk, states that "burning water" was obtained in Echigo about A.D. 720.

The petroleum industry in the United States may be considered to date from the year 1859, when the first well actually drilled for the production of oil was completed by E. L. Drake. Since that time the industry has made remarkable progress, the arsienal well system previously adopted for obtaining brine and water. The drilling of petroleum wells is carried on by individuals or companies, either on lands owned by them, or on lands leased from the United States. The Delaware and converting the oil into coal. In case a certain number of wells shall be sunk within a stated period, and that a portion of the oil obtained (usually from one-tenth to one-fourth) shall be appropriated as royalty to the lessee. Such leasing has, however, as the lease, or lease, as the case may be, been proved productive. The "wild-cat" wells, sunk by speculators on untested territory or on lands which had not previously proved productive, played an important part in the early mapping out of the petroleum fields. To discover oil in the United States productive territory, it has been usual to drill along the borders of the land as far as practicable, in order to first obtain the oil which might otherwise be raised by others; and on account of the small area often considered a field, it is unusual for the number of wells to be far in excess of the number which might reasonably be sunk. Experience has proved that in one of the oil fields of the United States one well to five acres is as close as they should be drilled.

After the selection of the site, the first operation consists in the erection of the rig. The chief portion of this rig is the derrick, which consists of four strong uprights or legs held in position by guy-ropes, and usually consisting of wooden sills, which are preferred, as a foundation, to masonry. For drilling the deeper wells, the derrick, on account of the length of the "string" of drilling tools, is usually at least 70 ft. high. The top is a base, and the derrick is allowed to rest on it. The whole derrick is set up by means of timbers or a wooden sill being used, and thus the complete rig may be readily taken down and set up on a new site. The samson-post, which supports the walking beam, and the jack-stands, are dovetailed and keyed to the sill. The samson-post is placed flush with one side of the main sill, the hand-wheel jack-post being flush with the other side, so that the walking-beam, which imparts motion to the string of tools, rests upon the jack-stands.

The boiler generally used is of the locomotive type and is usually stationary, though sometimes a portable form is preferred. It is either set in the first instance at some distance from the engine and latterly driven to the engine, or driven by a separate motor. When the drill enters the oil-bearing formation, and until the oil and gas are under control, in order to minimize the risk of fire. A large boiler frequently supplies the engines of several wells. The engine, with its connecting pipe, the head-post, and the circular head, is attached to the central post, which is supported on the sills. The hand-wheel is turned by a main siller, which is attached to the post, and the hand-wheel communicates motion to the walking-beam.

The thrum-beam opens or closed by turning a grooved vertical wheel by means of an endless cord, called the telegraph, round another pulley fixed on the "head-case-post," and is thus under the control of the drill in the derrick. The head-case-post is a vertical wooden beam placed on the main sill directly below the string of tools, to receive the up- and down-stroke of the well. The position of the reversing valve is altered by means of a cord, passing over two pulleys, fixed respectively in the engine-house and on the derrick. At one end of the hand-wheel is the bull-rope pulley, and upon the other end of the cord, passing over two pulleys, the length of stroke of the walking-beam being thus adjusted.

The operation of the hand-wheel is checked by the use of a powerful hand-brake. The hand-wheel communicates motion to the walking-beam, while drilling is in progress, through the crank and a connecting-rod known as the pinion; to the bull-wheels, while the tools are being raised, by the bull-rope; and to the sand-pump reel, by a freely turnable shaft, having six holes to receive a moveable pinion, which is necessary that the machinery should be so arranged that the connections may be readily made and broken. The sand-pump reel is in motion by pressing a lever, the reel then being brought into contact with the face of the sand-wheel, which descends by gravitation, and its fall is checked by pressing back the lever, so as to throw the reel against a post which serves as a brake.

The sand-pump reel is set in motion by pressing a lever, the reel then being brought into contact with the face of the sand-wheel, which descends by gravitation, and its fall is checked by pressing back the lever, so as to throw the reel against a post which serves as a brake.

The oil is removed by means of a pump, called the bull-wheel, or bull-wheel, which is worked by means of a rope called the sand-wheel, to which a man is lowered into the well from the top of the derrick. The sand-wheel is worked by means of a rope called the sand-wheel, to which a man is lowered into the well from the top of the derrick.

admit of sand-pumping. The drill is thus allowed to fall freely, instead of being partly upheld by the buoyancy of the water, as in earlier wells.

Wells in Pennsylvania now range in size from 6 to 700 ft. Four or five rods in diameter are employed, having the following diameters: 10 in., 8 in., 6 in., and 5 in., the lengths of tube forming the casing being screwed together. Contractors will often undertake to drill wells of moderate depth at 90 cents to $1 per foot, but these may be as deep as 300 ft. or more.

The rotary system of drilling which is in general use in the oil-fields of the central plains of Texas is a modification of that invented by Fauvelle in 1845, and used in the early years of the industry by the some of the early oil-operators in Europe. It is one of the most rapid and economical which can be employed in soft formations, but where hard rock is encountered it is almost useless. The principle of this system consists in the use of a water-injected rotary casing, to which is attached the drilling-bit and through which a continuous stream of water, under a pressure of 40 to 100 lb. per sq. in., is forced.

The yield of petroleum wells varies within very wide limits, and the relative importance of the different producing districts is also constantly changing. I. C. White, state geologist of West Virginia, estimates that in fairly good producing sand a cubic foot of rock contains from 6 to 12 pints of oil. He assumes that in what is considered a good producing district the amount of petroleum which can be obtained from a cubic foot of rock would not be more than a gallon, and that the average weight of the oil would be from 0.25 to 0.30 of a pound. Taking these figures as a basis, the total yield of oil from an acre of petrolierous territory would be a little over 5000 barrels of 42 U.S. gallons.

Oil may often be induced in a well which would otherwise require to be pumped, by preventing the escape of gas which issues with the oil, and causing its pressure to raise the oil. The device employed for this purpose is known as the water-packer, and consists in the use of a cylinder, attached to the tubing, which is filled and forced into the well through the casing above the tubing and the well-casing, so that upon compression it makes a tight joint. The gas thus confined in the oil-chamber forces the oil up the tubing.

For use in the case of a worked-for without a cut-off, it is usual to accelerate the wells and to increase the flow.

Torpedoing Wells.

The explosive employed is generally nitroglycerin, and is kept under cool, and in a condition of constant readiness. It is laid in either the original 4 to 6 quarters to 60, 80, 100 and even 200 quarts. It is placed in tin canisters of about 3 or 5 in. in diameter and about 10 ft. in length. The canisters have conical bottoms and removable caps. They are filled with nitroglycerin, and are lowered to the bottom of the well, one after the other, by a cord wound upon a reel, until the required number have been inserted. Formerly the upper end of the highest canister was provided with a trigger which, when pulled, set off the explosive; but this feature has been omitted, in order to prevent accidental explosion.

On the completion of drilling, of great importance, it is a rule to accelerate the wells and to increase the flow.

The general practice in Great Britain is that the oil wells are operated by contractors or by oil companies, but in the United States and Canada it is generally the practice to own the oil-wells and to operate them by private people. The oil is usually conveyed from the well to the refinery by means of a pipe, which is laid along the sides of the well with or without brick. The initial diameter of the well drilled from the bottom of this pit is in some instances as much as 24 in., bore-holes of the larger size being preferred, as they are less liable to be plugged up and choked, and admit of the use of larger bailers for raising the oil.

The drilling of wells of large size requires the use of heavy tools and of very strong appliances generally. The system usually involves the use of a modification of the casing system already described, the boring rods being, however, of iron instead of wood, but the case system has also to some extent been used. For the ordinary 2-in. plain-laid manila cable a wire rope has in some cases been substituted.

Riveted iron casing, made of 3-in. plate, is employed, and is constantly lowered so as to follow the drill closely, in order to prevent caving. Within recent years, owing to the initiative of Colonel English, a method of raising oil by the agency of compressed air has been introduced to the Baku oil-fields.

In Galicia the Canadian system is nearly exclusively adopted. In some instances under-reaming is found necessary. This consists in the use of an expanding reamer by means of which the well may be drilled to a diameter admitting of the casing descending freely, which obviously could not be accomplished with an ordinary bit introduced through the casing. This reamer uses the under-reamer has been largely superseded by the eccentric bit.

The Davis calyx drill has also been employed for petroleum drilling. This apparatus may be described as a steel-pointed core-drill. The bit or bit is a metallic shell, the lower end of which is made, by a process of cutting, into a series of sharp teeth, which are set in and cut alternately. The outward set of teeth drill the hole and the inner set the core. This latter is removed by the teeth inwardly bored down the core to such a diameter as will admit of the body of the cutter passing over it without seizing. The calyx is a long tube, or a series of connected tubes, situated around the core and bearing a jet of water down the core.

In conclusion it may be stated that the two systems of drilling for petroleum which by far the largest amount of work has been, and is being done, are the American or rope method and the English or core-well method. The third is the manila casing system, which is not only employed in the United States, but is in use in Upper Burma, Java, Rumania and elsewhere. The latter was introduced by Canadians into Galicia and, with certain modifications, is now employed in the large Russian oil-fields.

A form of the rode system is used in the Russian oil-fields, but owing to the large diameter of the wells the appliances differ from those employed elsewhere.

In conclusion it may be stated that the two systems of drilling for petroleum which by far the largest amount of work has been, and is being done, are the American or rope method and the English or core-well method. The third is the manila casing system, which is not only employed in the United States, but is in use in Upper Burma, Java, Rumania and elsewhere. Crude petroleum was experimentally distilled in the United States in 1833 by Prof. Stillman (d. 1864), and the refining of petroleum in that country may be said to date from about the year 1855, when Samuel M. Kier fitted up a small refinery with a five-barrel still. The crude petroleum was obtained from salt-wells. At this period the supply of the raw material was insufficient to admit of any important development in the industry, and before the drilling of artesian wells for petroleum was initiated on the Upper Mississippi in 1870, the purpose was to secure considerable proportions in the United States. Two large refineries, one on Newtown Creek, Long Island, and another in South Brooklyn, also on Long Island, were in successful operation when the abundant new supplies of petroleum, which immediately followed the completion of the Drake well, placed at the disposal of the refiner a material which could be worked more profitably than bituminous shale.

The existing refineries were accordingly altered so as to adapt themselves to this new demand. A great quantity of burning oil from petroleum the small stills which had been in use in the distillation of shale-oil were at first employed. In the earlier refineries the stills, the capacity of which varied from 25 to 80 barrels, usually consisted of a vertical cylinder, constructed of cast- or wrought-iron, with a boiler-plate bottom and a cast-iron dome, on which the "goose-neck" was bolted. The charge was distilled almost to dryness, though the operation was not carried far enough to cause the residue to "crack." The operation was, however, completely revolutionized in the United States by the introduction of the "cracking process," and by the division of the distillation into two parts, one consisting in the distillation of the spirit, the other in the "cracking process" in the distillation (which is usually conducted in separate stills) of the residues from the first distillation, for the production of lubricating oils and paraffin.

The "cracking" process, whereby a considerable quantity of the oil which is intermediate between kerosene and lubricating oil is converted into hydrocarbons of lower specific gravity and boiling-point suitable for illuminating purposes, is one of great scientific and technical interest. It is generally understood that the products of fractional distillation, even in the laboratory, are not identical with the hydrocarbons present in the crude oil, but are in great part produced by the action of heat upon them, as is plainly stated by Professor Stillman in the earliest stages of development of the American petroleum industry. An important paper bearing on the subject was published in 1871, by T. E. Thorpe and L. H. R. Ford, in the "Chemical News," in which the action of heat under pressure on solid paraffin is discussed. They found that the paraffin was thus converted, with the evolution of but little gas, into hydrocarbons which were liquid at ordinary temperatures. By long exposure of paraffin to elevated temperatures (melting point 44.5° C.) they obtained nearly 4 litres of liquid hydrocarbons, which they subjected to fractional distillation, and on examining the fraction distilling below 100° C. they found it to contain ethyl alcohol, which, on careful distillation, might be resolved into C_2H_5 + C_2H_5 or C_2H_4 + C_2H_6, &c., the general equation of the decomposition being:

\[ C_{n+2} \text{paraffin} = C_n \text{paraffin} + C_2H_4 \text{olefine} \]

The product actually obtained is a mixture of several paraffins and several olefines.

In petroleum-producing countries, however, and particularly in the United States, the process practically consists in distilling the oils at a temperature higher than the normal boiling point of the constituents which it is desired to decompose. This may be brought about by a distillation under pressure, or by allowing the condensed distillate to fall into the highly heated residue in the still. The result of this treatment is that the comparatively heavy oils

...
PETROLEUM

undergo dissociation, as shown by the experiments of Thorpe and Young, into specifically lighter hydrocarbons of lower boiling points, and the yield of kerosene from ordinary crude petroleum may thus be greatly increased. A large number of arrangements for carrying out this process have been patented, the earliest being that of James Young, who in 1865 patented his "improvements in the manufacture of hydrogen oils." In this patent, the distillation is described as being carried out in a vertical tube, the bottom being heated by a closed stop-cock, through which the confined vapour escapes under any desired pressure. Under such conditions, distillation takes place at higher temperatures than the normal boiling-points of the materials in the still, thus facilitating the production of the best results.

The process patented by Dewar and Redwood in 1889 consists in the use of a suitable still and condenser in free communication with each other—i.e., without any valve between them—the space in the still being not under the pressure of air, carbon dioxide or other gas, under the required pressure, and the condenser being provided with a regulated outlet for condensed liquid. An objectionable feature of the system of allowing the vapour to escape from the still to the condenser through a loaded valve, viz.: the irregularity of the distillation, is thus removed, and the benefits of regular vaporization and condensation under high pressure are obtained. In the American petroleum refineries it is found that sufficient cracking can be produced by slow distillation in stills of which the upper part is sufficiently cool to allow of the condensation of the vapours of the less volatile hydrocarbons, the condensed liquid thus falling back into the heated stills and being thus partially recracked.

In the earlier stages of the development of the manufacture of mineral lubricating oils, the residues were distilled in cast-iron stills, and the lubricating properties of the products thus obtained were uncertain. The distillation was carried out in horizontal cylindrical wrought-iron or steel stills, and to introduce steam into the oil. The steam is superheated and may thus be heated to any desired temperature without the use of pressure, which is required in the distillation with the damper. By carrying the vapours away from the condenser as fast as they are generated, the injury to the products resulting from their remaining in contact with the heated surface of the still is thus prevented.

In order to separate the distillate into various fractions, and to remove as much of it as possible free from condensed steam, it is now usual to employ condensing apparatus of special form with outlet valves for the separate removal of fractions.

The process of distillation of lubricating oils under reduced atmospheric pressure is now in very general use, especially for obtaining the heavier products. The vapours from the still pass through a condenser into a receiver, which is in communication with the exhaust.

The products obtained by the distillation of petroleum are not in a marketable condition, but require chemical treatment to remove acids and water. The process is comparatively simple, the unpleasant odour to the liquid, and in the case of lamp-oils, reduces the power of rising in the wick by capillary attraction.

At the inception of the industry kerosene came into the market as a substitute for whale-oil, and the removal of water being accomplished by treatment with soda lye and lime solution. It was, however, found that after the oil so purified had been burned in a lamp, for a short time, the wick became clogged and the oil failed to rise properly. Eichel, of Baku, is stated to have been the first to introduce, in Russia, the use of sulphuric acid, followed by that of soda lye, and his process is in universal use at the present time. The rationale of this treatment is not fully understood, but the action appears to be the separation or decomposition of the aromatic hydrocarbons, fatty and other acids, phenols, tar bodies, &c., which lower the quality of the oil, the sulphuric acid removing some, while the caustic soda removes the mineral impurities and water are left in the oil. This treatment with acid and alkali is usually effected by agitation with compressed air. Oils which contain sulphur-compounds are subjected to a special process of refining in which cupric oxide or litharge is employed as a desulphurizing agent.

Testing. A large number of physical and chemical tests are applied both to crude petroleum and to the products manufactured therefrom. These tests are of great importance in determining the composition and quality of the products and in assuring the satisfaction of the consumer.

In every country in which petroleum is used, it is customary to determine the specific gravity, and the amount of water and earthy matter in suspension; the oil is also frequently subjected to a process of fractional distillation in order to determine whether there is a sufficient quantity of the more volatile fractions present.

Petroleum spirit is tested for specific gravity, range of boiling-points, and results of fractional distillation. To illuminate oil or kerosene a series of tests is applied in order that the colour, odour, specific gravity and flash-point or fire-test may be recorded.

In the testing of mineral lubricating oils the viscosity, flash-point, "cold-test," and specific gravity are the characters of chief importance. Fuel oil is submitted to certain of the foregoing tests and in addition the calorimetric value is determined. Paraffin wax is tested for melting-point (or setting-point), and the semi-refined purgatives are examined to ascertain the percentage of oil, water and dirt present.

In civilized countries provision is made by law for the testing of the flash-point or fire-test of lamp-oil (illuminating oil or kerosene), being that temperature at which the vapour of the oil will have reached a temperature of 60° C. in a closed stop-cock, or fire-test being prescribed (see below, Legislation).

The earliest form of testing instrument employed for this purpose was that of Giuseppe Tagliabue of New York, which consists of a glass bulb placed in a copper water bath heated by a spirit lamp. The bulb is filled with the oil to be tested, a thermometer placed in it and heat applied, the temperatures being noted at which, on passing a lighted splinter of wood over the surface of the oil, a flash occurs, known as the "flash temperature." The first temperature known as the flash-point, the second as the "fire-test." Such an apparatus, in which the oil-cup is uncovered, is known as an open-test instrument. In Saybolt's Electric Tester (1879) ignition is effected by a spark from an induction-coil passing between platinum points placed at a fixed distance above the oil.

Before long, however, it was found that the open-test cups (though they are employed in the United States and elsewhere at the present time) were often very untrustworthy. Accordingly Keates proposed the substitution of a closed cup in 1871, but his suggestions were not adopted. In 1875 Sir Frederick Abel, at the request of the British Government, began to investigate the question. In August 1876 he described his apparatus. This apparatus has an oil-cup consisting of a cylindrical brass or gun-metal vessel, the cover of which is provided with three rectangular holes which may be closed and opened by means of a perforated metal plate, and there is a small opening for the admission of an oscillating colza- or rape-oil lamp to be tilted so that the flame (of specified size) is brought just below the surface of the lid. The oil-cup is supported in a bath or heating-vessel, consisting of two glass cylinders, the inner containing the oil, the outer being heated by a spirit lamp, and provided with an air-space between the water-vessel and the oil-cup. Thermometers are placed in both oil-cup and water-bath, the temperature of the latter being raised to 130° F. at the present time. The oil is introduced at 60° F. and, according to the temperature then reached by slowly drawing the slide open and closing it, the speed being regulated by the swing of a pendulum suppled with the instrument. It has been found that by this method of testing petroleum products, and accordingly corrections have to be made in obtaining strictly comparative results at different pressures. The Abel-Pensky apparatus, used in India and in Germany, differs only in being provided with a clockwork arrangement for moving the slide. Numerous other forms of open-test and close-test instruments have from time to time been devised, some of which are in use in the United States and in other countries.

For the testing of the viscosity of lubricating oils the Bovery-Redwood standard-graduated viscosimetric tubes have been used in Great Britain. By means of this instrument the time occupied in the flow of a measured quantity of the oil through a small orifice at a given temperature is measured.

Uses. Petroleum has very long been known as a source of light and heat, while the use of crude oil for the treatment of wounds and cutaneous affections, and as a lubricant, was even more general and led to the raw material being an article of commerce at a still earlier date. For pharmaceutical purposes crude petroleum is no longer generally used by civilized races, though the product vaseline is largely employed in this way, and emulsions of petroleum have been administered internally in various pectoral complaints; while the volatile product termed rhigoleum has been largely used as a local anaesthetic.

For illuminating purposes, the most extensively-used product is kerosene, but both the more and the less volatile portions of petroleum are employed in suitable lamps. Petroleum products are also largely utilized in gas manufacture for, (1) the production of "air-gas," (2) the manufacture of oil-gas, and (3) the enrichment of fuel-gas. For heating purposes, the stoves employed are practically kerosene-burners, though gasoline is used as a domestic fuel in the United States. The use of petroleum as liquid fuel is dealt with under Fuel, as is the employment of its products in motors, which has greatly
increased the demand for petroleum spirit. Petroleum has largely superseded other oils, and is still gaining ground, as a lubricant for machinery and railway rolling-stock, either alone or in admixture with fixed oils. The more viscous descriptions of mineral oils have also been found suitable for use in the Esmore process of ore-concentration by oil.

Legislation.—Since the inception of the petroleum industry, most civilized countries have prescribed by law a test of flash-point or inflammability, designed in most cases primarily to afford a delimitation, of the limits of petroleum of which may be transported without the adoption of special precautions. In the United Kingdom the limit has, for the purpose in question, been fixed by the legislature at 73°F., by the “Abel-test,” which is the equivalent of the test of one-second close-test. The subject of the testing of petroleum for legislative purposes has been investigated in Great Britain by committees of both branches of the legislature, with a view to change in the law, the standard has never been raised, since such a course would tend to reduce the available supply and thus lead to an increase in price or deterioration in quality. Moreover the chief object of the Petroleum Acts passed in the United Kingdom has hitherto been to regulate storage, and it has always been possible to obtain oils either of higher or lower flash-point, when such are preferred, irrespective of the legal standard, in addition in which they may be ascertained that a properly constructed lamp used with reasonable care the ordinary oil of commerce is a safe illuminant. The more recent legislation with regard to “light locomotives” reduces the limit to the quantity which may be stored for use on “light locomotives.”

The more important local authorities throughout the country have made regulations under the powers conferred upon them by the above Acts, the test in each case being, with the “Abel-test” above mentioned, of the “keeping, sale, conveyance and hawking” of petroleum products having a flash-point below 73°F., and the Port of London authority, together with other water-way and harbour authorities in the United Kingdom, have made similar laws relating to the navigation of vessels carrying such petroleum. In other countries the flash-point standards differ considerably, as do the storage regulations. In France, the standard is 35°C. (95°F.), which is applied to oil, and according to the “Hautel-Point,” liquid hydrocarbons are divided into two classes (below and above 35°C.), considered differently in regard to quantities storable and other regulations. In Germany, the law prescribes a close-test of 28°C., which is equivalent to 86°F., and according to the “close-test ; in both these countries the weights of petroleum which may be stored in specified buildings are determined by law. In the United States, various methods of testing and various minimum standards have been adopted. In Pennsylvania, the prescribed limit is a “fire-test” of 100°F., equivalent to about 70°F., close-test, while in the State of New York it is 100°F., close-test.

PETROLOGY, the science of rocks (Gr. πέτρος), the branch of geology which is concerned with the investigation of the composition, structure and history of the rock masses which make up the accessible portions of the earth’s crust. Rocks have been defined as “aggregates of minerals.” They are the units with which the geologist deals in investigating the structure of a district. Some varieties cover enormous areas and are among the commonest among the mineral forms of the rocks. Granite, diabase, agglomerate, clay, limestone, sandstone, and shales are the most familiar rocks, while the volcanic rocks, such as basalt and andesite, form plateaux and build up lofty mountains. Such unconsolidated materials as sand, gravel, clay, soil are justly included among rocks as being mineral masses which play an important rôle in field geology. Other rock species are of rare occurrence and may be known in only one or two localities in distant parts of the earth’s surface. Nearly all rocks consist of minerals, whether in a crystalline or non-crystalline state, but the insoluble and imperishable parts of the skeletons of animals and plants may constitute a considerable portion of rocks, as for example, coral limestone, lignite beds and chalk.

Treatment of the Subject.—In this paragraph the subject matter of the science of petrology is briefly surveyed; the object is to point out the headings under which particular subjects are treated (these are indicated in a separate article on the terms printed in italics). General questions as to the nature, origin, and classification of rocks and the methods of examination are discussed in the present article; mineralogy compiles similar matter respecting the component minerals; metamorphism, micaschist, petrology and the formation of concretions are agencies which effect rocks and modify them. Three classes of rocks are recognized: the igneous, sedimentary and metamorphic. The plutonic, or deep-seated rocks, which cooled far below the surface, and are exposed as batholiths, bosses, bosses, laccolites, etc.; the volcanic, which include the rhyolite, andesite, diorite, gabbro and peridotite; related to the granites are the alluvium, gneiss, pegmatite, schist rock and microgabbrotite; to the syenites, borodinite, monzonite, nepheline-syenite and foidite; to the diorites, agpaitic, natalite, alkali syenite, andesine and augite syenite. The feldspars belong to this group and contain crystals and spherulites. The volcanic rocks, found typically as lava flows, include rhyolite and obsidian (with sometimes perlite), trachyte and phonolite (and leucitophyre which contain leucite rather than related to the commonest varieties are: petrified wood or silicified wood, petrified fossil, petrified stone, petrified wood, and petrified fossil.

Composition.—Only the commonest minerals are of importance as rock formers. Their number is small, not exceeding a hundred in all, and much less than this if we do not reckon the subdivisions into which the commoner species are broken up. The vast majority of the rocks which we seek to understand every day consist of quartz, felspar, mica, chlorite, kaolin, calcite, epidote, olivine, augite, hornblende, magnetite, haematite, limonite and a few other minerals. Each of these has a recognized position in the economy of nature. A main determining factor is the chemical composition of the mass, for a certain mineral can be formed only when the necessary elements are present in the rock. Calcite is commonest in limestones, as these contain essentially of carbonate of lime; quartz in sandstones and certain igneous rocks which contain a high percentage of silica. Other factors are of equal importance in determining the natural association or paragenesis of rock-making minerals, principally the mode of origin of the rock and the stages through which it has passed in attaining its present condition. Two rock masses may have very much the same bulk composition and yet consist of entirely different assemblages of minerals. The tendency is always for those compounds to be formed which are stable under the conditions under which the rock mass originated. A granite arises by the consolidation of a molten magma (a fused rock mass; Gr. μαγμα, from μασσεως, to knead) at high temperatures and great pressures and its component minerals are such as are formed in such circumstances. Exposed to moisture, carbonic acid and other subterranean agents at the ordinary temperatures of the earth’s surface, some of these original minerals, such as quartz and white mica are permanent and remain unaffected; others, such as mica and chlorite, are replaced by new combinations. The felspar passes into kaolin, muscovite and quartz, and if any black mica (biotite) has been present it yields chlorite, epidote, rutile and other substances. These changes are accompanied by disintegration, and the rock falls into a loose, incoherent, earthy mass which may be regarded as a sand or soil. The materials thus formed may be washed away and deposited as a sandstone or girt. The structure of the original rock is not replaced by a new one; the mineralogical constitution is profoundly altered; but the bulk chemical composition may not be very different. The sedimentary rock may again undergo metamorphism. If penetrated by igneous rocks it may be recrystallized or, if subjected to enormous pressures with heat and movement, such as attend the building of folded mountain chains, it may be converted into a gneiss not very different in mineralogical composition though radically different in structure.

Structure.—The two factors above enumerated, namely the chemical and mineral composition of rocks, are scarcely of greater
importance than their structure, or the relations of the parts of which they consist to one another. Regarded from this standpoint rocks may be divided into the crystalline and the fragmental. Inorganic matter, if free to take that physical state in which it is most stable, always tends to crystallize. Crystalline rock masses have consolidated from solution or from fusion. The vast majority of igneous rocks belong to this group and the degree of perfection in which they have attained the crystalline state depends primarily on the conditions under which they solidified. Such rocks as granite, which have cooled very slowly and under great pressures, have completely crystallized, but many lavas were poured out at the surface and cooled very rapidly; in this latter group a small amount of non-crystalline or glassy matter is frequent. Other crystalline rocks such as rock-salt, gypsum and anhydrite have been deposited from solution in water, mostly owing to evaporation on exposure to the air. Still another group, which includes the marbles, mica-schists and quartzites, are recrystallized, that is to say, they were at first fragmental rocks, like limestone, clay and sandstone and have never been in a molten condition nor entirely in solution. Certain agencies however, acting on them, have effaced their primitive structures, and induced crystallization. This is a kind of metamorphism.

The fragmental structure needs little explanation; wherever rocks disintegrate fragments are produced which are suitable for the formation of new rocks of this group. The original materials may be organic (shells, corals, plants) or vitreous (volcanic glasses) or crystalline (granite, marble, &c.); the pulverizing agent may be frost, rain, running water, or the steam explosions which shatter the lava within a volcanic crater and produce the fragmental rocks known as volcanic ash, tufts and agglomerates. The materials may be loose and incoherent (sand, clay, gravel) or compacted by pressure and the deposit of cementing substances by percolating water (sandstone, shale, conglomerate). The grains of which fragmental rocks are composed may be coarse or fine, fresh or decayed, uniform or diverse in their composition; the one feature which gives unity to the class is the fact that they are all derived from pre-existing rocks or organisms. Because they are made up of broken pieces these rocks are often said to be "clastic."

Origin of Rocks.—The study of the structure of rocks evidently leads us to another method of regarding them, which is more fundamental than those enumerated above, as the structure depends on the mode of origin. Rocks are divided into three great classes, the Igneous, the Sedimentary and the Metamorphic.

The igneous (Lat. ignis, fire) rocks have all consolidated from a state of fusion. Some of them are crystalline or "massive"; others are fragmental. The massive igneous rocks include a few which are nearly completely vitreous, and still more which contain a small amount of amorphous matter, but the majority are completely crystallized. Among the best known examples are obsidian, pumice, basalt, trachyte, granite, diorite. The fragmental igneous rocks consist of volcanic ashes more or less finely compacted.

The sedimentary rocks form a second group; they have all been laid down as deposits on the earth's surface subject to the conditions of temperature, moisture and pressure which obtain there. They include fragmental and crystalline varieties. The former consist of the debris of pre-existing rocks, accumulated in seas, lakes or dry land and more or less indurated by pressure and cementing substances. Sand, gravel, sand and clay, conglomerate, sandstone and shale are well-known examples. Many of them are fossiliferous as they contain fragments of organisms. Some are very largely made up of remains of animals or plants, more or less altered by mineralization. These are sometimes placed into a special group as rocks of organic origin; limestone, peat and coal are typical of this class. The crystalline sediments are such as rock-salt and gypsum, deposits of saline lakes or isolated portions of the sea. They were formed under conditions unfavourable to life and hence rarely contain fossils. The metamorphic rocks are known to be almost entirely altered igneous or sedimentary masses. Metamorphism consists in the destruction of the original structures and the development of new minerals. The chemical composition of the rocks however suffers little change. The rock becomes as a rule more crystalline; but all stages in the process may be found and in a metamorphosed sediment, e.g. a sandstone, remains of the original sand grains and primary fragmental structure may be observed, although extensive recrystallization has taken place. The agencies which produce metamorphism are high temperatures, pressure, interstitial moisture and in many cases movement. The effects of high temperatures are seen best in the rocks surrounding great outcrops of intrusive granite, for they have been baked and crystallized by the heat of the igneous rock (thermo-metamorphism).

In folded mountain chains where the strata have been greatly compressed and their particles have been forced to move over one another a different type of metamorphism prevails (regional or dynamic metamorphism).

Methods of Investigation.—The macroscopic (Gr. μακρός, large) characters of rocks, those visible in hand-specimens without the aid of the microscope, are very varied and difficult to describe accurately and fully. The geologist in the field depends principally on them and on a few rough chemical and physical tests; and to the practical engineer, architect and quarry-master they are all-important. Although frequently insufficient in themselves to determine the true nature of a rock, they usually serve for a preliminary classification and often give all the information which is really needed. With a small bottle of acid to test for carbonate of lime, a knife to ascertain the hardness of rocks and minerals, and a pocket lens to magnify their structure, the field geologist is rarely at a loss to what group a rock belongs. The fine grained species are often indeterminable in this way, and the minute mineral components of all rocks can usually be ascertained only by microscopic examination. But it is easy to see that a sandstone or grit consists of more or less rounded, water-worn sand-grains and if it contains dull, weathered particles of felspar, shining scales of mica or small crystals of calcite these also rarely escape observation. Shales and clay rocks generally are soft, fine grained, often laminated and not infrequently contain minute organisms or fragments of plants. Limestones are easily marked with a knife-blade, effervesce readily with weak cold acid and often contain entire or broken shells or other fossils. The crystalline nature of a granite or basalt is obvious at a glance, and while the former contains white or pink felspar, clear vitreous quartz and glancing flakes of mica, the other will show yellow-green olivine, black augite and grey striated plagioclase.

But when dealing with unfamiliar types or with rocks so fine grained that their component minerals cannot be determined with the aid of a lens, the geologist is obliged to recur to more delicate and searching methods of investigation. With the aid of the blowpipe (to test the fusibility of detached crystals), the goniometer, the magnet, the magnifying glass and the specific gravity balance, the earlier travellers attained surprisingly accurate results. Examples of these may be found in the works of von Buch, Scrope, Darwin and many others. About the end of the 18th century, Dolomieu examined crushed rock powders under the microscope and Cordier in 1815 crushed, levigated and investigated the finer ground-mass of igneous rocks. His researches of subsequent authors and he was able to announce that they consisted essentially of such minerals as felspar, augite, iron ores and volcanic glass, and did not differ in nature from the coarser grained rocks.

Nicol's name is associated with the discovery of the Nicol's prism, seems to have been the first to prepare thin slices of mineral substances, and his methods were applied by Witham (1831) to the study of plant petrifications. This method, of such far-reaching importance in petrology, was not at once made use of for the systematic
PETROLOGY

investigation of rocks, and it was not till 1858 that Sorby pointed out its value. Meanwhile the optical study of sections of crystals had been advanced by Sir David Brewster and other physicists and mineralogists and it only remained to apply their methods to the minerals visible in rock sections. Very rapid progress was made and the names of Zirkel, Allport, Vogelsang, Schuster, Rosenbusch, Bertrand, Fouqué and Leyagh are among those of the most active pioneers in the new field of research. To such importance have microscopic methods attained that textbooks of petrology at the present time are very largely devoted to a description of the appearances presented by the minerals of rocks as studied in transparent micro-sections.

A good rock-section should be about one-thousandth of an inch in thickness, with the means of a splinter of the rock, about as large as a halfpenny may be taken; it should be as fresh as possible and free from obvious cracks. By gridding on a plate of planed steel or cast iron and placing the sample on the heated iron plate and transferring to a plate of glass and smoothed with the very finest emery till all minute pits and roughnesses are removed and the surface is a uniform plane. The rock-chip is then washed and placed on a copper or iron plate which is heated by a spirit or gas lamp. A microscopic glass slide is also warmed on this plate with a drop of viscous natural Canada balsam on its surface. The more volatile ingredients of the balsam are dispersed and evaporated and the balsam is drawn off; a wafer of the rock is pressed firmly into contact with the glass plate so that the film of balsam intervening may be as thin as possible and free from air-bubbles. The preparation is cooled and then the rock chip again ground down to about four times its original thickness, and which becomes transparent, with fine emery till the desired thickness is obtained. It is then cleaned, again heated with a little more balsam, and covered with a cover glass. The labour of gridding on the front surface may be saved by gridding off the reverse or the eyepiece an analysing wedge, with an iron disk armed with crushed diamond powder. A second application of the slitter after the first face is smoothed and cemented to the glass will in expert hands leave a rock-section so thin as to be already transparent. In this way the preparation of a section may require only twenty minutes.

The microscope employed is usually one which is provided with a rotating stage beneath which there is a polarizer, and to which the microscope is mounted; alternatively the stage may be fixed and the polarizing and analysing prisms may be capable of simultaneous rotation by means of toothed wheels and a connecting-rod. If ordinary light and natural polarized light is desired, both prisms may be withdrawn from the axis of the instrument; if the polarizer only is inserted the light transmitted is plane polarized; with both prisms in position the slides will then vibrate, and one or both of the images will be affected in their position in ordinary light if a suitable magnification (say 30) be employed to see that consists of grains or crystals varying in colour, size and shape. Some minerals are colourless and transparent (quartz, mica and talc). Some are brown (rutile, tourmaline, biotite), green (diopside, hornblende, chlorite), blue (glaucophane), pink (garnet), &c. The same mineral may present a variety of colours, in the same sample, and for the boundaries between zones parallel to the surfaces of the crystals. Thus tourmaline may be brown, yellow, pink, blue, green, violet, grey or colourless, but every mineral has one or more characteristic, because most common tints. The shapes of the crystals determine in general way the outlines of the sections of them presented on the slides. If the mineral has one or more good cleavages it will be indicated by systems of cracks (see Pl. III.). The refractive index of the crystal is known by the angles which are rough, with well-defined borders if they have a much stronger refracting power and faint and in the medium in which they are mounted. Some minerals decompose readily and become turbid and semi-transparent, as in the case of the olivine feldspar algae, or clear (e.g. quartz), others yield characteristic secondary products (such as green chlorite after biotite). The inclusions in the crystals are of great interest; one mineral may enclose another, or may contain crystals of other species. Lastly the structure of the rock, that is to say, the relation of its components to one another, is usually clearly indicated, whether it be fragmental or massive; the presence of glassy matter may appear from the fracture of a glassy or from the observation of a fragment of a bubble of air in the same. The following of microscopic methods of observation may be introduced, such as the measurement of the size of the elements of the rock by the help of micrometers; their relative proportions by means of a glass plate on one square; the angles between cleavages or faces seen in section by the use of the rotating graduated stage, and the estimation of the refractive index of the mineral by comparison with those of different mounting media.

Further information is obtained by inserting the polarizer and rotating the section to see if it has a section parallel, and in this way through doubly refracting crystals in the slide is, speaking generally, broken up into two rays, which vibrate at right angles to one another. In many coloured minerals such as birefringent, chlorite, rhyolite rays have different colours, and when a section containing any of these minerals is rotated the change of colour is often very striking. This property, known as "pleochroism" (Gr. ρλωκος, more; ριχος, colour) is the value of different minerals. It is often especially intense in small spots which surround minute enclosures of other minerals, such as zircon and epidote; these are known as "pleochroic halos.

If the analysis be not made, and it is observed that it is crossed to the polarizer the field of view will be dark where there are no minerals, or where the light passes through isotrope substances such as glass, liquids and cubic crystals. All other crystalline bodies, being doubly refracting, will produce a bright yellowish or bluish image. The only exception to this rule is provided by sections which are perpendicular to the optic axes of birefringent crystals; these remain dark or nearly dark during a whole rotation, and will be seen later, their investigation is of special importance. The doubly refracting mineral sections, however, will in all cases appear black in certain places as the stage is rotated. They are called extinction angles of the rock-section, and it is on this that the determination of the double refraction in rocks is usually based. The determination of the angles of extinction is a complex business.

The first stage is to be sure that the rock-section is mounted on a perfectly flat stage or glass slides, and the position of the polarizer is such that the fields of view are as nearly as possible that of the microscope. The next step is to bring the second polarizer to the position of extinction, or the stage is rotated so that the second polarizer is in the direction of the mineral. It is brought to extinction by rotating it through a small angle either to the right or to the left, or it may be necessary to turn it a complete angle to bring it to extinction. The direction of the second polarizer when it has been brought to extinction is the first angle of extinction. The next stage is to bring the first polarizer to the position of extinction, and this is accomplished in the same way as the second polarizer. The direction of the first polarizer when it has been brought to extinction is the second direction of extinction. The difference between the two directions of extinction is the angle between the optic axes of the crystal. If the angle of extinction is not equal to 90°, the crystal has double refraction.

The determination of the angle of extinction is of great importance, as it is the only way in which the angle of the optic axes can be determined. The angle of extinction is the angle between the optic axes of the crystal. The angle of extinction is usually determined by means of a polarizing microscope, and is given in the literature as the angle of extinction.

The angle of extinction is determined by the following method. The mineral section is placed on the stage of the microscope, and the polarizer is rotated until the section is brought to extinction. The direction of the polarizer when it has been brought to extinction is the first direction of extinction. The next stage is to bring the second polarizer to the position of extinction, and this is accomplished in the same way as the first polarizer. The direction of the second polarizer when it has been brought to extinction is the second direction of extinction. The difference between the two directions of extinction is the angle between the optic axes of the crystal. The angle of extinction is usually determined by means of a polarizing microscope, and is given in the literature as the angle of extinction.

The angle of extinction is determined by the following method. The mineral section is placed on the stage of the microscope, and the polarizer is rotated until the section is brought to extinction. The direction of the polarizer when it has been brought to extinction is the first direction of extinction. The next stage is to bring the second polarizer to the position of extinction, and this is accomplished in the same way as the first polarizer. The direction of the second polarizer when it has been brought to extinction is the second direction of extinction. The difference between the two directions of extinction is the angle between the optic axes of the crystal. The angle of extinction is usually determined by means of a polarizing microscope, and is given in the literature as the angle of extinction.
PETROLOGY

...the bars of which remain parallel to the wires in the field of the eye-piece. Sections perpendicular to an optic axis of a biaxial mineral under the same conditions show a dark bar which on rotation becomes curved to a hyperbolic shape. If the section is perpendicular to the crystallography plane (Crowfoot, 1925), the two hyperbolas which on rotation open out to form two hyperbolas, the apices of which are turned towards one another. The optic axes emerge at the apices of the hyperbolas and may be surrounded by coloured rings, though owing to the thinness of the mineral in these cases only when the double refraction of the mineral is strong. The distance between the axes as seen in the field of the microscope depends partly on the axial angle of the crystal and partly on the instrument objective. If it is measured by means of an eye-piece micrometer, the optic axial angle of the mineral can be found by a simple calculation. The quartz wedge, quarter mica plate or selenite plate permit the determination of the position of the optic axis in the object. At the same time, examination of the colour or shape of the figures observed in the field. These orientations are precisely similar to those employed by the mineralogist in the examination of plates cut from crystals. It is sufficient to point out that by petrological microscope in its modern development is an optical instrument of great precision, enabling the physicist to measure physical constants of crystallized substances as well as serving to produce magnified images like the ordinary microscope. A great variety of accessory apparatus has been devised to fit it for these spectacles.

The separation of the ingredients of a crushed rock powder from one to another in order to obtain pure samples for analysis is also extensively practised. It may be effected by means of a powerful electro-magnet, which is the strength of which can be regulated at the will of the analyst. A weak magnetic field will attract magnetite, haematite and other ores of iron. Silicates containing iron will follow in definite order and biotite, sericite, augite, hornblende, garnet and similar ferro-magnesian minerals may be successively abstracted; at last only the colourless, non-magnetic compounds, such as muscovite, calcite, quartz and felspar, will remain. Chemical methods also are useful. A weak acid will dissolve the calcite from a crushed limestone, leaving only dolomite, silicates of ferric and magnesium. Hydrofluoric acid will attack felspar before quartz, and if employed with great caution will dissolve these and any glassy mineral in a rock powder before dissolving augite or hypersthene. Methods of separation by gravity have a still wider application. The simplest of these is levigation (Lat. levigare, to make smooth, levita) or treatment by a current of water; it is extensively employed in the mechanical analysis of soils and in the treatment of ores, but is not so successful with rocks, as their components do not as a rule differ very greatly in specific gravity.

Fluids are used which do not attack the majority of the rock-making minerals and at the same time have a high specific gravity. Solutions of the alkali-soluble, such as mercuric iodide (sp. gr. 3·196), cadmium borotungstate (sp. gr. 3·30), benzil acid (sp. gr. 3·12), bromide (sp. gr. 2·86), or acetylene bromide (sp. gr. 3·00) are the principal media employed. They may be diluted (with water, benzene, &c.) to any desired extent and again concentrated by evaporation. If the rock be a granite of great predominance, sp. gr. 2·65, or a dolerite (sp. gr. 2·85), quartz (sp. 2·65), olivine (sp. gr. 2·64) and orthoclase (sp. gr. 2·56) the crushed minerals will all float in methylene iodide; on gradual dilution with benzene they will be precipitated, and by the above rule. The methods above cited in this consolidation of the latter Ist known as gravity. These methods are tedious in practice, especially as it is common for one rock-making mineral to enclose another. But expert handling of fresh and suitable rocks yields excellent results and much patience and trouble is often required to obtain the most minute fraction which makes up the whole of the rock. Attention is called to the fact that the crystalline rocks not unlike the whinstones themselves and containing olivine, augite and felspar, the essential minerals of these rocks, have many glassy minerals that have undergone some degree of metamorphism, and there are many obscure points about their history upon which experiment may yet throw light. Up to the present time these experiments have been almost entirely confined to the attempt to reproduce igneous rocks by fusion of mixtures of crushed minerals or chemicals in specially contrived furnaces. The earliest researches of this sort are of those of Faussat St. Fond and of de Saussure, but Sir James Hall really laid the foundations of this branch of petrology. He showed (1798) that the whinstones (diabases) of Edinburgh were fusible and if rapidly cooled yielded black vitreous masses closely resembling natural pitchstones and obsidians; if cooled more slowly they consolidated as crystalline rocks not unlike the whinstones themselves and containing olivine, augite and felspar (the essential minerals of these rocks). Many years later Daubrée, Delesse and others carried on similar experiments, but the first notable advance was made in 1878, when Fouqué and Lévy began their researches.

They succeeded in producing such rocks as porphyrite, leucite, phonolite, basalt, and rhyolite, and obtained also various structural modifications well known to petrographers, such as the optic axis and the optic plane (Grs. Biax, serpent). Incidentally they showed that while many basic rocks (basalts, &c.) could be perfectly imitated in the laboratory, the acid rocks could not, and advanced the explanation that for the crystallization of the latter it is necessary to add a gas to natural rock magmas were indispensable mineralizing agents. It has subsequently been proved that steam, or such volatile substances as carbonic acid, molybdates, chlorides, fluorides, and a species of glass, or glassy material, were added. Sir James Hall also made the first contribution to the experimental study of metamorphic rocks by converting chalk...
**PETROLOGY**

**Fig. 1.—BANDED OBSIDIAN, KIRGHIZ (x 25).**

The rock consists of alternate bands of brown and colourless glass which have been arranged in stripes by the fluxion movement of the viscous mass before solidification. The glass is rendered granular by very minute crystals.

**Fig. 2.—FLUIDAL RHYOLITE, HUNGARY (x 15).**

In the centre are crystals of felspar, rather turbid through weathering. The matrix is partly glassy, partly felsitic, and shows the effects of streaming movements with eddies behind the felspar crystals.

**Fig. 3.—OBSIDIAN, MEXICO (x 15).**

This rock has a damascened pattern owing to the irregular mingling of streams of brown and of colourless glass. It is nearly quite free from minute crystals.

**Fig. 4.—PERLITIC OBSIDIAN, TOKAI, HUNGARY (x 15).**

The clear glassy rock is traversed by a large number of cracks, some long and straight, while others are nearly circular. These are rendered more distinct by the deposit of thin films of secondary limonite in them. The cracks are due to contraction on cooling.

**Fig. 5.—PERLITIC PITCHSTONE, MEISSEN, GERMANY (x 15).**

The perlite, rounded cracks are very clearly seen, because the rock is decomposing and becoming slightly opaque along them. At the top there is a corroded crystal of felspar, showing cleavage, with large circular enclosures of brownish glass.

**Fig. 6.—OBSIDIAN, ICELAND (x 17).**

In the clear glassy base there are rounded yellow spots (spherulites) arranged in fluxion streams.

**Fig. 7.—SPHERULITIC RHYOLITE, HLINIK, HUNGARY (x 10).**

The white, angular patches are crystals of quartz and of sanidine felspar. Between them there is a yellowish glass showing circular areas with a well-defined radiate fibrous structure (spherulites).

**Fig. 8.—SPHERULITIC FELSITE, ARRAN, SCOTLAND (x 10).**

The round spherulites of this rock are large and sometimes composite; their radiate structure is obvious. This is a devitrified pitchstone, no longer glassy but finely crystalline, and at the centres of the spherulites there are spaces occupied by a secondary deposit of quartz.

**Fig. 9.—PORPHYRITIC AND FLUIDAL RHYOLITE, HUNGARY (x 12).**

The ground mass is partly glassy, partly felsitic, and shows fluxion-banding. The large quartz is a double hexagonal pyramid, but its edges and corners are rounded by corrosion and large irregular areas of glass penetrate to its centre.
A large porphyritic felspar crystal is seen lying in a pale-brown glassy base and containing many glass inclusions of irregular shape. The felspar, in one margin especially, shows corroded outlines.

This is a non-porphyritic, hornfelsiclinc rock. Among its components the crystals of dark mica are conspicuous, and with them occur also a few plates of white mica, with perfect cleavage. The slightly turbid or granular substance is felspar, a little decomposed, and the large clear spaces are crystals of quartz.

In this variety of tourmaline-granite there are many blue needles of tourmaline, grouped in stellate clusters which are embedded in a matrix of clear quartz. These pointed needles diverge from the surfaces of larger grains of tourmaline.

The dark crystals are green hornblende, and show the outlines which are characteristic of that mineral. The cloudy grey substance between them is felspar in a somewhat weathered state.

In this rock there are porphyritic crystals of felspar and of dark brown biotite (nearly black in the photograph), with a few of green augite and magnetite. The ground-mass is finely crystalline.
into marble by heating it in a closed gun-barrel, which prevented the escape of the carbide of carbon at high temperatures. Adams and Nicholson have carried this a stage farther by subjecting marble to great pressure in hydraulic presses and have shown how the foliation of marble, frequent in natural marbles, may be produced artificially.

**Rock Classification.**—The three great classes of rocks above enumerated—the igneous, the sedimentary and the metamorphic—are subdivided in many groups which to a small extent resemble the genera and species under which the naturalist classifies the members of the animal kingdom. There are, however, no hard and fast boundaries between allied rocks. By increase or diminution in the proportions of their constituent minerals they may pass by every gradation into one another; the distinctive structures also of one kind of rock may often be traced in the same rock of another. The names used to designate such definitions adopted in establishing rock nomenclature merely correspond to selected points (more or less arbitrary) in a continuously graduated series. This is frequently urged as a reason for reducing rock classification to its simplest possible terms, and using only a few generalised rock designations. But it is clear that many apparently trivial differences tend regularly to recur, and have a real significance, and so long as any variation can be shown to be of this nature it deserves recognition.

The *igneous rocks* (crystalline and fragmental) form a well-defined group, differing in origin from all others. The crystalline or massive variety of these rocks in many ways is the most attractive; they have been poured out at the surface and have consolidated after ejection, under conditions which are fairly well understood, so that they may be examined at active volcanoes in many instances. They range from those that are very coarse-grained to those that are extremely fine-grained. Many of these rocks, however, have been injected from below into cracks and fissures in the strata and have cooled there beneath masses which conceal them from view till exposed by denudation at a subsequent period. The members of the well-defined rock types in which they are found are often on the same outcrop, so that it is often possible to assign rock to one or other of them merely superficially. The lavas (or effusive rocks), having cooled rapidly in contact with the air, are mostly finely crystalline or glassy and, except the very finest grained, often have a distinct spherulitic or a radial aggregate structure. The massive lavas are still liquid at the moment of eruption. At this time they were exposed only to atmospheric pressure, and the steam and other gases, which they contained in great quantity, were free to escape: many important modifications arise from this, the most striking being the frequent presence of steam cavities (vesicular structure) often drawn out into elongated shapes subsequently filled up with minerals by infiltration (amygdaloidal structure). Granite, with its great number of phenocrysts, which were still creeping over the surface of the earth, the largest formed minerals (in the ground-mass) are commonly arranged in subparallel winding lines following the direction of movement (laminated structure) (see PETROLOGY, fig. 1) and in 2-9. The larger early minerals which had previously crystallized may show the same arrangement. Most lavas have fallen considerably below their original temperatures before they are emitted. In their behaviour they present a close analogy to hot solutions of salts in water, which, when they approach the saturation temperature, first deposit a crop of large, well-formed crystals (labile stage) and subsequently precipitate clouds of smaller and less perfect crystalline particles (metastable stage). In igneous rocks the first forms of crystals generally before the lava has emerged to the surface, that is to say, during the ascent from the subterranean depths to the crater of the volcano. It has frequently been verified by observation that the late emigrating crystals consist both of mica and felspar, of m-diol, liquid mass. The large, well-formed, early crystals are said to be porphyritic (PLIII. figs. 1, 2, 3); the smaller crystals of the surrounding matrix or ground-mass belong to the post-effusion stage. Among these late minerals nothing is perfectly common, so that they may then cool to form a non-porphyritic, finely crystalline rock, or if more rapidly chilled may in large part be non-crystalline or glassy (igneous rocks such as obsidian, tephryte, pitchstone (PI. I. figs. 1, 4, 5)). The common feature of glassy rocks is that there are puffed rounded bodies (spherulites: Gr. σφερεία, ball), consisting of fine dendritic fibres radiating from a centre (PL I. figs. 7, 8); they consist of imperfect crystals of felspar, mixed with quartz and tridymite; similar bodies are also found in pyroxenes and hornblende which cool slowly. Rarely these spherulites are hollow or consist of concentric shells with spaces between (lithophyse: Gr. λιθος, stone; φυλλον, bellow). Porphyritic structure, also common in glasses, consists in the presence of a puffed rounded cracks owing to contraction (see PERLITE).

The phenocrysts (Gr. φανερός, to show; φανερήλαυον, crystal) or porphyritic minerals are not only larger than those of the groundmass. As the matrix was still liquid when they formed they were free to take perfect crystalline shapes, not being interfered with by the pressure of adjacent crystals. They seem to have grown rapidly, as they are often filled with enclosures of glassy or finely crystalline material like that of the ground-mass (PI. II. fig. 1). Microscopic examination of the phenocrysts often reveals that they have had a complicated history. Their original crystal form is generally produced by the presence of layers of different composition, indicated by variations in colour or other optical properties; thus augite may be green at the centre and various shades of brown outside this; or may be pale green centrally and dark green at the outer edge. Many of the pseudomorphs of varieties of the felspars, which are common in the super-heated zones of the chamber, may show rounded corroded surfaces (PI. I. fig. 9), with the points blunted and irregular tongue-like projections of the matrix into the substance of the crystal. It is clear that after the matrix had solidified they were heated above its point of fusion for a period before the matrix solidified. Corroded phenocrysts of biotite and hornblende are very common in some lavas; they are surrounded by black rims of magnetite mixed with pale green augite. The former have been corroded by the fluids that were present at a certain stage of consolidation and has been replaced by a paragenesis of augite and magnetite which may be partially or completely substituted for the original crystal but still retains its characteristic outline.

Let us now consider the characteristics of a typical deep-seated rock like granite or diorite (PI. II. figs. 4, 5, 9). That these are igneous is proved by the manner in which they have been cooled through the strata, filling the cracks with running veins; that they have a high temperature is equally clear from the changes which they have induced in the rocks in contact with them. But as their temperature has not been increased discernibly, because of the masses which covered them, complete crystallization has taken place and no vitreous rapidly chilled matter is present. As they have had time to cool before crystallizing they are not fluidal. Their crystalline gaseous have not been able to escape through the thick layer of strata by which they were injected, and may often be observed occupying cavities in the minerals, or have occasioned many important modifications in the crystallization of the rock. Because their crystals are of approximately equal size these rocks are said to be porphyritic. What is the nature of the separation of large well-shaped crystals and a fine-grained ground-mass? Their minerals have formed, however, in a definite order, and each has had a period of crystallization which may be very distinct or may have continued for the same time as the consolidation of one or other of the other ingredients. The earlier have originated at a time when most of the rock was still liquid and are more or less perfect; the later are less regular in shape because they were compelled to occupy the interspaces left between the already formed crystals (PI. II. figs. 5, 9). The former are said to be idiomorphic (or automorphic), the latter are anidomorphic (alloidomorphic, xenomorphic). There are also other many characteristics which serve to distinguish the different kinds of the same group. For instance the granite is the typical felspar of granite, while its modification sandine occurs in lavas of similar composition. The same distinction holds between altered felspar and felspar. Leucite is common in lavas, very rare in phyllite and diorite. This is explained by the fact that in the latter the crystals which solidified were too small and did not have time to form the large, well-formed crystals that were produced in the more fluid and felspar formative. These differences show the influence of the physical conditions under which consolidation takes place.

There is a certain class of intrusive rocks which have risen uphills towards the surface, the substance has dropped up at the point, and have solidified in fissures as dikes and intrusive slits at no great depth. To this type the name intrusive (or hyp., Intrusive or Hypabyssal Types. Types.) is often given in distinction to the plutonic (or hyp., Plutonic or Hypabyssal Types., Plutonic or Hypabyssal Types.) which are formed at greater depths. As might be expected, they show structures intermediate between those of the effusive and the plutonic rocks. They are very commonly porphyritic, not rarely vitreous, and sometimes even vesicular. In fact many of them are indistinguishably petrologically from lavas of similar composition.

The attempt to form a special group of hypabyssal intrusive and dike rocks has met with much criticism and opposition. Such a group or name is not wanted. They are most easily characterized with the plutonic and the effusive. But there are many kinds of rock which are not found to occur normally in any other manner. As examples we may cite the lamprophyres, the aplite, the biotite gneiss, the porphyrite, and many other rocks which are very rare. As they are not formed by the same processes which formed the composite rocks, they are not included in the two other groups. The siliceous rocks, the lamprophyres, and the effusive rocks, the principle of following those together which resemble one another in mineral composition and in chemical composition. In a broad sense these two properties are interdependent.

I. *Idiomorphic*, having its own characteristic form. Gr. *Bios*, belonging to one's self, (εδρίς), morphé (form); alloidomorphic, from Gr. *dialeipn*, belonging to another (διαείπνον), a stranger (έπρον).
The common rock constituents are nearly all oxides; chlorine, sulphur and fluoride are the only important exceptions to this and their total amount in any rock is usually much less than 1%. W. F. Clarke has calculated that a little more than a thousandths or millionths of a gram is present. Of the many oxides which occur in the rocks, the following are the most abundant:

- Silica (SiO₂)
- Alumina (Al₂O₃)
- Lime (CaO)
- Magnesia (MgO)
- Potash (K₂O)
- Soda (Na₂O)
- Iron oxide (Fe₂O₃)
- Titanium oxide (TiO₂)
- Magnesium oxide (MgO)
- Aluminium oxide (Al₂O₃)
- Silica (SiO₂)

These oxides are normally present in all rocks in varying proportions, but there are many exceptions to this rule, especially in the case of the more basic rocks. The most common minerals in igneous rocks are:

- Quartz
- Felspar
- Hornblende
- Augite
- Apatite

The chemistry of these minerals is complex and varies greatly from one rock to another. The composition of the rocks is determined by the relative amounts of these minerals and the proportions in which they are present. For example, granite is characterized by its high content of quartz, felspar and mica, whereas basalt contains more iron and magnesium minerals. The term "ultrabasics" refers to rocks that are rich in iron and magnesium minerals and are typically深色 and dense. These rocks are often associated with deep-seated geological processes and are important in the study of the Earth's interior.

In summary, the chemical composition of rocks is a key factor in understanding their origin and evolution. The various rock types are characterized by their mineralogical and chemical properties, which are determined by the conditions under which they formed. This knowledge is essential for understanding the history of the Earth and its geological processes.
to be unique, turn up with identical features in widely scattered regions, almôite, for example, occurs in Norway, Scotland, Montreal, British Columbia, New York and Brazil, tinguiaie in Scotland, Norway, Brazil, Montana, Portugal, &c. This indicates that under certain conditions, the chemical properties and unique rock facies found in association are often due to local absorption of surrounding rocks by the molten magma ("assimilation"). Effects of this process may vary from slight to extreme, depending on the nature of the fresh rock and magma involved; and where solution is known to have gone on the products are usually of abnormal character and easily distinguishable from the common rock types.

According to modern views two explanations of these facts are possible. Some geologists hold that the different rock facies were produced by different stages of differentiation, though what its potency may be is uncertain. As a rock solidifies the minerals which crystallize follow one another in a more or less well-defined order, the most basic (according to the quartz-feldspar law) and last to crystallize. That in a general way the peripheral portions of a laccolite contain the finest and those early basic minerals suggests that the sequence of crystallization helps largely in determining the succession (and consequently the differentiation) of rocks in the igneous complex. Gravity also may play a part, for it is proved that in a general way the heaviest components will be concentrated towards the base. This, however, be of secondary importance as in lavas the top portions often consist of more basic and heavier varieties of rock than the lower parts. When the material is being slowly heated and in any case denser than the fused magma around them, will tend to sink by their own weight and to be segregated near the bottom of the mass. Electric currents, magnetic attraction and gravitational forces have all been called in to account for the phenomena observed. Magmas have also been compared to liquids which, when they cool, split up into portions no longer completely soluble in one another (liquation hypothesis). Each of these partial associations may be said to be separate but not completely separated, and the conditions change a range of liquids differing in composition may be supposed to arise.

All igneous rocks contain dissolved gases (steam, carbonic acid, &c). Hence as crystallization goes on the residual liquid may contain a greater or less amount of dissolved free water, carbonic acid, &c. Of these water is the principal, and was formerly believed to have percolated downwards from the earth's surface to the heated rocks below, but is now generally admitted to be an integral part of the magma. Some portion of this water is evolved in the solidified state, and the remainder may be either released in the form of steam and carbonic acid or may be retained in the rock as a gas. These gases, however, are not always found in the interior of the igneous complex.

These gases often do not enter into the composition of the rock-forming minerals, for most of these are free from water, carbonic acid, &c. Hence as crystallization goes on the residual liquid may contain a greater or less amount of dissolved free water, carbonic acid, &c. Of these water is the principal, and was formerly believed to have percolated downwards from the earth's surface to the heated rocks below, but is now generally admitted to be an integral part of the magma. Some portion of this water is evolved in the solidified state, and the remainder may be either released in the form of steam and carbonic acid or may be retained in the rock as a gas. These gases, however, are not always found in the interior of the igneous complex.

Not less interesting are those cases in which a single body of rock has in consolidation yielded a variety of petrographical types often widely divergent. This is best given by great plutonic bodies. Lenticular or elongated masses of granite and gabbro composed of large and small crystals which have grown up, as a rule, in a few years, but occasionally, the edges being highly acidic while the central parts consist of more basic rocks. Sometimes the later phases penetrate the earlier and may be solidified in the same position, but this phenomenon has not been described where successive emplacements of different character have proceeded outwards from the focus.

The "propylite" (Gr. ωραβλόν, a gateway) was given by Richtofen to a volcanic rock which is supposed to have marked a new epoch in volcanic geology (see ANDERSON)
PETROLOGY

astonishing completeness in the history of individual products. In each class of rock crystallization follows a definite course. The first minerals to separate belong to a group known as the minor accessories; this includes zircon, apatite, some forms of garnet, and others. The order of crystallization is hornblende, biotite, plagioclase, felspar (beginning with the varieties most rich in lime and ending with those which contain most soda), orthoclase, microcline and quartz (with micropegmatite). Many minerals which crystallize in a regular and definite way at an eutectic, some basic minerals precede the less basic; it is known as Rosenbusch’s law.

Types of Structure.—In some rocks there seems to be a close analogy for the minerals to envelop one another. This is true of many gabbroic and basaltic rocks (PI. III, 1, 7). The grains then lie side by side, with the faces of the latter superimposed exactly on the more perfect crystal outlines of the earlier. More commonly some closer relationship exists between them. When the smaller idiomorphic crystals of the first-formed are scattered irregularly through the larger and less perfect crystals of the last-formed, the structure is said to be poliklitic (Gr. τοικννδας, many-coloured, mottled). A variety of this, known as optik, (PI. III, fig. 5), is very characteristic of many dolerites and diabases, in which large plates of augite, enclosed in small crystals of plagioclase-felspar. Biotite and hornblende frequently enclose felspar optically: less commonly iron oxides and sphenes do so. In peri-
dotites the "luster-mottled" structure arises from pyroxene or hornblende enclosed in the same manner (PI. III, fig. 8). In these cases no crystallographic relation exists between the two minerals (enclosed and enclosing).

But often the surrounding mineral has been laid down on the surface of a way that it has very certain angles of faces or axes parallel to one another. This is known as \"parallel growth.\" It is best seen in zoned crystals of plagioclase, augite, which range in composition from anorthite to labradorite, and which vary in size from one face to another; some have a regular texture on the surfaces of the more basic. Biotite and muscovite, hornblende and augite, enstatite and diopside, epidote and orthite, very frequently are associated in this way.

The pyroxene, on the other hand, crystallized simultaneously they may be intergrown in \"graphic\" fashion. The best example is quartz and orthoclase occurring together as micropegmatite (PI. II, 6 and 8). The quartz forms angular patches in the felspar, which though separated have been derived from one crystal, and which is often found in definition. At the faces of the crystals, though this is not known in all cases. Augite also occurs in graphic intergrowth with hornblende, olivine and felspar; and hornblende, cordierite, eudite and biotite in graphic intergrowth.

Physical Chemistry of Igneous Rocks.—The great advances that have been made in recent years in our knowledge of physical chemistry have very important bearings on petrological investiga-
tions. A full account of the study of the general principles we may anticipate that by this means much light will be thrown on problems which are now very obscure and a complete revolution in our ideas of the conditions which affect crystallization may yet be the consequence. As yet little work of an exact and quantitative nature has been done on actual rocks or on mixtures resembling them in composition, but at the Carnegie Institution in Washington, an elaborate series of experiments on the relation between the temperature and pressure of mixtures of these is being carried on, with all the refinements which modern science can suggest. The work of Doelter and of Vogt may also be mentioned in this connexion. At the same time the question of the nature of the physical processes involved has received much attention, and serves both to direct and to elucidate the experimental work.

A fused mixture of two minerals may be regarded as a solution of one on the other. If such a solution be cooled down, crystalliza-
tion will begin at the lower temperatures. If the concentration of one of the molecules is increased by the addition of more of them, or if the temperature be lowered, an equilibrium will be established, and crystallization will cease. This mixture, which is known as the eutectic mixture, has the lowest melting-point of any which can be formed from these minerals. If heat be still abstracted the eutectic will consolidate as a whole; its melting point will be raised in the same proportion. Some substances will crystallize simultaneously when any given pressure the composition of the eutectic mixture in such a case is always the same.

Similarly, if there be three independent components (none of which forms mixed crystals with the others), the relative amounts and to the composition of the eutectic mixture one will begin to crystallize; then another will make its appearance in solid form, and when the excess of this has been removed, the ternary eutectic (that mixture of the three which has the lowest melting-point) will be produced and crystallization of the three components will go on simultaneously.

The eutectic is a very remarkable type of mixture. It is very similar to the formation of igneous rocks. Thus in certain felsites or porphyries which may be considered as being essentially mixtures of quartz and felspar, a certain amount of quartz has crystallized out at one temperature and a certain amount of felspar at another. At the same time the remaining of the rock, which is in a mixture of two or more fine-grained, cryptocrystalline or sometimes micrographic groundmass which consists of quartz and felspar in intimate mixture.

The close resemblance to the eutectic, and chemical studies have proved that in many cases the limits of the eutectic groundmass is complete.

But the comparison must not be pushed too far, as there are always other components than quartz and felspar (apatite, zircon, etc.). Moreover, they can be formed by adding the eutectic mixture to any liquid, and the eutectic mixture to any liquid, and this will result in the finer the less the eutectic mixture is poured out, the more the same type: the gases dissolving in the magma play a very important part. As crystallization goes on, these gases are set free and their pressure must increase to some extent. Moreover, the felspar is eutectic, which is formed in a way that there being always some felspar and potash felspar and usually also a small amount of lime in these porphyries.

In a typical basic rock the conditions are even more complex. A pyroxene felsite (which is a mixture of felspar, pyroxene, and this type of the latter consists of three distinct species, the former of an unknown number; and in each case they can form mixed crystals, to a greater or less extent in the same manner (PI. III., fig. 8). In these cases the properties of solutions of two or three independent components, do not necessarily explain the process of crystallization in any igneous rock.

Vesicles very frequently in porphyries not only quartz but felspar also is present in large well-formed early crystals. Similarly in basalt, augite and felspar may appear both as phenocrysts and as components of the ground-mass. As an explanation of this it has been suggested that the felspar, which is a kind of felspar, has taken place. We may suppose that the augite which was in excess of the proportion necessary to form the felspar-augite, eutectic mixture, first separated out. When the remaining solution reached the eutectic composition the felspar would crystallize out and the augite, which is necessary to initiate the process, would be left behind; augite went on crystallizing while felspar lagged behind. Then felspar began and as the mixture was now supersaturated with this mineral a considerable amount of it was rapidly thrown out of the liquid, and the felspar nucleus was left behind. This is one reason why the augite, already crystallized, to be dissolved and its crystals would be corroded, losing their sharp and perfect edges, as is often observed in rocks of this group. Thus, the necessary adjustments were made and the new rock was developed and thereby the two minerals would consolidate simultaneously (or nearly so) till crystallization was complete.

There is a good deal of evidence to show that supersaturation is not an important factor in crystallization of which they form glasses proves that under certain conditions the melts rocks are highly viscous. Much will depend also on the presence, accidental or otherwise, of nuclei on which the crescent substance can be deposited. The presence of these nuclei is very common. This is one reason why the augite, already crystallized, to be dissolved and its crystals would be corroded, losing their sharp and perfect edges, as is often observed in rocks of this group. Thus, the necessary adjustments were made and the new rock was developed and thereby the two minerals would consolidate simultaneously (or nearly so) till crystallization was complete.

On the other hand, there is plenty of evidence to show that supersaturation, though probably one of the causes, is not the principal cause of the appearance of more than one mineral in two large rocks. For example, some of the quartz-porphyries, for example, there are phenocrysts not only of quartz but also of micropegmatite. These prove that quartz and felspar were not crystallizing successively or alternately but simultaneously.

The vast majority of the minerals found in igneous rocks are not of primary composition, but are formed by the mutual alteration of secondary minerals in very different proportions. This enormously complicates the theoretical problems of consolidation. It has been found, for example, that in the case of three minerals—one of which is present in very small amounts—many possible combinations are possible. Furthermore, the conditions under which the minerals may not in such a case be the last substance to crystallize, and may not be present at all. This is very much in accordance with the observed facts of petrology; for usually in a rock there is one body which is the first to crystallize and contains no appreciable quantity of the others.

As yet we know little about such important questions as the composition of the eutectic mixtures of rock-minerals, their latent heat of fusion, specific heats, mutual solubilities, inversion tempera-
tures, &c. Until we are in possession of a large body of accurate information on such points as these the theoretical treatment of
the processes involved in the formation of igneous rocks cannot be successfully handled. But every day sees an increase in the amount of data available, and encourages us to believe that sooner or later some of the simpler igneous rocks at any rate will be completely explained.

Rock masses of igneous origin have no sooner consolidated than they begin to change. The gases with which the magma is charged are slowly dissipated, lava-flows often remain hot and sticky for many days, and the vapors and other components of the rock deposit new minerals in cavities and fissures. The beautiful zeolites, so well known to collectors of minerals, are largely of this origin. Even before these secondary alterations have commenced, the crystalline masses begin to alter. Frost, rain, carbonic acid, oxygen and other agents operate continuously, and do not cease till the whole mass has crumbled down and most of its ingredients have been resolved into more soluble form. The processes of alteration are generally considered unessential; rocks are classified and described as if they were ideally fresh, though this is rarely the case in nature.

Epigenetic change (secondary processes) may be arranged under a number of headings, each of which is typical of a group of rocks or rock-forming minerals, though usually more than one of these alterations will be found in progress in the same rock. Silification, the replacement of the minerals by crystalline or crypto-crystalline silica, is most common in acid rocks, such as rhyolite, but is also found in serpentine, &c. Kaolinization is the decomposition of the felspars, which are the commonest constituents of the acid rocks, into kaolin and quartz (pi. 1, q. v.); it is best shown by granites and syenites. Serpentinization is the alteration of olivine to serpentine (with magnetite); it is typical of peridotites, but occurs in most of the basic rocks. In general, the alteration of primary minerals results in the formation of such minerals as serpentine, chlorite, &c., very generally in diabases; chloritization is the alteration of augite (biotite or hornblende) to chlorite, and is seen in many diabases, diorites and gneissomorphs. Epoxidization occurs also in rocks of this group, and consists in the development of epidote from biotite, hornblende, augite or plagioclase felspar.

The sedimentary rocks, which constitute the second great group, have many points in common that distinguish them from the igneous and the metamorphic. They all have originated on the surface of the earth, and at the period of their formation were exposed only to the temperature of the air and to atmospheric pressure (or the pressures which exist at the bottoms of seas and lakes). Their minerals are in most cases not susceptible to change when exposed to moist air or sea, and many of them are hydrated (chlorite, micas, &c.), or oxidized (iron ores), or contain carbonic acid (calcite, dolomite). The extent, however, to which this is the case depends largely on the rapidity with which they have accumulated; coarse rocks quickly piled up often consist of materials only partly weathered. When crystalline, the sedimentary rocks are usually soluble at low temperatures, and the members of the sand-silt clays, hence they are often known as the stratified rocks; the upper beds are always of later formation than those which underlie them, except (as may happen when great disturbance has taken place) the whole series is inverted or overturned. Many of the stratified rocks have been formed by the agency of moving water (rivers, currents, &c.) and are grouped together as "aqueous" rocks; others have been deposited by the wind in deserts, on sandy beaches, &c. (these are "aeolian"). Others are the remains of animals or of plants, modified by the action of time, pressure and percolating water. Lastly, we find beds of crystalline nature, such as salt- and gypsum, which have been formed by the desiccation of saline waters; other crystalline stratified rocks, such as dolomite and many beded iron-stones, are replacement products due to the introduction of mineral matter in solution, which replaced the original rock mass partially or wholly.

When the rocks exposed at the earth's surface give way before the attack of the agencies of denudation, they crumble down and are removed into two parts: one of the accumulation of soil on the surface of the land, and the other part is dissolved and washed away. The undissolved remains of the rocks which they finally come to rest, form clastic sedimentary rocks (sandstone, conglomerate, shale, &c.). These sediments are partly transferred to the sea, where they help to increase the store of salts, and may again be precipitated as crystalline sedimentary rocks; but they are also made use of by plants and by animals to form their skeletal and vital tissues. From this latter portion the rocks of organic origin are built up. These may also contain certain ingredients derived from the atmosphere (nitrogen, carbon in coals, &c.).

We have thus three types of sediments of distinct origin, which may be named the clastic (or fragmental), the crystalline and the organic.

The clastic materials may accumulate in situ, and then differ chiefly in their disintegrated and weathered state from the parent rock masses on which they rest. The best example of this is the weathering of the fragments in coarse schists, such as the diorite, granite, serpentine, &c., and consolidates as conglomerates, breccias and pebbly grits. The bedding of these rocks is rudimentary and imperfect, and as each bed is traced along its outcrop it frequently changes its character to that of the bed below it or the bed above it. The same rock travels farthest, and is laid down in thin uniform sheets of wide extent. It is known as mud and clay; around the shores of our continents, at distances of a hundred miles and more from land, great sheets of mud are spread over the ocean floors. This mud contains minute particles of quartz and of felspar, but consists essentially of finely divided scaly minerals, which by their small size and flat shape tend to remain suspended in water for a very long time. Chlorite, white micas and kaolin are the best examples of this class of substances. Wind action is even more effective than water in separating and removing these fine particles. They do not travel over a large area, but many miles; they are blown into the sea, and become part of the lower strata of water; hence they are mostly angular. Fragments of intermediate magnitudes (from 1/16 of an inch to 1/2 of an inch) are classed as sands. They consist largely of quartz, but they do carry small particles of hornblende and augite; they are not so easily scattered by the wind as the sand grains, and do not split up into flakes like mica or chlorite. These quartz grains have been rolled along and are usually rounded and worn (pi. iv., fig. 1). More or less of garnet felspar, tourmaline, zircon, and other minerals are admixed with the quartz, because these are hard minerals not readily decomposed.

The mechanical sorting by the transporting agencies is usually somewhat incomplete, and mixed types of sediment result, such as conglomerates containing sandstones, and sandstones containing conglomerates. Moreover, successive layers of deposit may not always be entirely separable from each other, and alternations of varying composition may follow one another in thin laminae: e.g. laminae of arenaceous material in beds of clay and shale. Organic matter is frequently mingled with the finer-grained sediments.

These three types have been named the psphthic (or pebbly; Gr. ψῆφος, pebble); psmammitic (or sandy, Gr. ψαμμωμος, sand), and pelitic (or muddy; Gr. πέλας, mud).

Two groups of clastic sediments deserve special treatment.

The pyroclastic (Gr. πυρ, fire, and κάθές, broken) rocks of volcanic origin, consist mostly of broken pieces of lava (bombs, ash, &c.) (pi. i., fig. 2), and are generally composed of fossils. They are stratified, and may be coarse or fine, but are usually much less perfectly sorted out, according to their fineness, than ordinary aqueous or aeolian deposits. The glassy clays (boulder clays), representing the deposits of the ocean bottoms which are now on the world, are the most characteristic of these. They are characterized by the very variable size of their ingredients and the striated, blunted sub-angular form of the larger rock fragments. In them stratification is exceptional and fossils are very rare.

The crystalline sedimentary rocks have been deposited from solution in water. The commonest types, such as rock-salt, gypsum, anhydrite, carnallite, are known to have arisen by the evaporation of enclosed saline lakes exposed to a dry atmosphere. They occur usually in beds with layers of red clay and marl; some limestones have been formed by calcareous waters containing carbonate of lime dissolved in an excess of carbonic acid. The escape of that gas the mineral matter is precipitated (sinters, Sprudelstein, &c.). Heated waters on cooling may yield up part of their dissolved mineral substances; thus silicious sinters are produced around geysers and hot springs in many parts of the world. But also these contain the very finest, the finest to which the veinstones which fill the fissures by which these waters rise to the surface. They differ from those above enumerated in being more perfectly crystallized and in having no definite stratification, but such as may be seen in the quartz veins. These veins attack the country rock. Another subdivision of this class of rocks is due to recrystallization or crystalline replacement of pre-existing sediments. Thus limestones are dolomitized or converted into ironstones, flints and cherts being changed into jasper, &c., and the claystones and mudstones are often replaced by crystalline substances as calcite, quartz, &c.

Organic. The organic rocks, schists, and sometimes other sedimentary rocks, are built up by the remains of animals and plants. They are of great importance, as limestones and coals belong to this group. They are the most fossiliferous of all rocks; but clastic sediments are often rich in fossils. The crystalline sedimentary rocks are chiefly and to a great extent restricted to the outer world. They are sub-divided, according to their dominant components, into calcareous,
PETROLOGY

carbonaceous, siliceous, ferruginous, and so on. The calcareous organic rocks may consist principally of foraminifera, crinoids, brachiopods, mollusca, polyzoa, &c. Most of them, however, contain a mixture of organisms. By crystallization and metamorphism, stones consisting of mineral matter of any kind have the same effect. The calcareous rocks are essentially plant deposits; they include peat, lignite and coal. The siliceous organic rocks include radiolarian and diatom oozes; in the older formations, they are chiefly radiolarian oozes, and in the latest, nodules owe their silica to disseminated fossils of this nature which have been dissolved and redeposited by coalescent action. Some kinds of siliceous sinter may be produced by organisms inhabiting the surface of the water, and there may have arisen through the agency of minute plants. Bog iron ores also may be of organic rather than of merely chemical origin. The phosphatic rocks so extensively sought after as sources of fertilizing agents for use in agriculture are for the most part of organic origin, and have been dissolved and redeposited with the greatest frequency. Many varieties of animals which secrete a phosphatic skeleton; but most of them no longer show organic structures but have been converted into nodular or concretionary forms.

All these rocks at first are in an incoherent condition (e.g. sands, clays and gravels, beds of shells, &c.), and in this state they may remain for an indefinite period. Millions of years have elapsed since some of the early Tertiary strata gathered their first materials, and the more friable portions (e.g. London Clay) and differ little from many recent accumulations. There are few exceptions, however, to the rule that with increasing age sedimentary rocks become more and more indurated, and the hardening of the rock is due to the fact that the firm consistency generally implied in the term "rock." The pressure of newer sediments on underlying masses is apparently one cause of this change, though not in itself a very powerful one. The pressure of the water, the cementing materials of the rock, the percolating water, which takes up certain soluble materials and redeposits them in pores and cavities. This operation is probably accelerated by the increased pressure produced by superincumbent masses of sedimentary rocks and also by the crustal movement (e.g. parts of the Old Red Sandstone), yet perceptible difference in condition can be made out between beds of similar composition at the top of the series and near its base. The cemented or fossiliferous material is most commonly calcareous or siliceous. Limestones, which were originally loose accumulations of shells, fossils, &c., become compacted into firm rock in this manner; and the process often takes place with surprising ease, as for example in the deeper parts of coral reefs, or even in wind-blowed masses of shell detritus exposed merely to the action of the rain. The cementing substance may be regularly deposited in crystalline continuity on the original grains, where these were calcareous; and even in sandstones (such as Kentish Rag) a crystalline matrix of calcite often envelops the grains and is hard enough to be mistaken for the original sandstone. In limestone the grains of calcite do not dissolve, by forming new crystalline masses in the interior of the rock, usually also accelerates consolidation. Silica is less easily soluble in ordinary waters, but even this ingredient of rock may be replaced by a new one of great consequentic value. Sandstones are held together by an infinitesimal amount of colloid or cryptocrystalline silica; when freshly dug from the quarry they are soft and easily trimmed, but after exposure to the air for some time they become hard as their siliceous cement or siliceous glass passes into a rigid condition. Others contain fine scales of kaolin or of mica. Argillaceous materials may be compacted by mere pressure, like graphite and other slate minerals. Oides and carbonaceous rocks have been often associated in the same deposit, and the two are especially important as colouring matters. The red sands and Carboniferous limestones, for example, which are so abundant, contain small amounts of ferric oxide (haematite), which in a finely divided condition is a red clay and is called bentonite or montmorillonite. Limonite, on the other hand, makes rocks yellow or brown; oxides of manganese, asphalt and other carbonaceous substances are the cause of the black colour of many sediments. Bluish and green tints in shales and argillaceous rocks are due to fluor spar; while green is most frequently seen in rocks which contain glauconite or chlorite.

Metamorphic Rocks.—The metamorphic rocks, which form the third great subdivision, are even more varied than the igneous and the sedimentary. Many of them may be of nearly all kinds of the other two classes, their common characteristic being that they have undergone considerable alterations in structure or in mineral composition. The agencies of metamorphism (q.v.) are of two kinds—thermal and regional. In the former case contact with intrusive igneous masses, such as granite, laccolithes or dikes, have indurated and recrystallized the original rock. In the second case the actions are more complex and less clearly understood; it is evident that pressure and interstitial movement have had a powerful influence, possibly assisted by the rise of temperature. In thermal contact alteration the rocks are baked, indurated, and often in large measure recrystallized. In regional metamorphism recrystallization also goes on, but the final products are usually schists and gneisses. It is as a rule not difficult to distinguish the two classes of metamorphic rocks at a glance, and they may be conveniently be considered separately.

When a rock is contact altered by an igneous intrusion it very frequently becomes harder, more crystalline and more lustrous, owing to the development of many small crystals in its mass. Many altered rocks of this type were formerly called phyllites, hornfelses, hornfels (Hornfels) is often used by geologists to signify those fine grained, compact, crystalline products of thermal metamorphism. A shale becomes a dark argillaceous hornblende, full of tiny blebs of hornblende, which has imbibed all the water, and in many contact altered lavas the steam cavities are still visible, though their contents have usually entered into new combinations to form minerals which were not originally present. The minute structures, which may disappear, often completely, if the thermal alteration is very profound; thus small grains of quartz in a shale are lost or blend with the surrounding particles of clay, and the fine ground-mass of lavas is entirely reconstructed.

By recrystallization in this manner peculiar rocks of very distinct types are frequently formed. Thus shales may pass into cordierite rocks, or may show large crystals of andalusite (and chalcolite, Pl. IV., fig. 9), staurolite, garnet, kyanite and sillimanite. A considerable amount of mica (both muscovite and biotite) is simultaneously formed, and many kinds of rocks become mica schists. If the original rock was a sandstone, or measured, it may have been heated and altered so as to become a grey, yellow or greenish lime-silicate-hornblende, tough and splinterly, with abundance of augite, garnet, wollastonite and other minerals in which lime is an important component. A diabase or anadite becomes wollastonite, which in many cases has been split and enclosed into a new hornblende. A felsic rock will probably produce a quartz schist or a quartzite. If the rock was originally banded or foliated (as, for example, a laminated sandstone or a foliated calc-schist) this character may not be obliterated, and a banded hornfels is the product; fossils even may become metamorphosed and changed to other minerals, and in many contact altered lavas the steam cavities are still visible, though the contents have usually entered into new combinations to form minerals which were not originally present. The minute structures, which can be seen to disappear, especially completely, if the thermal alteration is very profound; thus shales are lost or blend with the surrounding particles of clay, and the fine ground-mass of lavas is entirely reconstructed.

In a few cases rocks are fused and in the dark glassy product minute crystals of spinel, sillimanite and cordierite may separate and be present. Shales are occasionally changed into felsic rocks, and felsic sandstones may be completely vitrified. Similar changes may be induced in shales by the burning of coal seams or even by an ordinary furnace.

There is also a tendency for interfusion of the igneous with the sedimentary rock. Granites may absorb fragments of shale or pieces of basalt. In that case hybrid rocks arise which have not the characters of normal igneous or sedimentary rocks. Such effects are said to have been exceeded in the cases of the Palisades of New Jersey, and felsic rocks have been said to have been fused and combined with the igneous (schists). Granite masses have been dissolved and redeposited in states of very low pressure and temperature, and the rocks thus formed are often metamorphosed in a distinct way. The region in which this process occurs is called a contact or a regional metamorphism.
PETROLOGY

The large white crystal is felspar, the smaller ones are nepheline having six-sided and four-sided sections. The dark mineral in the ground-mass is aegirine.

Fig. 1.—PHONOLITE, TEPLITZER SCHLOSSBERG, BOHEMIA (x 12).

A porphyritic clear crystal of leucite lies near the centre of the field; towards the margins are nesoscan crystals with clear centres and broad black edges. The dark spots are aegirine and aegirine-augite, and in the ground-mass small prisms of white nepheline may be seen.

Fig. 2.—LEUCITOPHYRE, RIEDEN, EIFFEL, GERMANY (x 15).

The rounded central crystal is leucite, showing zones of inclusions and well-marked cracks; below it is a dark-brown augite, and olivine occurs near the bottom of the field. There are numerous rectangular sections of plagioclase felspar. The dark ground-mass is partly vitreous.

Fig. 3.—LEUCITE-BASANITE, VESUVIUS (x 8).

A porphyritic rock with phenocrysts of white plagioclase felspar and of pale-brown augite and hypersthene in a fine ground-mass, partly glassy.

Fig. 4.—HYPERSTHENE-ANDESITE, ALWYN, CHEVIOTS, ENGLAND (x 10).

Two large crystals of augite above and below, and of olivine (right and left) lie in a crystalline ground-mass of plagioclase felspar, augite, and magnetite. The olivine has been altered to fibrous green serpentine, and the pseudomorphs show traces of the original cleavage cracks.

Fig. 5.—OLIVINE-BASALT, CRAIG-Lockart, EDINBURGH, SCOTLAND (x 10).

Felspar occurs towards the edges of the field and surrounds a cluster of diallage (with strong, dark, parallel lamination) and of olivine (covered with a black network of secondary magnetite).

Fig. 7.—OLIVINE-GABBRO, VOLPERS-Dorf, SILESIA (x 10).

In this rock the process of serpentinization, seen in the previous figure, is complete. No olivine remains, but a meshwork of magnetite indicates the position of the cracks in the original crystals.
**PETROLOGY**

**Fig. 1.** — **PEBBLY GRIT, BANFF, SCOTLAND (x 12).**

The white pebbles are quartz with irregular cracks and streaks of fluid inclusions. The matrix is a dark, semi-opaque mixture of clay and small sand-grains.

**Fig. 2.** — **VOLCANIC TUFF, ARTHUR'S SEAT, EDINBURGH (x 8).**

A fragmental volcanic rock with small lapilli of basalt; these are vesicular and contain little felspar crystals. Broken felspars also lie scattered through the rock.

**Fig. 3.** — **CRINOIDAL LIMESTONE, CARBONIFEROUS, CLIFTON, NEAR BATH, ENGLAND (x 10).**

The oolitic grains are round or oval, with concentric zoning; in their interior there is sometimes a shell fragment or other nucleus. The interstitial matrix is clear, granular, crystalline calcite.

**Fig. 4.** — **MARBLE, CARRARA, ITALY (x 8).**

A section of well-known statuary marble which consists entirely of calcite in small irregular crystals closely fitted together.

**Fig. 5.** — **OOLITIC CHERT (CAMBRIAN), SUTHERLANDSHIRE, SCOTLAND (x 15).**

This has been once an oolitic limestone, but the calcite has been entirely replaced by silica with perfect preservation of the oolitic structure.

**Fig. 6.** — **MYLONITE DURNESS, SUTHERLANDSHIRE (x 8).**

This well-banded rock was once a crystalline granite which has been greatly crushed by earth-movements, and has been ground down into a fine aggregate of quartz, felspar, and mica. The banding is due to internal flow under great pressure.

**Fig. 7.** — **SLATE, WADEBRIDGE, CORNWALL (x 20).**

A fine-grained clay rock with small clear spots of quartz and minute scales of mica, chlorite, &c. The parallel arrangement of the latter is the cause of cleavage. Obious dark lines cut across the rock and indicate the development of a secondary cross-cleavage or slip-cleavage.

**Fig. 8.** — **MICA-SCHIST, BLAIR-ATHOLL, PERTHSHIRE, SCOTLAND (x 32).**

A clay rock like the preceding one, but more metamorphic and coarsely crystalline. The clear spots are quartz and the bladed mineral between them is brown and white mica (biotite and muscovite).

**Fig. 9.** — **CHIASTOLITE-SLATE, SKIDDAW, CUMBERLAND (x 17).**

A clay rock affected by contact metamorphism attended by the production of needles of chiastolite, which have in transverse section a diamond-shape with dark enclosures at their centres and a dark cross radiating to their corners.
PETRONEI—PETRONEUS

will be visible. In gneisses these alternating folia are thicker and less regular than in schists; they are often lenticular, dying out rapidly. Gneisses also, as a rule, contain more felspar than schists do, and they are tougher and less fissile. Contortion or crumpling (P. L. 12, 13) is also frequent, and then the splitting faces are undulose or puckered. The origin of schistosity or foliation is not perfectly understood, but it is clear that in some cases it is due to pressure, acting in a direction perpendicular to the banding, and in others to a normal flow arranging the mineral particles while they are crystalizing.

Rocks which were originally sedimentary and rocks which were undoubtedly igneous are converted into schists and gneisses, and if originally of similar composition they may be distinguished from one another if the metamorphism has been great. A quartz-porphyry, for example, and a fine felspathic sandstone, may both be converted into a grey or pink mica-schist. Usually, however, the former will give a symplectic texture of schist and gneiss and gneisses. Often the metamorphism is progressive, and if the whole district occupied by these rocks be searched traces of bedding, of clastic structure, unconformability or other evidence may be obtained that we are dealing with a group of altered sediments. In other cases intrusive junctions, chilled edges, contact alteration or porphyritic structure may prove that in its original condition a metamorphic gneiss was an igneous rock. The last appeal is often to the chemist, for there are certain rock types which occur only as sediments, while others are found only among igneous masses, and, however advanced the metamorphism may be, it rarely modifies the chemical composition of the mass very greatly. Such rocks as andesite, diorite, talc schists, andalusite, cordierite, and aluminous shales have very definite chemical characters which distinguish them even when completely recrystallized.

The schists and gneisses are classified according to the minerals they contain. Their classification depends upon the type of composition. We have, for example, a group of metamorphic limestones, marbles, calc-schists and cipollins, with crystalline dolomites; many of these contain silicates such as mica, tremolite, diopside, and/or chlorite; and another group of calc-silicate gneisses which consist of calc-silicate rocks and mica schists, and are relatively common.

The graphic schists may readily be believed to represent sediments once containing coaly matter or plant remains; there are also schistose ironstones (haematite-schists), but metamorphic beds are very exceptional in the absence of fossils. In rocks of the igneous origin we may mention the silicic schists, the foliated serpentines (once ultrabasic masses rich in olivine), and the white mica-schists, porphyroblasts and banded halleflint, which have been derived from quartz porphyry, and acid porphyries and acid dacites. The mica-schists, however, are altered clays and shales, and pass into the normal sedimentary rocks through various types of phylite and mica-slates. They are among the most common metamorphic rocks; some of them contain minerals other than mica. The way in which the appearance and composition is very great, but they form a well-defined group not difficult to recognize, from the abundance of black and white micas and their thin, foliated, schistose character. As a rule, the grano-porphyry quartz-slates, together with the gneisses, which usually make their appearance in the vicinity of gneissose granite, and have presumably been affected by contact alteration. The mica-schists are frequently termed phyllites, and present a great variety of types differing in composition and in appearance. They contain one or more varieties of felspar, and usually mica hornblende or augite, often garnet or biotite, &c. and others of the same type. The hornblende and pyroxene gneisses are usually igneous rocks formed in the hornblende-granites and quartz-diorites. The metamorphic forms of dolerite, basalt and the basic igneous rocks differ in this respect from the gneisses, and the schists are replaced by dark green hornblende, with often epidote, garnet and biotite. These rocks have a well developed foliation, as the prismatic hornblendes lie side by side in parallel arrangement. The mica-schists, however, show no parallelism, but the hornblende and green schists belong to this group. Where they are least altered they pass through chloritic schists into sheared diabases, faser gabbros and other rocks which remain of the original igneous type but are metamorphosed.

PETRONEI, a 16th or 17th century fire-arm, defined by R. Barret (Theorique et Practice of Modern Warres, 1598) as a "horseman's pece." It was the fire-arm which developed on the one hand into the pistol and on the other into the carbine. The name petronei for petronal was given to the weapon which had been fired with the butt resting against the chest (petrandreste, Lat. postus) or because it was carried slung from a belt across the chest.

PETRONIUS (G.?1 Petronius Arbiter), Roman writer of the Neronian age. His own work, the Satirae, tells us nothing directly of his fortunes, position, or even century. Some lines of Sidonius Apollinaris refer to him and are often taken to imply that he lived and wrote at Marseilles. If, however, we accept the identification of this author with the Petronius of Tacitus, Nero's courtier, we must suppose either that Marseilles was his birthplace or, as is more likely, that Sidonius refers to the novel itself and that its scene was partly laid at Marseilles. The chief personages of the story are evidently strangers in the towns of southern Italy where we find them. Their Greek-sounding names (Encolpius, Ascylos, Giton, &c.) and literary training accord with the characteristics of the old Greek colony in the 1st century A.D. The Greek name Petronius has been applied to the Latin poet Petronius to Petronius, and the mention of him beside Menander by Macrobius, when compared with the absolute silence of Quintilian, Juvenal and Martial, seem adverse to the opinion that the Satirae was a work of the age of Nero. But Quintilian was concerned with writers who could be turned to use in the

1 The MSS. of the Satirae give no praenomen. Tacitus' Petronius is Gaius, though the elder Pliny and Plutarch call him Titus. The name Arbiter, given him by later writers, is not an ordinary cognomen; it may have been bestowed on him by contemporaries from the fact that his judgment was regarded as the criterion of good taste.
other era than that in which Nero's Tristia and Lucan's Pharsalia were fashionable poems. The reciting poet indeed is a feature of a later age also, as we learn from Martial and Juvenal. But we know from Tacitus that the luxury of the table, so conspicuous in Trimalchio's Banquet, fell out of fashion after Nero (Ann. 3, 55).

Of the work itself there have been preserved 134 sections of a narrative, in the main consecutive, although interrupted by frequent gaps. The name Satyræ, given in the best MSS., implies that it belongs to the type to which Varro, imitating the Greek Menippus, had given the character of a medley of prose and verse composition. But the string of fictitious narration by which the medley is held together is something quite new in Roman literature. This careless prodigal was so happily inspired in his devices for amusing himself as to introduce to Rome and thereby transmit to modern times the novel based on the ordinary experience of contemporary life—the precursor of such novels as Gib. Bar on and Roderick Random. There is no evidence of the existence of a regular plot in the fragments, but we find one central figure, Encolpius, who professes to narrate his adventures and describe all that he saw and heard, whilst allowing various other personages to exhibit their peculiarities and express their opinions dramatically.

The fragment opens with the appearance of the hero. Encolpius, who seems to be an itinerant lecturer travelling with a companion named Ascytus and a boy Giton, in a portico of a Greek town, in Campania. An admirable lecture is then given on the science of education, represented by a rival declamer, Agamemnon, who shifts the blame from the teachers to the parents. The central personages of the story next go through a series of questionable adventures, in the course of which they are often considerably excited and highly excited. One day or two after they are present at a dinner given by a freedman of enormous wealth, Trimalchio, who entertained with ostentatious and grotesque extravagance a number of men of his own rank but less prosperous. We listen to the ordinary talk of the guests about the weather, about the hard times, about the public games, about the education of their children. We recognize in an extravagant form the same kind of vulgarities and preposterous which the satirist of all experience has found to be the downfall and outcasts of the age.

Next day Encolpius separates from his companions in a fit of jealousy, and, after two or three days' sulking and brooding on his revenge, enters a picture gallery, where he meets with an old poet, who, after talking sensibly on the decay of art and the inferiority of the painters of the age to the old masters, proceeds to illustrate a picture of the capture of Troy by some verses on that theme. This ends in those who are walking in the adjoining colonnade driving the poet from the gallery. After a short stay, Encolpius finds he has fallen into the hands of some old enemies. They are shipwrecked, and Encolpius, Giton and the old poet get to shore in the neighbourhood of Crotone, where, as the inhabitants of the town are called by themselves the Trojans, they are considered the peculiar favourites of fortune. The fragment ends with a new set of questionable adventures, in which prominent parts are played by a beautiful enchantress named Circe, a priestess of Priapus, and a certain matron who leaves them her heirs, but attaches a condition to the inheritance; rich even Encolpius might have shrunk from fulfilling. If we can suppose the author of this work to have been animated by any other motive than the desire to amuse himself, it might be that of convincing himself, if that the world in general was as bad as he was himself. Juvenal and Swift are justly regarded as among the very greatest of satirists, and their estimate of human nature is nearly as unfavourable as that of Petronius; but their attitude towards mankind is, on the other hand, more enlightened and their real aim is the realism of disgust, not, like that of Petronius, a realism of sympathy. Martial does not cloy the vices of which he writes with cynical frankness. He is perfectly aware that they are bad, but feels that the reproach of the worst that can cast on any one. And, further, Martial, with all his faults, is, in his affections, his tastes, his relations to others, essentially human, friendly, generous, true. There is perhaps not a single sentence in Petronius which expresses or suggests the least contempt or sympathy with the existence of affection, conscience or honour, or even the most elementary goodness of heart.

1 For the whole question of possible predecessors and Petronius's relation to the extant Greek romances see W. Schmid, "Der griechische Roman" in Jahrbücher für das klass. Altertum, &c. (1894).

2 Petronius' testamento meo legata habere praeter libertos meos, hac conditione percipient que dedi, sic corpus meum in partes conciderint et eantate populo comedienti (141).
The work has reached us so fragmentary and mutilated a shape that we may of course altogether have missed the key to it; it may have been intended by its author to be a sustained satire, written in a vein of reserved and powerful irony, of the type realized in our modern Jonathan Swift. However, if we do not admit that, in the entire divorce of intellectual power and insight from any element of right human feeling, the work is an exceptional phenomenon in literature. For, as a work of original power, of humorous representation, and of intellectual imagination, the fragment is not without its piquancy, and it stirs up all the admiration which it has received. We recognize the arbiter elegantiarum in the admirable sense of the remarks scattered throughout it on education, on art, on poetry and on eloquence. There is a true feeling of nature in the description of a grove of plane-trees, cypresses and pines:

"Has inter ludebat aquis errantibus annis
Spumeus et querulo vexabat rore lapillos."

And some of the shorter pieces anticipate the tersenness and elegance of Carus, although the style longs for, and has not yet seen, so much of that with the view of parodying as of entering into rivalry with the poem of Lucian. In the epigram extemporized by Trimalchio late on in the banquet:

"Quod non expectes, ex transverso fit-
Homo, vir et actio in quod sese curat.
Quaer don nobis vina Falerna, puer,"

we have probably a more deliberate parody of the style of verses produced by the illustrious aspares to be in the fashion of the day. We might conjecture that the chief gift to which Petronius owed his success was that of being a bit of a charlatan. In the first of Petronius and his various guests, in the old poet, in the cultivated, depraved and moody Encolpius, in the Chrysis, Quattuors, Polycaste, &c., we recognize in living examples the play of those various social tendencies which have often been held to be inextricable from the development of great institutions, and which we consider as abstract qualities. Another gift he possesses in a high degree, which must have availed him in society as well as in literature—the gift of story-telling; and some of the stories which first appear in the Satyricon, e.g., that of the Marrantus of Ephesus—have enjoyed a great reputation in later times. His style, too, is that of an excellent talker, who could have discussed questions of taste and literature with the most cultivated men of any time as well as amused the most disinterested society of any time in their most reckless moods. One phrase of his is often quoted by many who have never come upon it in its original context, "Horatii curiosa felicitas."

AUTHORITIES—Until about 1850 only part of the Banquet of Trimalchio has been known to us, and other fragments of the work were known. The best MS. of this type is a Leiden MS., a copy by Scaliger of one which seems to have belonged to Cujacius. Marinus Statilius (see, however, Ellis, Journal of Philology, 12, p. 266) discovered at Trau in Dalmatia a copy of the whole Banquet, which was first published at Padua in 1664.

The important editions are (1) with explanatory notes: Burmann (Amsterdam, 1743, with Heinsius's notes); and, of the Cena only, Friesekeke (Leipzig, 1772, ed. by Lehrs, 4th ed., 1804), with notes (2) critical notes: Biecher (Berlin, 1862, 4th ed., 1904). Translations into German by Friedländer's edition (Cena only), into French by de Gueve (complete, in Garnier's Bibliothèque), into Spanish by de la Sagra (complete), and Boland (complete). Lexicon to Petronius by Seghede and Lommatzsch (Leipzig, 1898). Criticism, &c., in Haley, "Quaeest. Petron." (Harvard Studies, 1891); Collignon, Etude sur Pétrone (Paris, 1852); Emile Théophile, "Bouquets de la société romaine d'après Pétron" (Paris, 1892); Hirtzel, Der Dialog, ii. (Leipzig, 1895); Tyrrell, Latin Poetry (London, 1895); Norden, Antike Kunstpla (Leipzig, 1898); Henderson, Life and Principa of the Emperor Nero (London, 1893); Dild, Roman Society from the Earliest Times (London, 1905); and the various histories of Roman literature (especially Schanz, §§ 395 sqq.).

PETROPAVLOVSK—PETRUCCI

The work has reached us so fragmentary and mutilated a shape that we may of course altogether have missed the key to it; it may have been intended by its author to be a sustained satire, written in a vein of reserved and powerful irony, of the type realized in our modern Jonathan Swift. However, if we do not admit that, in the entire divorce of intellectual power and insight from any element of right human feeling, the work is an exceptional phenomenon in literature. For, as a work of original power, of humorous representation, and of intellectual imagination, the fragment is not without its piquancy, and it stirs up all the admiration which it has received. We recognize the arbiter elegantiarum in the admirable sense of the remarks scattered throughout it on education, on art, on poetry and on eloquence. There is a true feeling of nature in the description of a grove of plane-trees, cypresses and pines:

"Has inter ludebat aquis errantibus annis
Spumeus et querulo vexabat rore lapillos."

And some of the shorter pieces anticipate the tersenness and elegance of Carus, although the style longs for, and has not yet seen, so much of that with the view of parodying as of entering into rivalry with the poem of Lucian. In the epigram extemporized by Trimalchio late on in the banquet:

"Quod non expectes, ex transverso fit-
Homo, vir et actio in quod sese curat.
Quaer don nobis vina Falerna, puer,"

we have probably a more deliberate parody of the style of verses produced by the illustrious aspares to be in the fashion of the day. We might conjecture that the chief gift to which Petronius owed his success was that of being a bit of a charlatan. In the first of Petronius and his various guests, in the old poet, in the cultivated, depraved and moody Encolpius, in the Chrysis, Quattuors, Polycaste, &c., we recognize in living examples the play of those various social tendencies which have often been held to be inextricable from the development of great institutions, and which we consider as abstract qualities. Another gift he possesses in a high degree, which must have availed him in society as well as in literature—the gift of story-telling; and some of the stories which first appear in the Satyricon, e.g., that of the Marrantus of Ephesus—have enjoyed a great reputation in later times. His style, too, is that of an excellent talker, who could have discussed questions of taste and literature with the most cultivated men of any time as well as amused the most disinterested society of any time in their most reckless moods. One phrase of his is often quoted by many who have never come upon it in its original context, "Horatii curiosa felicitas."

AUTHORITIES—Until about 1850 only part of the Banquet of Trimalchio has been known to us, and other fragments of the work were known. The best MS. of this type is a Leiden MS., a copy by Scaliger of one which seems to have belonged to Cujacius. Marinus Statilius (see, however, Ellis, Journal of Philology, 12, p. 266) discovered at Trau in Dalmatia a copy of the whole Banquet, which was first published at Padua in 1664.

The important editions are (1) with explanatory notes: Burmann (Amsterdam, 1743, with Heinsius's notes); and, of the Cena only, Friesekeke (Leipzig, 1772, ed. by Lehrs, 4th ed., 1804), with notes (2) critical notes: Biecher (Berlin, 1862, 4th ed., 1904). Translations into German by Friedländer's edition (Cena only), into French by de Gueve (complete, in Garnier's Bibliothèque), into Spanish by de la Sagra (complete), and Boland (complete). Lexicon to Petronius by Seghede and Lommatzsch (Leipzig, 1898). Criticism, &c., in Haley, "Quaeest. Petron." (Harvard Studies, 1891); Collignon, Etude sur Pétrone (Paris, 1852); Emile Théophile, "Bouquets de la société romaine d'après Pétron" (Paris, 1892); Hirtzel, Der Dialog, ii. (Leipzig, 1895); Tyrrell, Latin Poetry (London, 1895); Norden, Antike Kunstpla (Leipzig, 1898); Henderson, Life and Principa of the Emperor Nero (London, 1893); Dild, Roman Society from the Earliest Times (London, 1905); and the various histories of Roman literature (especially Schanz, §§ 395 sqq.).

(W. Y. S.; W. C. Su.)
PETRUS AUREOLUS—PETTY

the highest bidders, or conferring them on his followers. A plot was made to murder him, but he discovered the conspiracy in time, and his own father-in-law, who had been leader of the movement, was put to death. In 1498 he prevented the outbreak of war with Florence over the possession of Montepulciano, which had been a bone of contention between the two cities for over a hundred years. His attitude towards Cesare Borgia was exceedingly astute; at first he assisted him, and obtained from him the favour of the French king the cession of Piombino; but having subsequently aroused the suspicions of Borgia, the latter attempted to suppress Petrucci by inviting him to the fatal meeting of Senigallia. The Sienese tyrant, however, did not fall into the trap, and although Borgia in 1502 obliged him to quit Siena, he returned two months later, more powerful than before. Petrucci supported Pisa in the war against Florence, but eventually, through the intervention of the pope and of the king of Spain, he made peace with the latter city, to which he gave back Montepulciano in 1512. As a reward for this action Pope Julius II. created his nephew cardinal. During his last days Petrucci abdicated his authority in favour of his son Borghese. He died at San Quirico di Osnana on the 21st of May 1512.

See Pecci, Memorie storico-critiche di Siena (Siena, 1755); U. G. Mondolfo, P. Petrucci signore di Siena (Siena, 1899).

PETRUS AUREOLUS (ORIO), scholastic philosopher and monk of the Franciscan order, lived in the latter half of the 13th century, and died in Paris in 1321 just after his appointment as archbishop of Aix. He was one of the first to attack the realist doctrines of Duns Scotus, and is interesting mainly as the precursor of William of Occam in his revival of Nominalism. His ability earned for him the titles of Doctor Facundus and Doctor Abundans.

PETTKENOFEN, AUGUST VON (1821-1889), Austrian painter, born in Vienna, was brought up on his father's estate in Galicia. Having decided to give up the military career on which he had started, he devoted himself to painting, taking for his subjects the simple scenes of the life on the dreary Puszta. His paintings are treasured for their fine qualities of colour, and for the sincerity with which the artist sets before us the uneventful melancholy life of Hungarian peasants and gipsies—without any theatrical paths or forced humour. He was the inventor of the Pettenkofen box, an appliance for dissolving and redistributing cracked or discoloured varnish without friction or the dangerous use of chemicals. He died in Vienna in 1889.

PETTKENOFER, MAX JOSEPH VON (1818-1901), Bavarian chemist and hygienist, was born on the 3rd of December 1818 at Lichtenheim, near Neuburg. He was a nephew of Franz Xaver Pettenkofen (1755-1850), who from 1823 was surgeon and apothecary to the Bavarian court and was the author of some chemical investigations on the vegetable alkaloids. He studied pharmacy and medicine, where he graduated M.D. in 1841. Having worked under Liebig at Giessen was appointed chemist to the Munich mint in 1845. Two years later he was chosen extraordinary professor of chemistry in the medical faculty, in 1853 he received the ordinary professorship, and in 1865 he became also professor of hygiene. In 1834 he retired from active work, and on the 10th of February 1901 he shot himself in a fit of depression at his home on the Sternberger See, near Munich. In his earlier years he devoted himself to chemistry, both theoretical and applied, publishing papers on the preparation of gold and platinum, numerical relations between the atomic weights of analogous elements, the formation of aventurine glass, the manufacture of illuminating gas from wood, the preservation of oil-paintings, &c. The reaction known by his name for the detection of bile acids was published in 1844.

PETTKENOFER gave vigorous expression to his views on hygiene and disease in numerous books and papers; he was an editor of the Zeitschrift für Biologie from 1865 to 1882, and of the Archiv für Hygiene from 1883 to 1894.

PETTICOAT, an underskirt, as part of a woman's dress. The Petticoat, i.e. "petty-coat" or small coat, was originally a short garment for the upper part of the body worn under an outer dress; in the Promptorium parvulum the Latin equivalent is tunica. It was both a man's and a woman's garment, and was in the first case worn as a small coat under the doublet and by women apparently as a kind of chemise. It was however, early applied to the skirt worn by women hanging from the waist, whether as the principal lower garment or as an underskirt. In the middle of the 17th century the wide breeches with heavy lace or embroidered ends worn by men were known as "petticoat breeches," a term also applied to the loose canvas or olskin overalls worn by fishermen.

PETTIE, JOHN (1839-1893), Scottish painter, was born in Edinburgh on the 17th of March 1839, the son of Alexander and Alison Pettie. In 1852 the family removed to East Linton, Haddingtonshire, and a portrait by the lad of the village carrier and his donkey overcame his father's objections to art as a career for his son. When sixteen he entered the Trustees' Academy in Edinburgh, working under Robert Scott Lauder, W. Q. M'Whirter, W. M'Taggart, Peter Graham, Tom Graham and G. P. Chalmers. His first exhibits at the Royal Scottish Academy were "A Scene from the Fortunes of Nigel"—one of the many subjects for which he sought inspiration in the novels of Sir Walter Scott—and two portraits in 1858, followed in 1859 by "The Prison Pet." To the Royal Academy in 1860 he sent "The Armourers"; and the success of this work and of "What d'ye Lack, Madam?" in the following year, encouraged him to settle in London (1862), where he joined Orchardson. In 1866 he was elected an Associate of the Royal Academy, and in 1874 received full academical honours in succession to Sir Edwin Landseer. His diploma picture was "Jacobites, 1745." Pettie was a hard and rapid worker, and, in his best days, a colourist of a high order and a brilliant executant. In his early days he produced a certain amount of book illustration. His connexion with Good Words began in 1861, and was continued till 1884. With J. MacWhirter he illustrated The Postman's Bag (Strahan, 1862), and Wordsworth's Poetry for the Young (Strahan, 1863).

His principal paintings, in addition to those already mentioned, are "Cromwell's Saints" (1862); "The Trio" (1863); "George Fox refusing to take the Oath" (1864); "A Drunken Courtmartial" (1865); "The Arrest for Witchcraft" (1866); "Treason" (1867, now in the Mappin Art Gallery, Sheffield); "Tussie with a Highland Smugger" (1868); "The Sally" (1870); "Terms to the Besiegled" (1872); "The Flag of Truce" (1873); "Ho! Ho! Old Noll" and "A State Secret" (1874); "A Sword and Dagger Fight" (1877); "The Death Warrant" (1879); "Monmouth and James II." (1882); "The Vigil" (1884, in the Chantrey Collection, National Gallery of British Art); "Challenged" (1885); The Chieftain's Candlesticks" (1886); "Two Strings to Her Bow" (1887); "The Highland and the Lowland"; Charles Wicklamb as David Garrick (1888); and "The Ultimatum" and "Bonnie Prince Charlie" (1892). Pettie died at Hastings on the 21st of February 1893. In 1894 a selection of his work was included in the Winter Exhibition of the Royal Academy. His portrait by himself is in the Tate Gallery.

JOHN PETTIE, R.A. (London, 1908), by his nephew Martin Hardie, gives the story of his life, a catalogue of his pictures, and fifty reproductions in colours.

PETTY, SIR WILLIAM (1623-1687), English statistician and political economist, born on the 26th of May 1623, was the son of a clothier at Romsey in Hampshire, and received his early education at Romsey Grammar School. About the age of fifteen he went to Caen (Normandy), taking with him a little stock of merchandise, on which he traded, and so maintained himself whilst learning French, improving himself in Latin and Greek, and studying mathematics and other sciences. On his return to England he seems to have had for a short time a place
PETTY-OFFICER—PETWORTH 337

in the royal navy. He went abroad again in 1643, and remained for three years in France and the Netherlands, pursuing his studies. In Paris he read Vesalius with Hobbes, who was then preparing his Tractatus opticus, and it is said that Petty drew the diagrams for him. In 1647 Petty obtained a patent for the invention of double writing, i.e. a copying machine. In politics he espoused the side of the parliament. His first publication was a letter to Samuel Hartlib in 1648, entitled Advice for the Advancement of some Particular Parts of Learning, the object of which was to recommend such a change in education as would give it a more practical character. In the same year he took up his residence at Oxford, where he was made deputy professor of anatomy, and where he gave instruction in that science and in chemistry. In 1649 he obtained the degree of doctor of physic, and was soon after elected a fellow of Brasenose College. He gained some notoriety in 1650 by restoring to life a woman who had been hanged for infanticide. In 1651 he was made professor of anatomy at Oxford, and a Doctor of Medicine at Gresham College. In 1652 he went to Ireland, having been appointed physician to the army in that country. In 1654, observing that the admeasurement and division of the lands forfeited in 1641 and granted to the soldiers had been “most inefficient and absurdly managed,” he entered into a contract to execute a fresh survey, which he completed in thirteen months.1 By this he gained £5000, and part of the money he invested profitably in the purchase of soldiers’ debentures. He thus became possessor of so large a domain in the county of Kerry that, according to John Aubrey, he could behold from Mt Mangerton 50,000 acres of his own land. He set up ironworks in that neighbourhood, opened lead-mines and marble- quarries, established a pilchard fishery, and commenced a trade in timber. Besides the office of commissioner of distribution of the lands he had surveyed, he held that of secretary to the lord-lieutenant, Henry Cromwell, and was also during two years clerk of the council. In January 1658 he was elected to Richard Cromwell’s parliament as member for West Looe in Cornwall. After the Restoration he returned to England and was favourably received and knighted by Charles II., who was “much pleased with his ingenious discourse,” and who, it is said, intended to create him earl of Kilmore. He obtained from the king a new patent constituting him surveyor-general of Ireland. In 1663 he attracted much notice by the success of his invention of a double-botomed ship, which twice made the passage between Dublin and Holyhead, but was afterwards lost in a violent storm. He was one of the first members of the Royal Society, and sat on its council. He died in London on the 16th of December 1667, and was buried in the church of his native place. His will, a curious and characteristic document, is printed in Chalmers’s Biographical Dictionary.

His widow, Elizabeth (d. 1708), daughter of Sir Hardress Waller (1604–1666), the Irish Cromwellian soldier and regicide, was created Baroness Shelburne by James II. in 1688; and her two sons were successively created earls of Shelburne, but on their death without issue the Petty estates passed to their sister, Anne, and after her marriage to the 1st earl of Kerry the Shelburne title was revived in her son’s favour (see under Lansdowne, 1st Marquess).

Petty’s Irish survey was based on a collection of social data which entitles him to be considered a real pioneer in the science of comparative statistics. He was also one of the first in whom we find a tendency to a view of industrial phenomena which was at variance with the then dominant mercantilist ideas, and he exhibits a statesmanlike sense of the elements in which the strength of a nation really consists. Rocher names him as having “hated the Plow and the Plowman” and as urging in his work on the agriculture of Ireland, published in 1670, that the one of which he had been injured by a fire in 1711, are preserved in the Public Record Office, Dublin.

PETTY-OFFICER, the title in the navy of a large number of minor (Fr. petit, small) officers, of less than commissioned or warrant rank—such as the master-at-arms, sailmaker, caulker, armourer, cook, &c. They were originally named, and removable, by the captain.

PETUNIA, in botany, a genus of plants belonging to the natural order Solanaceae and containing about 16 species, chiefly South American (southern Brazil and Argentina). The garden forms are derived from the white-flowered P. nyctaginiflora and the violet- or purple-flowered P. violacea. The varieties of petunia, especially the double forms, make admirable specimens for pot culture.

Named or specially fine varieties are propagated by cuttings taken from stock plants kept through the winter in a dry warm shed, and moved into a brisk moist heat in early spring; the young shoots are planted in pans or pots filled with sandy soil, and, aided by being stood in bowler hats, are allowed to make a sufficient growth before being put singly into pot-hpots, and when once established are gradually hardened off, and afterwards reported as required. The shoots should be topped to make bushy plants, and their tops may be utilized as cuttings. The single varieties are raised from seeds sown in light sandy soil in heat, in the early spring, and very slightly covered. The plants need to be pricked out or potted off as soon as large enough to handle. Good strains of seeds supply plants suitable for bedding; but, as they do not reproduce themselves exactly, any sorts particularly required must be propagated, like the double ones, from cuttings.

PETWORTH, a market town in the Horsham parliamentary division of Sussex, England, 55 m. S.S.W. from London by the London, Brighton & South Coast railway. Pop. (1901), 2593. The church of St Mary is Perpendicular, and contains numerous memorials of members of the Percy family and others. Petworth House, situated in a beautiful park, dates from the 18th century, and contains a magnificent collection of pictures. At Bignor in the neighbourhood are remains of an important and splendidly adorned Roman villa.

The first mention of Petworth (Pearlingwyth, Petorde, Peteorde, Petowt, Petworth, Pyttheworth, Petworth) occurs in a grant by Eardwulf, king of Northumbria, to St Peter’s Church, about 791. In the time of Edward the Confessor Petworth was an alodial manor held by his queen Edith, and in 1068 Robert Fitz-Tebald held it of Roger Montgomery, earl of Shrewsbury. It then included a church and a mill, and was rated at nine hides.

Through Queen Adelisa, Petworth came first into the hands of

1 The survey executed by Petty was, somewhat whimsically, called the “Down Survey,” because the results were set forth on maps; it is called by that name in Petty’s will. He left in MS. a full account of the proceedings in connexion with it, which was edited by Sir Thomas A. Larcom for the Irish Archæological Society in 1771. The maps, some of which were injured by a fire in 1711, are preserved in the Public Record Office, Dublin.
her steward, Reginald de Wyndor, and was afterwards given to her brother Josceline, who held it of the honour of Arundel. Josceline married Agnes de Percy and assumed the surname of Percy. The honour and manor of Petworth followed the descent of this family until 1708. In 1377 Henry Percy was created earl of Northumberland. The only daughter of the last earl married Charles, duke of Somerset, in 1682, and Petworth descended through their daughter Catherine to the earls of Egremont. The adopted son of the third earl was created Baron Leconfield in 1859.

PEUTINGER KONRAD (1465–1547), German humanist and antiquarian, was born at Augsburg. In 1497 he was town clerk of his native place, and was on intimate terms with the emperor Maximilian. He was one of the first to publish Roman inscriptions, and his name remains associated with the famous Tabula Peutingeriana (see MAP), a map of the military roads of the western Roman Empire, which was discovered by Konrad Celtis, who handed it over to Peutinger for publication. Peutinger also edited the Historia Gothorum of Jordanes, and the Historia gentis Langobardorum of Paulus Diaconus.

The Tabula peutingeriana was first published as a whole by F. de Schyeb (1753); later editions by E. Desjardins (1869–1873), C. Miller (1888); see also E. Paulus, Erklärung der Peutinger Tafel (1867); and Teuffel-Schwabe, Illst. of Roman Literature (Eng. trans., 1900).

PEVENSEY, a village in the Eastbourne parliamentary division of Sussex, England, 65 m. S.S.E. from London by the London, Brighton & South Coast railway. Pop. (1891), 469. The village is a member of the Cinque Ports, but the sea has receded a mile from it in historic times. The outer wall, with solid towers, of the celebrated castle, is of Roman construction, and originally enclosed a complete oval; it is generally considered to have enclosed the strong town of Anderida. Within rise the fine ruins, principally of the 13th century, but in part Norman, of the castle proper, with a keep and four massive round towers. The church of St Nicholas, close to the castle, shows beautiful Early English work. It has been supposed that Pevensey was the scene of the landing of Caesar in 55 B.C., but the question is disputed.

The name of Pevensey (Paevensiell, Pevensel, Pevenes, Peemsy) first occurs in a grant of land there by the south Saxon Duke Berthwold to the abbey of St Denis in 795. In later Saxon times, at least by the reign of Edward the Confessor, it was a royal borough and had a harbour and a market. Its early importance was due to its fencible port. It was the landing place of William the Conqueror, it was the capital of a dukedom, and was the capital of the county of Sussex, which was granted by William to the earl of Mortain and subsequently became the Honour of the Eagle. Some time before the reign of Edward I, the town of Pevensey was made a member of Hastings and shared the liberties of the Cinque Ports, but apart from them it possess no charter. It was governed by a bailliff and twelve jurats, elected annually, until by an act of 1883 it ceased to exist as a borough. Its seal dates apparently from the reign of Henry III. The gradual decline of Pevensey was complete in the 15th century and was caused by the recess of the sea and consequent loss of the harbour.

PEW (Mid. Eng. pew, through O. Fr. puye, pai, mod. puy, in the sense of hill, cf. appuyer, to lean against; from Lat. podium, a high place, balcony; Gr. zòkhos, pedestal, ρόθος, foot), a term, in its most usual meaning, for a fixed seat in a church, usually enclosed, slightly raised from the floors, and composed of wood framing, mostly with ornamented ends. Some bench ends are certainly of Decorated character, and some have been considered to be of the Early English period. They are sometimes of plain oak board, 2½ to 3 in. thick, chamfered, and with a necking and finial generally called a poppy head; others are plainly panelled with bold cappings; in others the panels are ornamented with tracery or with the linen pattern, and sometimes with running foliage. The large pews with high enclosures, curtains, &c., known familiarly as "horse-boxes," and common in English parish churches during the 18th and early part of the 19th centuries, have nearly all been cleared away. The parish church of Whityby, in Yorkshire, is perhaps the best surviving example of an unaltered interior.

The Latin word podium was particularly applied to a balcony or parapet next to the arena in the Roman theatre where the emperor and other distinguished persons sat. According to Du Cange, a pew *poeum* was a seat, or a bench *subsidium* for the minor canons at a church in Lyons (1432), and also for a kneeling stool in a monastic church. The word "pew" in English was often used for a stall for the minister, for a bishop's throne, or for a cushioned seat of value. In some cases medieval churches was usually open, mats being sometimes provided for kneeling, and if any fixed seats were provided these would be for the patrons of the church or for distinguished people. The term "pew" for a church bench, however, seems to have been reserved for women, as is seen in Piers Plowman, ch. vii. 144. "Among wyves and wedowes am i wyoned sitte yeaparoked in putes." They did not come into general use till the middle of the 13th or beginning of the 16th century (see Caxton, Peter Le Maistre of the lion, pp. 62 and 133). Over the few seats thus allotted dispute arose and attempts were made to appropriate them. Thus the constitutions for the synod of Exeter, drawn up by Bishop Peter Quivell in 1287, forbade one "to come any sitting in the church as his own... Whoever first comes to pray, let him take what place he wishes in which to pray."

At common law all seats in a parish church are for the common use of all the parishioners, and every parishioner has a right to a seat without paying for it. The disposition of the seats is in the discretion of the churchwardens acting for the ordinary for the purpose of orderly arrangement (as to the exercise of this discretion see Reynolds v. Monckton, 1841, 2 M. & R. 384), and this can be exercised in cases where all the seats are free (Asher v. Calkraft, 1887, 18 Q.B.D. 695). The right to a seat does not belong to a non-parishioner. As against the assignment and disposition of seats by the ordinary, acting through the churchwardens, two kinds of appropriation can be set up (a) by the grant of a faculty by the ordinary, and (b) by prescription, based on the presumption of a lost faculty. Such faculties are rarely granted now; they were formerly common; the grant was to a man and his family "so long as they remain inhabitants of a certain house in the parish"; the words "of a certain house" are now usually omitted. The claim to a pew by prescription must be in respect of a house in the parish; the right is subject to the burden of repairing the pew; it is not an easement, nor does the Prescription Act 1832 apply to it (see for the whole subject of a claim by prescription Phillips v. Halliday, 1891, A.C. 228). The letting of pews in parish churches became common in the 16th century, but there are some earlier instances of the use, for example, at St. Andrews, Bristol, in 1565 (Chesham, The Bristol and Gloucester Archaeol. Ass., vol. xv., 1890–1891). The taking of pew rents in parish churches is illegal (Lord Stowell, in Walter v. Gunner, 1765, 3 Hag. Consist. 817); but under the various Church Building Acts seats may be let and rents charged to pay the salary of the minister, &c.

See A. Heales, History and Law of Church Seats and Pews (1872); Phillimore, Eccles. Law (1896), ii. 1424 seqq.

Pewter, a general name used to denote a number of alloys of various metals in diverse proportions, the sole common feature of which lies in the fact that tin is always the chief constituent. The etymology of the word is doubtful, but it is probably an English modification of *speller*, which was adopted with more or less local alteration by the continental European nations, who at an early period were eager purchasers of the ware, becoming *peytier* in Dutch, *pèsteen* or *pètse* in French, *pezione* in Italian and *pelere* in Spanish. Roman pewter, the oldest known which has been disinterred at various places in England and elsewhere, was composed of tin and lead alone, for the occasional traces of iron are believed to be accidental, in proportions which, though varying considerably, group themselves around two definite formulæ, one containing 71.5 parts of tin to 28.8 of lead, the other 78.2 of tin to 21.7 of lead, or one libra of tin to 43 and 3 uncia of lead respectively. On the European continent in the middle ages, some ten centuries later than the supposed date of the Roman pewter found in Britain, when we first get definite records of the composition of pewter, lead remained the chief, if not the only secondary ingredient. In 1437 the pewterers of Montpelier added 4 parts of lead to 6 of tin,
when making dishes and porringer 10 parts of lead to 0 of tin for salt-cellers and ewers; those of Limoges used a parts of lead to 1 of tin at Nuremberg in 1576 it was ordained that not more than 1 lb of lead should be mixed with every 10 lb of tin; in France during the 18th century a limit of 15% of lead was imposed, while at the present time 16-5% with a margin of 1-5 for errors is regarded as safe for the storage of wine and consequently legal.

In England the earliest known ordinances for the regulation of the craft were drawn up in 1348 and received the approval of the mayor and aldermen. From them we learn that for rounded vessels lead might be mixed with the tin in the proportion of 26 lb to each hundredweight, though this quantity appears to have been found excessive, since in 1531 a pewterer was punished because his alloy contained more than 16 lb to the hundredweight, unless this be a clerical error in the contemporary records of the Pewters' Company. Articles made of this material were to be known as "vessels of tyn" and the alloy soon came to be known as "ley." Another formula, however, authorized in the same document, would appear to have been at that time an exclusively English secret, to which was presumably due the universal recognition of the superiority of the island wares which is so notable a fact in the history of pewter. It was known as "fyn peater" and used for dishes, saucers, platters, chargers, and for all "things that they make square," such as cruets, chisimatories, &c., which owing either to the rough usage they would be submitted to, or to the sharpness of their angles, called for greater toughness in the material. The recipe for this alloy as originally propounded was as much brass to the tin as it would receive of its nature, but the lack of precision in this perhaps rendered it difficult to distinguish accidental variations from deliberate adulteration, and in 1474-1475 it was resolved that 26 lb of brass must be mixed with every hundredweight of tin. The penalties for infringement of the rules were severe and frequently enforced, but to 100 years or more of them alterations and improvements crept in. The chief and perhaps the earliest of these was the addition of a certain proportion of bismuth, or as it was then called "tin glass." When this was first used it is not recorded, but by 1561 it was accepted as a matter of course; in 1630 a maker "was found in fault for not sufficiently tempering his metal with tin glass"; and in 1653 it was ordered that 3 lb weight of tin glass at least must be mixed with every 100 lb of tin. Antimony was subsequently introduced—though there is no mention of it in the records of the Pewters' Company—sometimes alone as in tin and temper (1-6 to 150 parts) and trifle (17 parts to 83 of tin), sometimes with other metals as in hard metal (96 parts of tin, 8 of antimony and 2 of copper), a mixture very closely resembling that still used under the name of "British metal," and in plate pewter (100 parts of tin, 8 of antimony, 4 of copper and 4 of bismuth). The wares were originally fashioned in two ways, by hammering or by casting. The articles worked in each were strictly differentiated, the former, who worked in fine pewter, being known as Sadware men, the latter who used "ley" as Hollow-ware men. A third class, known as Triflers, from the alloy they were limited to, probably at first only manufactured such small articles of domestic use or ornament as did not definitely fall under either of the other headings, but from an authorized list of wares, drawn up by a committee of Triflers in 1612, it is clear that the barrier between them and the Hollow-ware men had been largely broken down. Another method of working pewter which seems to have been introduced later, and never followed to any great extent, was spinning, by which the vessel was shaped in a mould on a wheel by the mere pressure of a blunt tool, the softness of the metal allowing of its flowing sufficiently for this purpose.

Pewter first appears in history in 1074, when a synod at Rouen permitted pewter to be a substitute for gold or silver in church vessels, a concession accepted also at Winchester two years later, again withdrawn in 1175, but once more tacitly adopted some twenty years after. The records of its domestic use commence with the caldrons employed for boiling the meat at the coronation of Edward I. in 1274, though we gather that the trade was even then flourishing in Paris and Bruges, whence during the following century it extended to Augsburg, Nuremberg, Poitiers, Mons and other continental centres. Confined at first to the more wealthy classes, we can trace as time goes on its extension lower and lower in the social scale, until at the end of the 17th century its use was almost universal. Thenceforward its vogue steadily declined. The growing cheapness of glass and chinaware and the invention of more showy metals brought upon it by degrees the fatal stigma of vulgarity, until with very few exceptions its manufacture entirely ceased.

Artistically, pewter was at its best when its makers were least conscious of the art revealed in it, thinking more of the durability and appropriateness to purpose of their wares than of their decorative qualities. Though intentionally ornamental vessels may be found earlier, it was not until the 18th century that the pewterers set themselves to slavishly copying the designs and methods of the silversmiths, whether suitable to their material or not, and thereby undoubtedly hastened their own downfall.

Of recent years pewter has taken its place among the articles sought after by collectors, and its cost has so materially and rapidly increased that the manufacture of vessels, guaranteed of course genuinely antique, bids fair to become once more a paying industry. Unfortunately the various enactments compelling each maker to stamp his ware with a definite touchmark seem at all times to have been very generally evaded or ignored, and experience alone is therefore the only safe guide to distinguishing new from old.

PÉZENAS, a town of southern France, in the department of Hérault, 33 m. W.S.W. of Montpellier on the southern railway. Pop. (1906), 6432. The commerce in cognac, spirits and wines is so important that the prices current for these at the weekly sales are registered throughout the wine marts of France and Europe. There is a handsome monument to Mollière, who lived at Pézénas several years and produced his first plays there in 1635 and 1636. A gateway (17th century) and old mansion of the 15th and 16th centuries are of interest.

Pézenas (Piscennae) was founded by the Gauls. In the 10th century it became the capital of a countship subsequently held by important families including those of Montmorency, Condé and Conti. In the 17th century the town was on several occasions the meeting place of the estates of Languedoc.

PFAFF, JOHANN FRIEDRICH (1765–1829), German mathematician, was born on the 22nd of December, 1765 at Stuttgart. He received his early education at the Carlsschule, where he met F. Schiller, his lifelong friend. His mathematical capacity was early noticed; he pursued his studies at Göttingen under Abraham Gotthelf Kästner (1710–1800), and in 1787 he went to Berlin and studied practical astronomy under J. E. Bode. In 1788 Pfaff became professor of mathematics in Helmstedt, and so continued until that university was abolished in 1810. From that time till his death on the 21st of April, 1825 he held the chair of mathematics at Halle. Pfaff's researches bore chiefly on the theory of series, to which he applied the methods of the so-called combinatorial school of German mathematicians, and on the solution of differential equations. His two principal works are Disquisitiones analyticae maxime ad calculum integralem et doctrinam serierum gerrmentium pertinentes, in 12 vol., 1814, and "Methodus generalis, aequaliones differentiarum, particularum, necon equationes differentiales vulgares, utrasque primi ordinis inter quotunque variabiles, complete integrandi," in ABB. D. BERL. ACAD. (1814–1815). The former work contains Pfaff's discussion
PFALZBURG—PFTORTA

of a certain differential equation which generally bears his name, but which had originally been treated in a less complete manner by L. Euler (see Differential Equations). The latter work contains an important addition to the theory of partial differential equations as it had been left by J. L. Lagrange.

His brother, Johann Wilhelm Andreas Pfaff (1776-1853), was professor of pure and applied mathematics successively at Dompert, Nuremberg, Würzburg and Erlangen. Another brother, Christian Heinrich Pfaff (1773-1852), graduated in medicine at Stuttgart in 1793, and from 1801 till his death was professor of medicine, physics and chemistry at the university of Kiel.

PFALZBURG, a town of Germany, in the imperial province of Alsace-Lorraine, lies high on the west slopes of the Voges, 25 m. N.W. of Strasbourg by rail. Pop. (1903), 3776. It contains an Evangelical and a Roman Catholic church, a synagogue and a teachers' seminary. Its industries include the manufacture of gloves, straw hats and liqueurs, and also quarrying.

The principality of Pfalzburg, of which this town was the capital, originally a part of Luxembourg, afterwards belonged in turn to the bishop of Metz, the bishop of Strasbourg and the duke of Lorraine, and passed into the possession of France in 1661. The town was of importance as commanding the passes of the Voges, and was strongly fortified by Vauban in 1680. The works resisted the Allies in 1814 and 1815, and the Germans for four months in 1870, but they were taken on the 12th of December of that year. They have since been razed.

PFEIFFER, FRANZ (1815-1868), German scholar, was born at Bettlach near Soleure on the 27th of February 1815. After studying at the university of Munich he went to Stuttgart, where in 1846 he became librarian to the royal library. In 1856 Pfeiffer founded the Germania, a quarterly periodical devoted to German antiquarian research. In 1857, having established himself in the latter same year, he engaged in the study of German medieval literature and philology, and he was appointed professor of these subjects at the university of Vienna; and in 1866 he was made a member of the Imperial Academy of Sciences. He died at Vienna on the 29th of May 1868.

Among the many writings edited by him may be mentioned the Barlaam and Josaphat of Rudolf von Ems (1843), the Edelestein of Ulrich Boner (1844), Die deutschen Mystiker des 14. Jahrhunderts (1845-1857; new ed., 1906), the Buch der Natur of Konrad von Megenberg, a 14th-century writer (1861), Die Predigten des Berthold von Regensburg (1862), and the poems of Walther von der Vogelweide (1864; 6th ed. by K. Bartsch, 1880). Of his independent work the most important is seiner durch Gebiete der Literaturgeschichte. Ober Wesen und Bildung der höfischen Sprache in mittelhochdeutscher Zeit, Der Dichter des Nibelungenliedes, Forschungen und Kritiken auf dem Gebiete des deutschen Altlietums, and Alliedeutsches Umgangbuch. A Latin translation of the first is in Ubersicht der Fürstenfahrt nach Freiherrn von Lassburg, edited by Franz Pfeiffer (1870).

PFEIFFER, IDA LAURA (1797-1858), Austrian traveller, daughter of a merchant named Reyer, was born at Vienna on the 14th of October 1797. In 1820 she married Dr Pfeiffer, a lawyer of Lemberg, who subsequently incurred official persecution and was reduced to poverty. In her later life Mme Pfeiffer devoted her limited means to travel. In 1842 she visited Palestine and Egypt, and published an account of her journey in Reise einer Wienerin in das Heilige Land (Vienna, 1843). In 1845 she set out to Scandinavia and Iceland, describing her tour in two volumes, Reise nach dem skandinavischen Norden und der Insel Island (Pest, 1846). In 1846 she started on a journey round the world, visiting Brazil, Chile and other countries of South America, Tahiti, China, India, Persia, Asia Minor and Greece, and reaching home in 1848. The results were published in Eine Frauenfahrt um die Welt (Vienna, 1850). In 1851 she went to England and thence to South Africa, intending to penetrate into the interior of this unexplored country, but she proceeded to the Malay Archipelago, spending eighteen months in the Sunda Islands and the Moluccas. After a visit to Australia, Madame Pfeiffer proceeded to California, Oregon, Peru, Ecuador, New Granada, the Missions Territory, and north again to the Great Lakes, reaching home in 1854. Her narrative, Meine zweite Weltreise, was published at Vienna in 1856. In May of the same year she set out to explore Madagascar, where at first she was cordially received by the queen. But she unwittingly allowed herself to be involved in a plot to overthrow the government, and was expelled. She died at Vienna on the 27th of October 1858.

The Reise nach Madagascar was issued in 1861 (Vienna), with a biography by her son.

PFEIFER, OTTO (1839-1908), German Protestant theologian, was born at Stetten near Cannstadt in Württemberg on the 1st of September 1839. From 1857 to 1861 he studied at Tübingen under F. C. Baur; and afterwards in England and Scotland. He then entered the ministry, became rector at Tübingen, and for a short time held a pastorate at Heilbronn (1868). In 1870 he became chief pastor and superintendent at Jena and soon afterwards professor ordinarius of theology, but in 1875 he was called to the chair of systematic theology at Berlin, having made his name by a series of articles on New Testament criticism and Johannine and Pauline theology, which appeared in Adolf Hilgenfeld's Zeitschrift für wissenschaftliche Theologie, and by his Der Paulinismus, published in 1873 (2nd ed., 1890; Eng. trans., Paulinism: a Contribution to the History of Primitive Christian Theology, 2 vols., 1873, &c.). The Urchristentum, seine Schriften und Lehren, in geschichtlichem Zusammenhang beschrieben was published in 1878 and considerably enlarged for a second edition in 1902 (Eng. trans., 1906). In 1890 appeared The Development of Theology since Kant, and its Progress in Great Britain since 1825, which was written for publication in England. A more elaborate work was his Religionsphilosophie auf geschichtlichen Grundlage (1878; 2nd ed., enlarged, 1883-1884; Eng. trans., from 2nd German ed., The Philosophy of Religion on the Basis of its History, 4 vols., 1886-1888). "The Influence of the Apocalypse Paul on the Development of Christianity" was the title of a course of Hibbert Lectures given in London in 1888. In 1894 he delivered the Gifford Lectures at Edinburgh, the subject being "The Philosophy and Development of Religion." His later publications included: The Early Christian Conception of Christ (1903), Die Entstehung des Christentums (1905; Eng. trans., 1906), Religion und Religionen (1906; Eng. trans., 1907), and Die Entstehung des Christentums (1907). He died on the 18th of July 1908, at Gross Lichterfelde, near Berlin. In New Testament criticism Pfleiderer belonged to the critical school which grew out of the impulse given by F. C. Baur. But, like other modern German theologians, he showed a greater disposition to compromise. All his work shows a judicial tone of mind, and is remarkable for the charm of its style.

Pfeifer's younger brother EDMUND (1842-1904) distinguished himself both in philosophy and theology. He too entered the ministry (1864) and during the Franco-German War served as army chaplain, an experience described in his Erlebnisse eines Feldgeistlichen (1890). He was afterwards appointed professor ordinarius of philosophy at Kiel (1873), and in 1878 he was elected to the philosophical chair at Tübingen. He published works on Leibnitz, empiricism and scepticism in Hume's philosophy, modern pessimism, Kantian criticism, English philosophy, Heraclitus of Ephesus and many other subjects.

PFORTA, or Schulpforta, formerly a Cistercian monastery dating from 1140, and now a celebrated German public school. It is in the Prussian province of Saxony, on the Saale, 2 m. S.W. of Naumburg. The remains of the monastery include the 13th century Gothic church, recently restored, the Romanesque chapel (13th century) and other buildings now used as dormitories, lecture rooms, &c. There is also the Fürstenhaus, built in 1735. Schulpforta is 22 miles from the nearest train station, and is reached by Maurice duke, and later elector, of Saxony, the two others being at Grimma and at Meissen. The property of the dissolved monastery provided a good revenue for the new educational foundation, which now amounts to about £15,000 a year. Free education is provided for 140 boys, the total number of pupils being 185. After being in the possession of Saxony, Pfortz passed to Prussia in 1815, and since this date the school has been entirely reorganized.
PFORZHEIM—PHAEDRUS

PFORZHEIM, a town of Germany, in the grand duchy of Baden, at the confluence of the Nagold and the Enz, on the northern margin of the Black Forest, 19 m. S.E. of Karlsruhe by rail, and at the junction of lines to Wildbad and Eutingen. Pop. (1895), 33,345; (1905), 39,795, most of whom are Protestants. Its most interesting buildings are the old palace of the margraves of Baden, and the Schlosskirche, the latter an edifice of the 13th-15th centuries, containing the tombs and monuments of the margraves. Pforzheim is the chief centre in Germany for the manufacture of gold and silver ornaments and jewelry, an industry which gives employment to about 22,000 hands, besides which there are iron and copper works, and manufactures of chemicals, paper, leather, machinery, &c. A brisk trade is maintained in timber, cattle and agricultural produce. Pforzheim (Porta Hercyniae) is of Roman origin. From about 1300 to 1505 it was the seat of the margraves of Baden. It was taken by the troops of the Catholic League in 1624, and was destroyed by the French in 1689. The story of the 400 citizens of Pforzheim who sacrificed themselves for their prince after the battle of Wimpfen in May 1622 has been relegated by modern historical research to the domain of legend.

See Coste, Die 300 Pforzheimer (1879); Brombacher, Der Tod der 300 Pforzheimer (Pforzheim, 1886); Stolz, Geschichte der Stadt Pforzheim (Pforzheim, 1901).

PHAEDO, Greek philosopher, founder of the Elian school, was a native of Elis, born in the last years of the 5th century B.C. In the war of 401-400 between Sparta and Elis he was taken prisoner and became a slave in Athens, where his beauty brought him notoriety. He became a pupil of Socrates, who conceived a warm affection for him. It appears that he was intimate with Cebes and Plato, and he gave his name to one of Plato's dialogues. Aenesidæus relates, however, that he resolutely declined responsibility for any of the views with which Plato credits him, and that the relations between him and Plato were the reverse of friendly. Aeschines also wrote a dialogue called Phædo. Shortly after the death of Socrates Phædo returned to Elis, where his disciples included Archipusus, Moschus and Pleistanes, who succeeded him. Subsequently Menedemus and Asclepiades transferred the school to Eretria, where it was known as the Eretrian school and is frequently identified (e.g. by Cicero) with the Megarian. The doctrines of Phædo are not known, nor is it possible to infer them from the Platonic dialogue. His writings, none of which are preserved, were in the form of dialogues. As to their authenticity nothing is known, in spite of an attempt at selection by Panaetius (Diog. Laërt. ii. 64), who maintains that theDialogues and the Simon are genuine. Seneca has preserved one of his dicta (Epist. 94. 41), namely that one method of acquiring virtue is to frequent the society of good men.

See Wilamowitz, Hermes, xiv. 189 seq.

PHAEDRA, in Greek legend, daughter of Minos and Pasiphae. With her sister Ariadne she was carried off by Theseus to Athens, and became his wife. On the way to Eleusis she met Hippolytus, son of Theseus by a former wife (Hippolyte, queen of the Amazon, or her sister Antiope), and fell in love with him. Finding her advances rejected, she hung herself, leaving behind a letter in which she accused Hippolytus of having made dishonourable proposals. The same story, in the main, is told of Bellerophon and Antea. It formed the subject of tragedies by Sophocles, Euripides (two, one of which is extant), Seneca and Racine.

PHAEDRUS, Roman fabulist, was by birth a Macedonian and lived in the reigns of Augustus, Tiberius, Gaius and Claudius. According to his own statement (prologue), he was born on the Pterian Mountain, but he seems to have been brought at an early age to Italy, for he mentions that he read a verse of Ennius as a boy at school. According to the heading of the chief MS. he was a slave and was freed by Augustus. He incurred the wrath of Sejanus, the powerful minister of Tiberius, by some supposed allusions in his fables, and was brought to trial and punished. We learn this from the prologue to the third book, which is dedicated to Eutychus, who has been identified with the famous charioteer and favourite of Gaius. The fourth book is dedicated to Particulio, who seems to have been dabbled in literature. The dates of their publication are unknown, but Suetonius writing between A.D. 103 and 104 (Consol. ad Polyb. 27), knows nothing of Phaedrus, and it is probable that he had published nothing then. His work shows little or no originality; he simply versified in iambic trimeters the fables current in his day under the name of "Aesop," interspersing them with anecdotes drawn from daily life, history and mythology. He tells his fable and draws the moral with businesslike directness and simplicity; his language is terse and clear, but thoroughly prosaic, though it occasionally attains a dignity bordering on eloquence. His Latin is correct, and, except for an excessive and peculiar use of abstract words, shows hardly anything that might not have been written in the Augustan age. From a literary point of view Phædrus is inferior to Bambrius, and to his own imitator, La Fontaine; he lacks the quiet picturesque ness and pathos of the former, and the exuberant vivacity and humour of the latter. Though he frequently refers to the envy and detraction which pursued him, Phaedrus seems to have attracted little attention in antiquity. He is mentioned by Martian (iii. 20, 5), who imitated some of his verses, and by Avianus. Prudentius must have read him, for he imitates one of his lines (Prud. Cat. vii. 115; cf. Phaedrus, iii. 27).

The first edition of the five books of Phædrus was published by Pithou at Troyes in 1596 from a manuscript now in the possession of the marquis of Rosanbo. In the beginning of the 18th century there was discovered at Parma a MS. of Perotti (1450-1480), archivist of Piacenza, containing many of the fables of Phædrus of which the majority are new, and some thirty were new. These new fables were first published at Naples by Casisato in 1608, and afterwards (much more correctly) by Jannell in 1608. Both editions were superseded by the discovery of Pforzheimer (1886), who published a MS. of Angelo Mai in 1831. For some time the authenticity of these new fables was disputed, but they are now generally accepted, and with justice, as genuine fables of Phædrus. They do not form a sixth book, for we know from Avianus that Phædrus wrote five books only, but it is impossible to assign them to their original places in the five books. They are usually printed as an appendix.

In the middle ages Phædrus exercised a considerable influence through the prose versions of his fables which were current, though his works were not widely read. His name was forgotten in the Latin versions the oldest existing seems to be that known as the "Anonymus Nilanti," so called because first edited by Nilant at Leiden in 1709 from a MS. of the 13th century. It approaches the text of Phædrus so closely that it must have been derived from it. Of the sixty-seven fables which it contains thirty are derived from lost fables of Phædrus. But the largest and most influential of the prose versions of Phædrus is that which bears the name of "Romulis." It contains eighty-eight of his fables, and seems to have been based on a still earlier prose version, which, under the name of "Aesop," and addressed to one Rufus, may have been made in the Carolingian period or even earlier. About this "Romulis" nothing is known. The collection of fables in the Weissenburg (now Wolfenbüttel) MS. is based on the same version as "Romulis." These three prose versions contain in all one hundred distinct fables, of which fifty-six are derived from the existing and the remaining forty-four presumably from lost fables of Phædrus. Some scholars, as Burman, Dümler and J. Müller, have tried to restore these lost fables by versifying the prose versions.

The collection bearing the name of "Romulis" became the source from which, during the second half of the middle ages, almost all the collections of Latin prose fables were drawn. The 12th-century version of the first three books of "Romulis," in elegiac verse enjoyed a wide popularity, even into the Renaissance. Its author (generally referred to since the edition of Nèvvet in 1610 as the "Anonymus Neveleti"") was long unknown, but has been identified with the editor of the Weissenburg MS. of "Romulis" in London, chaplain to Henry II. and afterwards archbishop of Palermo.

Another version of "Romulis" in Latin elegies was made by Alexander of Florence, both of which was published in 1558. Amongst the collections partly derived from "Romulis" the most famous is probably that in French verse by Marie de France. About 1200 a collection of fables in Latin prose, based partly on "Romulis," was made by the Cistercian monk Odo of Sherrington; they have a strong clerical colour. In 1376 a French version of Miroir wrote a poetical version of "Romulis" in Low German.

Since Pithou's edition in 1596 Phædrus has been often edited and translated; amongst the editions may be mentioned those of Burmann (1640 and 1677), Burnet (1726), Schwalbe (1806), Berger de Vivrey (1830), Orelli (1832), Eysenhard (1867), L. Müller (1876), R. H. (1885), and above all that of L. Havet (Paris, 1895). For the
PHAER—PHAGOCYTOSIS

medieval versions of Phaethus and their derivatives see L. Roth, in Philologus, i. 523 seq.; E. Grosse, in Jahrb. f. class. Philol., cv. (1872); and especially the learned work of Hervieux, Les Fabulistes latins depuis le sicle d'Auguste jusqu'à la fin du moyen âge (Paris, 1884). It gives the Latin texts of all the medieval Latin imitations (direct and indirect) of Phaethus, some of them being published for the first time.

PHAER (or PHAYER), THOMAS (1510-1560), English translator of Virgil, was educated at Oxford and at Lincoln's Inn. He published in 1533 Natura brucium, and in 1543 Newe Boke of Presidentes. He published contributions to the title-page of the translation of the Aeneid that he was "solicitor to the king and queen's majesties, attending their honourable council in the marches of Wales." He settled at Kilgarran in Pembrokeshire, and combined the study of medicine with his legal practice. He wrote several medical works, and was admitted M.D. of Oxford in 1530. He contributed to Sackville's Mirror for Magistrates, "Howe Owen Glendower, being seduced by false prophecies, took upon him to be Prince of Wales." In 1558 appeared The Seven First Books of the Eneidus of Virgili translated into English Meter. He had published two more books in April 1560 and had begun the tenth but had died in the autumn of that year leaving his task incomplete. The translation was finished by Thomas Twyne in 1584. Phayer's translation, which was in rhyme fourteen-syllabled lines, was greatly admired by his contemporaries, and he deserves credit as the first to attempt a complete version, the earlier renderings of Surrey and Gawain Douglas being fragmentary although of greater poetic value.

PHAETHON (Gr. φαέθων, shining, radiant), in Greek mythology, the son of Helios the sun-god, and the nymph Clymene. He persuaded his father to let him drive the chariot of the sun across the sky, but he lost control of the horses, and driving too near the earth scorched it. To save the world from utter destruction Zeus killed Phaethon with a thunderbolt. He fell to earth at the mouth of the Eridanus, a river of northern Europe (identified in later times with the Po), on the banks of which his weeping sisters, the Heliades, were transformed into poplars and their tears into amber. This point of the legend is the subject of a drama of the same name by Euripides, of some of which fragments remain, and of a lost tragedy of Aeschylus (Heliades); the story is most fully told in the Metamorphoses of Ovid (i. 750-ii. 366 and Nonnus, Dionysiaca, xxxviii). Phaethon has been identified with the sun himself and with the morning star (Phosphorus). In the former case the legend is supposed to represent the sun sinking in the west in a blaze of light. His identification with the morning star is supported by Hyginus (Astron. ii. 42), where it is stated that the morning (and evening) star was the son of Cephalus and Eos (the father and mother of Phaethon according to Hesiod, Theog. 984-986). The fall of Phaethon is a favourite subject, especially on sarcophagus reliefs, as indicating the transitoriness of human life.

PHAGOCYTOSIS (Gr. φάγειν, to eat, devour, and δόρος, cell). Many cells of the body possess the property of engulfing particles, a character to be associated with their power of performing amoeboid movement. This property is termed phagocytosis. Primarily this phagocytic power was simply the means by which the cell took within its cell body food particles which were ultimately digested and assimilated. In the higher organisms, however, this property has been developed for different purposes, and in pathology at the present day a meaning wider than that above given is often included in the term. The particle having been taken into the cell, one of three things may happen. (1) The particle may consist of digestible material, in which case the cell secretes a digestive fluid, a food vacuole is formed, the particle is gradually dissolved by the secretion and the products assimilated into the cell substance. (2) The particle may be indigestible, in which case it is retained within the cell body for a time and ultimately discharged. The particle engulfed may comprise almost any material, but if it is to serve as a food it must be of animal or vegetable origin. At the time of ingestion it may be dead or living. In the case in which it is living the organism is first killed and then digested, or (3) the organism may prove resistant, in which case it may multiply and finally destroy the cell, when a number of organisms are set free. This is one of the means by which, in the higher organisms, a local infection may become distributed through the organism. The digestion effected within a cell is fermentative in character. Thus a proteolytic ferment has been prepared from the bodies of amoeba—the ferment possessing fairly active properties both in acid, neutral or alkaline media, but especially in the latter.

In studying the processes of phagocytosis generally much information may be gained as to its general characters by the study of the processes of intracellular digestion in the simpler Invertebrates, a study largely extended by Metchnikoff and his co-workers in the elaboration of Metchnikoff's view of the nature of immunity. Thus, to take an instance from the sponges. Food substances, in the form of minute organisms, which have penetrated the pores of the sponge are seized by the ciliated or amoeboid cells lining those spaces, and are then killed and digested. In this case also the process of digestion is proved to be fermentative. It is readily understandable that we should find such cells on the external surface of an organism or on the surface lining the alimentary tract, particularly in the latter position. But in addition there are many cells within the body in which phagocytic power is retained and markedly developed. Such cells may be fixed or wandering cells. They are employed for removing foreign material or debris which may occur within a tissue. For instance, as the result of an injury, inflammatory process, &c., cells and other structures of a tissue may be destroyed. One of the processes of repair consists in the removal of the resulting debris, which is effected by phagocytes. A similar process is seen with red blood corpuscles which may have escaped into a tissue through rupture of capillaries. Foreign particles incidently gaining admission to a tissue are in many cases removed in a similar manner, e.g., soot particles which have passed through the respiratory surface are then largely removed by phagocytes and carried to the bronchial lymphatic glands. Very commonly living organisms effect an entrance through wound surfaces, the alimentary surface, &c., and one of the processes employed for their destruction and removal is that of phagocytosis.

As an illustration of the removal of foreign red blood corpuscles we may take the experiments of Metchnikoff in which a small drop of defibrinated blood of the goose was injected under the skin of a snail. The corpuscles quickly spread through the haemolymph of the snail, which by itself, however, effects no change in them. At the end of several hours examination shows that the leucocytes of the snail have engulfed a large number of the red corpuscles. The following day intact corpuscles will be found in the haemolymph, but the major number have already been devoured by the leucocytes. When taken up by a phagocyte the red corpuscle becomes round and its wall permeable. A vacuole is formed around the corpuscle, in which dissolved haemoglobin can be seen; a part of this haemoglobin also passes into the nucleus of the red corpuscle, proving that it too has been profoundly altered. Many of the nuclei are discharged. After some time the only parts of the corpuscle remaining are pieces of the nucleus and the peripheral layer of the corpuscle. Frequently the phagocytes, after having devoured one or several red corpuscles, themselves become a prey to their fellows. Analogous changes are observed in the tissues of a mammal when blood which has been extravasated is being removed, e.g., after a bruise. The first effect of the haemorrhage is an exudative inflammation, during which leucocytes arrive in large numbers and engulf the corpuscles. In the process of digestion which follows the haemoglobin is altered and new pigment formed from it. In mammals this pigment is dark red or brownish, in the pigeon it is green. Finally the corpuscles are completely digested. Analogous phenomena may be observed
in connexion with the removal of cell débris resulting from any injury. Numbers of phagocytes may be found at work in this direction, for instance in the pus formed within an aseptic abscess. Hence we may regard the phagocytes as acting as the scavengers of the tissues.

In the instances we have been dealing with the phagocytes are chiefly of the class of wandering cells and are brought to the seat of their activity by the blood. In examining any tissue where the process is going on it is seen that the phagocytes have accumulated there in large numbers. They have been attracted to the damaged area. The mechanism which effects this attraction is a chemical one—chemotaxis. At the seat of the change chemical substances are produced which act upon the phagocytes, causing them to migrate towards the source—positive chemotaxis. Apparently the material dissolving from cell débris can in this manner. Thus if a capillary tube filled with a tissue extract be inserted under the skin of an animal, within a short time phagocytes will be found to be surrounded with numbers of leucocytes, which may also have encroached into the tube itself. As in other instances of chemotaxis the same chemical stimulus in a higher concentration may repel the cells—negative chemotaxis. Instances of this are especially frequent in relation to micro-organisms and phagocytes, to which we may now turn.

That phagocytes can paralyse, kill and digest many micro-organisms is the main fact in Metchnikoff's theory of the nature of immunity. The reaction may be readily studied by injecting a small quantity of a fluid culture of some mildly pathogenic organism into the peritoneal cavity of an animal, and in the course of an hour or so examining a smear from the surface of the omentum, when an abundance of phagocytes enclosing the organism in different stages of digestion will be found. Or we may adopt Leishman's method, in which a few drops of human blood are diluted with saline solution and centrifuged. The layer of white corpuscles is pipetted off, suspended in serum, and a mixture of horse serum and leucocytes of a patient's is used. The preparation is then incubated at 37°C for a quarter of an hour. Upon examining a drop of this mixture a number of bacteria are found within the phagocytes. Thus this attack and destruction of bacteria by phagocytes may take place within the body or by cells removed from the body. Whether or not a phagocyte can engulf bacteria is dependent upon a number of factors—partly specific properties of the phagocyte, partly factors varying with the constitution of the body serum. Thus Wright and Douglas, employing Leishman's method, have proved that leucocytes do not take up bacteria freely unless the serum in which they are suspended contain opsonins. They found, for example, that leucocytes taken from a patient suffering from a pyococcal infection if suspended in normal human serum take up the cocci abundantly, whereas if the same leucocytes are suspended under similar conditions in the patient's own serum the reaction may be almost absent. Further, leucocytes taken from a normal individual and suspended in the patient's serum are practically inactive, while the same phagocytes in normal serum are very active. Exactly how the substance in the serum acts is undecided, but it has been proved that there are in the serum substances which become fixed to bacteria and which render them an easier prey to the phagocytes. This specific opsonin is used up when the bacteria are added to the serum, so that if the bacteria are subsequently removed the serum is no longer active. There is evidence too that there is a multiplicity of opsonins. As the origin of the opsonins we have no certain evidence. It is suggested that they are a secretion from the leucocytes themselves and that it is an evidence of another and preliminary mode of attack possessed by the leucocyte, viz. the discharge of a secretion from the cell which is to damage or paralyse the bacterium and thus enable the phagocyte to engulf it.

The mechanism of destruction of a bacterium once it has been taken up by a phagocyte is probably, just as in the instance of dead cellular material, one of intracellular digestion. The bacterium before being engulfed is probably inert in most instances, though it may yet prove too strong for the phagocyte. The next stage we can trace is the formation of a vacuole around the organism, or, if the latter be large, around a part of the organism, and the part thus surrounded quickly shows signs of destruction. For instance, its staining reactions become weaker. When a part only of the organism is surrounded by a vacuole the part thus surrounded soon ceases to stain, while the remaining part stains normally, and we thus have a marked contrast evidencing the two stages.

In the next place we must ask which are the cells possessing phagocytic powers? Leaving apart the cells lining the alimentary tract (because we know practically nothing of their power in this respect) a number of free cells possess amoeboid properties as well as also a number of fixed cells. These latter are attached to certain spots of a tissue, but are capable of throwing out processes which can seize upon particles of foreign matter or even upon certain elements of the same organism. Of this category Metchnikoff distinguishes the nerve cells, the large cells of the spleen pulp and of lymph glands, certain endothelial cells, the neuroglia cells, and perhaps certain cells of connective tissues. All these elements can under certain conditions act as phagocytes, and with the exception of the nerve cells all are of mesoblastic origin. Those of greater importance on account of their greater activity in this respect are the large splenic and lymph cells, the neuroglia cells and certain endothelial cells. With regard to the wandering cells Metchnikoff considers that some are certainly non-phagocytic, for instance the lymphocytes. According to Metchnikoff it is only when these cells become older and have developed a nucleus rich in chromat in and an abundant cell body that these cells develop phagocytic properties. This is the large hyaline leucocyte. The polymorphonuclear and the eosinophil leucocyte are both phagocytes. Metchnikoff therefore divides the phagocytes into two classes—the microphages, comprising the polymorphonuclear and the eosinophil cell, and the macrophages, containing the large hyaline cell, the cell of the splenic pulp, the endothelial cell and the neuroglia cell. From further observation of these cells he concludes that the microphages are chiefly concerned in opposing the micro-organisms of acute infections, whereas the macrophages are chiefly concerned in combating chronic infections. It is the macrophage also which is concerned in removing cell débris, e.g. red corpuscles from a haemorrhage or the red corpuscles of another animal which may have been introduced experimentally.

Metchnikoff and his co-workers have shown that the two principal groups of leucocytes are generally spread throughout the vertebrates. Thus instances of each kind are found even in the lamprey, though here their staining properties are feeble; also cells which show but small differences from the analogous cells of mammals are found in the alligator. (T. G. Br.)

**PHALANGER**

is a book-name applied to the more typical representatives of the group of diprotodont marsupial mammals, including the cuscuses of the Moluccas and Celebes, and the so-called opossums of Australia, and thus collectively the whole family Phalangeridae. (See Marsupialia.)

Phalangers generally are small or medium-sized woolly-coated marsupials, with long, powerful, and often prehensile tails, large claws, and opposable nailless first hind toes. They seem in the day to be dull and sleepy, but are alert at night. They live mostly upon fruits, leaves and blossoms, although a few feed habitually upon insects, and all relish, in confinement, an occasional bird or other small animal. Several possess flying-membranes stretched between their fore and hind limbs, by the help of which they can make long and sustained leaps through the air, like flying-squirrels; but the possession of these flying-membranes does not seem to be any indication of special affinity, the characters of the skull and teeth sharply dividing the flying forms and uniting them with other species of the non-flying groups. The skull (see fig. r) is, as a rule, broad and flattened, with the posterior part swollen out laterally owing to the numerous air-cells situated in the substance of the squamosal bones. The dental formula is very variable, especially as regards the premolars, of which some at least in each genus are reduced to functionless rudiments, and may even vary in number on the two sides of the jaw of the same individual. The incisors are
includes at least half a score of species. The dentition is generally i. 3, c. 3, p. 1, m. 4, but one upper incisor and the canine may be wanting. The crowns of the molars show a crescentic structure, but they are said to retain the three primitive cusps, which are fused in the other genera. The prehensile tail has its tip naked for a short distance, and the whole of the terminal third and the under surface of the remainder short-haired, the tip being generally white. The hair is thick and woolly, and generally yellowish-green in colour. These phalangers are the ring-tailed oppossums of the Australians. From this genus is apparently derived the tagan flying-squirrel, or flying-phalanger (Petauris robustus), which ranges from Queensland to Victoria, and is the largest of the flying group. Its dentition is essentially similar to that of Pseudochirus, although there is one pair less of cheek-teeth, and the bushy tail is naked and prehensile at the tip. Reverting to the non-flying species, we have Gymnoblotetes leadbeateri, a small animal from Victoria representing a genus by itself, with the same dental formula as Pseudochirus, but cheek-teeth of a different type, the ears naked (instead of hairy) behind, glands on the chest and between the ears, and the tail long and even bushy to the tip. From this are evidently derived the flying-phalangers—flying-squirrels—of the genus Petaurus, which differ merely in the possession of a parachute, and are represented by several species, ranging from Australia to New Guinea. Of the yellow-bellied species, P. australis, the habits are described by J. Gould as follows: "This animal is common in all the bushes of New South Wales, particularly those which grow along the coast of Port Philip to Moreton Bay. In these vast foresta trees of one kind or another are perpetually flowering, and thus afford a never-failing supply of the blossoms upon which it feeds; the flowers of the various kinds of gums, some of which are of great magnitude, are the principal favourites. Like the rest of the genus, it is nocturnal in its habits, dwelling in holes and in the spouts of the larger branches during the day, and displaying the greatest activity at night, while running over the small leafy undergrowth and every even extremity, in search of insects and the honey of the newly opened blossoms. Its structure being ill adapted for terrestrial habits, it seldom descends to the ground except for the purpose of passing to a tree too distant to be attained by jumping, and when it does so it goes with the greatest difficulty. The tops of the trees are traversed by this animal with so much ease as the most level ground is by such as are destined for terra firma. If chased or forced to flight it ascends to the highest branch and performs the most enormous leaps, sweeping from tree to tree with wonderful address; a slight elevation gives its body an impetus which with the expansion of its membrane enables it to pass to a considerable distance, always ascending a little at the extremity of the leap; by this ascent the animal is prevented from receiving the shock which it would otherwise sustain."

A second species, P. sciuereus, in some ways one of the most beautiful of all mammals, is shown in fig. 2.

A precisely similar relationship exists between the tiny feather-tailed phalanger, Dystochoerus peninsulatus, of New Guinea, and the equally minute pigmy flying-phalanger or flying-mouse, Acroctes pygmaeus, of Queensland, New South Wales and Victoria; both being characterized by the hairs of the tail forming a vane on each side, as well as by tufts of long hairs at the base of the thinly-

like form, large, thin, and nearly naked ears, without tufts inside or at the base, sharp and rudimentary front claws and long sharp hind ones, and mouse-like tail, which is furry at the base, then scales and naked and prehensile at the tip. There may be either six or seven pairs of cheek-teeth, of which the hinder carry four small smooth cusps, and the first upper incisor is much longer than the other two. The striped phalangers (Dactylolagus) are larger animals of the approximate size of a squirrel, readily recognized by the longitudinal yellow and black striping of the fur, and the slender and elongated fourth front toe. The typical D. tririgrata is common to north Australia and New Guinea, but D. papua, which has the fourth toe still more elongated, is exclusively Papuan. They have seven pairs of cheek-teeth, of which the four last are oblong and four-cusped; and the first lower incisor is longer than in any other phalanger. They apparently feed on both leaves and grubs, probably extracting the latter from crannies with the elongated toe. The tail is more or less bare on the under side of the tip.

The last group of the sub-family is represented firstly by the cuscuses, or cuscus (Phalanger), which are arboreal animals of the approximate size of cats, and range from the Solomon Islands through New Guinea and the Moluccas to Celebes, being, in fact, the only Old World marsupials found westwards of New Guinea. Externally they are characterized by their thick woolly fur, short or even naked ears, which are hairy outside, and sori on the hindpaws well, by the naked and striated soles of the feet, and the long and markedly prehensile tail, of which the basal half is furry like the body, and the terminal tail entirely naked. The number of cheek-teeth varies, owing to the frequent absence of some of the front ones, but there are generally seven pairs, of which the last four carry crescents internally and cusps externally. About ten species are known, of the grey cuscus (P. orientalis) of Ambonya and Timor was discovered about 300 years ago, and was thus the first known Old World marsupial. In the spotted cuscus (P. maculatus) the males are marked with orange and white, while the females are uniformly greyish. Cuscuses are sleepy animals, feeding mainly on leaves, but also devouring birds and small mammals.

Nearly allied to the cuscuses are the typical Australian phalangers, or opossums, forming the genus Trichosurus. They differ from the cuscuses, among other features, by the thick and non-tapering tail being covered with bushy hair up to the extreme tip, which is naked, as is a narrow line along the middle of the terminal third
PHALANX—PHALTAN

(or rather more) of the lower surface, by the presence of a gland on the chest, and by the soles of the hind feet being hairy. In the skull the upper canine is separated from the outermost incisor, instead of close to it as in the canines (fig. 1). The best-known species is the brush-tailed phalanger, or "red-necked phalanger" (T. vulpecula), of Australia, an animal of the size of a small fox, represented in Tasmania by the brown phalanger (T. vulpecula fuliginosus). The short-eared phalanger (T. canina) represents the group of "eared phalangers" (q.v.) and appears to be wholly arboreal and mainly nocturnal in its habits; it is these which form the chief game in "opossum-shooting" among the gum-trees by night.

The long-nosed phalanger is referred to under Marsupialia.

R. L."

PHALANX (Gr. φαλάνξ, of unknown origin), the name, in Greek history of the arrangement of heavy-armed infantry in a single close mass of spearmen (see Army: History). In anatomy, the Latin plural phalanges is the term applied to the bones of the fingers and toe, and in botany a group of united stamen clusters. The term "phalanx" was adopted by F. C. M. Fourier (q.v.) as the name of the socialistic community living in a "phalangistery.

PHALARIS, tyrant of Acragas (Agrigentum) in Sicily, c. 570–554 B.C. He was entrusted with the building of the temple of Zeus Ataturbus in the citadel, and took advantage of his position to make himself despot (Aristotle, Politics, v. 10). Under his rule Agrigentum seems to have attained considerable prosperity. He supplied the city with water, adorned it with fine buildings, and strengthened it with walls. On the northern coast of the island the people of Himera elected him general with absolute power, in spite of the warnings of the poet Stesichorus (Aristotle, Rhetoric, ii. 20). According to Suidas he succeeded in making himself master of the whole of the island. He was at last thrown over in a general rising headed by Telemachus, the ancestor of Theron (tyrant c. 458–472), and burned in his brazen bull.

After ages have held up Phalaris to infamy for his excessive cruelty ("Phalaris") but his brazen bull, invented, it is said, by Perillus of Athens, the tyrant's victims were shut up and, a fire being kindled beneath, were roasted alive, while their shrieks represented the bellowing of the bull. Perillus himself is said to have been the first victim. There is hardly room to doubt that we have here a tradition of human sacrifice in connexion with the worship of the Phoenician Baal (Zeus Ataturbus) such as prevailed at Rhodes; when misfortune threatened Rhodes the brazen bulls in his temple bellowed. The Rhodian scholars, however, ascribed the worship of the bull to the Phoenicians, and the story, which seems to have been jointed with the Cretans, and from Creta it passed to Agrigentum. Human sacrifices to Baal were common, and, though in Phoenicia proper there is no proof that the victims were burned alive, the Carthaginians are said to have burned their victims alive. It is recorded that Phalaris held a brazen man who pressed people to his glowing breasts points to similar rites in Crete, where the child-devouring Minotaur was worshiped (possibly to be connected with Baal and the favourable sacrifice to him of children.

The story of the bull cannot be dismissed as pure invention. Pindar (Pythia, i. 185), who lived less than a century afterwards, expressly associates this instrument of terror with the Phalaris. There was certainly a brazen bull at Agrigentum, which was carried off by the Carthaginians to Carthage, whence it was again taken by Scipio and restored to Agrigentum (late 2nd cent. B.C.). It was certainly a naturally humane man and a patron of philosophy and literature. He is so described in the declarations ascribed to Lucian, and in the letters which bear his own name. Platarch, too, though he takes the idea from Plutarch, mentions the fable as one of the observations of Suidas in his Dictionary (1883). From the mention in the letters of Phalaris the name of justice and a hatred of crime. Phalaris may thus have been one of those who combine justice and even humanity with religious fanaticism (Suidas, τεκ. Diod. Sic. xxii. 25; Polybius vii. 7. xii. 25; Cicero, De Officiis, ii. 7. iii. 6).

The letters bearing the name of Phalaris (148 in number) are now chiefly remembered for the crushing exposure they received at the hands of Richard Bentley in his controversy with Bishop Ussher. Charles Boyle, who had published an edition of them in 1695. The first edition of Bentley's Dissertation on Phalaris appeared in 1697, and the second edition, repeating the answer which Boyle published in the first edition, appeared in 1699. From the imitation of certain towns (Phintia, Alasa, and Tauromenium) which did not exist in the time of Phalaris, from the imitations of authors (Herodotus, Democritus, Euripides, Callimachus) who wrote long after he was dead, from the reference to tragedies, though tragedies were in yet invented in the lifetime of Phalaris, from the dialect, which is not

Dorian but Attic, nay, New or Late Attic, as well as from absurdities in the matter, and the entire absence of any reference to them by any writer before Stobaeus (c. A.D. 500), Bentley sufficiently proved that the letters were written by a sophist or rhetorician (possibly a Brazen Beast) of the school of Aristides, who died 200 years after the death of Phalaris. Suidas admired the letters, which he thought genuine, and in modern times, before their exposure by Bentley, they were thought highly of by some (e.g. Sir William Temple in his Essay on Epicureanism, 1699, and perhaps other, as Politianus and Erasmus), perceived that they were not by Phalaris. The latest edition of the Epistles is by R. Hercher, in Epistolographia graeci (1853), and of Bentley's Dissertation by W. Wagner (with introduction and notes, 1853); see especially R. C. Jebb, Life of Bentley (1882).

PHALLICISM, or PHALLISM (from Gr. φαλλος), an anthropological term applied to that form of nature worship in which adoration is paid to the generative function symbolized by the phallus, the male organ. It is common among primitive peoples, especially in the East, and has been prominent also among more advanced peoples, e.g. the Phoenicians and the Greeks. In its most elementary form it is associated with frankly orgiastic rites. This aspect remains in more advanced forms, but gradually it tends to give place to the joyous recognition of the principle of natural reproduction. In Greece for example, where phallism was the essence of the Dionysiac worship and a phallic revel was the origin of comedy (see Hermes), the purely material and the symbolical aspects no doubt existed side by side; the Orphic mysteries had to the intellectual Greeks a significance wholly different from that which they had to the common people. Phallic worship is especially interesting as a form of sympathetic magic: observing the fertilizing effect of sun and rain, the savage sought to promote the growth of vegetation in the spring by means of symbolic sexual indulgence. Such were the rites which shocked Jewish writers in connexion with the worship of Baal and Astarte (see Baal, and cf. Astartes, Istar). The same principle is at work in the worship of Astarte, whose chief deity, the Great Mother of the Gods (q.v.), in the personification of the earth's fertility: similarly in India worship is paid to divine mothers. Generally it should be observed that phallic worship is not specially or perhaps primarily paid to male deities, though commonly the more important deity is accompanied by a companion of the other sex, or is itself androgynous, the two symbols being found together.

In the Dionysiac rites the emblem was carried at the head of the procession and was immediately followed by a body of men dressed as women (the ithyphalli). In Rome the phallic was the most common amulet worn by children to avert the evil eye: the Latin word was fascinum (cf. Pliny, Nat. Hist. xix. 50, satyrica signa; Varro, Ling. Lat. vii. 97, ed. Müller). Pollux says that such emblems were placed by smiths before their forges. Before the temple of Aphrodite at Hierapolis (q.v.) there were two huge phalli (180 ft. high), and other similar objects existed in all parts of the ancient world both in statuary and in painting. Among the Hindus (see Hinduesism) the phallus is called linga or lingam, with the female counterpart called yoni; the linga symbolizes the generative power of Siva, and is a charm against sterility. The rites classified together as Sakti pujā represent the adoration of the female principle. In Mexico, Central America, Peru and other parts of America phallic emblems are found. The tendency, however, to identify all obelisk-like stones and tree-trunks, together with rites like circumcision, as remains of phallic worship, has met with much criticism (e.g. Robertson Smith, Religion of the Semites, 2nd ed., pp. 456 sqq.).

For authorities see works quoted under Religion: §§ A and B

PHALTAN, a native state of India, in the central division of Bombay, ranking as one of the Satara jagirs. Area, 307 sq. m.; pop. (1901), 84,730, showing a decrease of 11% in the decade. The estimated revenue is £1,500, and the tribute £640. The chief, whose title is nimbalkar, is a Mahatta, tracing his descent to a grante from a Delhi emperor in the 14th century. The town of Phaltan is 37 m. north-east of Satara; pop. (1901), 9572.
PHANARIOTES—PHARISEES

PHANARIOTES, a name derived from Phanar, the chief Greek quarter at Stambool, where the eccenical patriarchate is situated, and applied to those members of families resident in the Phanar quarter who between the years 1711 and 1821 were appointed hospodars of the Danubian principalities; that period of Mold-Wallachian history is also usually termed the Phanariote epoch. It is not to be understood as marking the introduction into the principalities of the Greek element, which had already established itself firmly in both provinces, to both of which Greek princes had been appointed before the 18th century. But whereas the Greek families of earlier introduction gradually became merged in their country of adoption, the later immigrants retained their separate nationality and grew to be powerful agents for furthering the spread of Graecism in the principalities. The person raised to the princely dignity was usually the chief dietarch of the Sublime Porte, and was consequently well versed in contemporary politics and the statecraft of the Ottoman government. The new prince, who was compelled to purchase his elevation with a heavy bribe, proceeded to the country which he was selected to govern, and of the language of which he was in nearly every case totally ignorant, accompanied by a horde of needy hangers-on; he and his acolytes counted on recouping themselves in as short a time as possible for their initial outlay and in laying by a sufficiency to live on after the termination of the prince's brief authority. It was the interest of the Porte to change the princes as often as possible, as the accession donation thus became due more frequently. When, owing to the numerous cases of treachery among the princes, the choice became limited to a few families the plan was hit upon of frequently shifting the prince from one province to the other: the prince of Wallachia, the richer of the two principalities, was always ready to pay a handsome douceur to avert his transfer to Yass; the prince of Moldavia was equally ready to bribe his supporters at Constantinople to secure his appointment to Wallachia. To raise funds to satisfy the rapacity of the Porte the princes became past masters in the art of spoliation, and the inhabitants, liable to every species of tax which the ingenuity of their Greek rulers could devise, were reduced to the last stage of destitution. The active part taken by the Greek princes in the revolt of 1820-21 induced the Porte to revert to the appointment of native princes.

PHANIAS, of Eresus in Lesbos, Greek philosopher, important as an immediate follower of and commentator on Aristotle, came to Athens about 332 B.C. and joined his compatriot Theophrastus, in the Peripatetic school. He wrote works entitled Analytica, Categoriae and De interpretatione, which were either paraphrases or critical commentaries, and seem to have added little to Aristotle's own writings. Alexander of Aphrodisias refers to a work πρὸς Διόδωρον, and Athenaeus quotes from another treatise, Against the Sophists. Outside philosophy, he and Theophrastus carried on the physical investigations of Aristotle; Athenaeus frequently quotes from a work on botany which manifests great care in definitions and accuracy of observation. From Plutarch (Life of Themistocles) we learn that he was regarded as an historian of importance. The chief of his historical works is the Prytaneis Eresii, which was either a history of his native place or a general history of Greece arranged according to the period of the Eresian magistracy. He wrote also of the Tyrants of Sicily and on tyranny in general. The value of these books is attested by the frequency with which they are quoted on questions of chronology (e.g. by Plutarch, Suidas, Athenaeus). To the history of Greek literature he contributed works on the poets and on the Socrates, both of which are quoted.

He must be distinguished from another Phanias, a Stoic philosopher, disciple of Posidonius, Diogenes Laërtius mentions a work of his wherein he compares Posidonius with Pametius in arguing from physical principles.

PHANOCLES, Greek elegiac poet, probably flourished about the time of Alexander the Great. His extant fragments show resemblances in style and language to Philetas, Callimachus and Hermesianax. He was the author of a poem on paederasty. A lengthy fragment in Stobaeus (Florilegium, 64) describes the love of Orpheus for the youthful Calais, son of Boreas and his subsequent death at the hands of the Thracian women. It is one of the best extant specimens of Greek elegiac poetry.

See N. Bach, Philetæa, Hermianæctis, et Phanoclis reliquiae (1829); L. Preller, Ausgewählte Aufsätze aus dem Gebiete der klassischen Alterthumswissenschaft (1864).

PHANTASMAGORIA, a name invented by a certain Philipstil in 1802 (from Gr. φαντασμα, phantasm, apparition; and ἀγώρι, assembly) for a show or exhibition of optical illusions produced by means of the projecting lantern (q.v.). The word has since been applied to any rapidly or strikingly changing scene, and especially to a disordered or fantastic scene or picture of the imagination.

PHARAOH (Par'oh), the Hebrewized title of the king of Egypt (g.n.), in Egyptian Per-o; Phorion in Herodotus represents the same. Its combination with the name of the king, as in Pharaon-Necho, Pharaoh-Hophra, is in accordance with contemporary native usage: the name of the earlier Pharaoh Shishak (Sheshonk) is rightly given without the title. In hieroglyphic a king bears several names preceded by distinctive titles. In the IVth Dynasty there might be four of the latter: (1) identifying him with the royal god Horus; the name is commonly written in a frame representing the façade of a building, perhaps a palace or tomb, on which the falcon stands. (2) connecting him with the vulture and uraeus goddesses, Nekhbi and Buto of the south and north. (3) a hawk on the symbol of gold, signifying the victorious Horus. (4) the old titles of the rulers of the separate kingdoms of Upper and Lower Egypt, to be read stti, "butcher" and byit, "beckeret." The personal name of the king followed (4), and was enclosed in a cartouche C apparently symbolizing the circuit of the sun which alone bounded the king's rule. Before the IVth Dynasty the cartouche was seldom found: the usual title is (1), (2) and (3) does not occur. In the IVth Dynasty the custom began of giving the king at his accession a special name connecting him with the sun: this was placed in the cartouche after (4), and a fifth title was added: (5) Si-re, "son of the Sun-god," to precede a cartouche containing the personal name. The king was briefly spoken of by his title stii (see 4), or hnm-fl, "his service," or IHy, "liege-lord." These titles were preserved in the sacred writing down to the latest age. An old term for the royal palace establishment and estate was Per-o, "the Great House," and this gradually became the personal designation of Pharaoh (cf. the Grand Porte), displacing all others in the popular language.

PHAR, a town of Tibet. It is supposed to be the highest and coldest town in the world, being 15,000 ft. above the sea. As it commands the road between the Chumbi Valley and Lhasa and also one of the chief passes into Bhutan, Phari is of considerable military importance, and is defended by a large fort or Jong, which was occupied by the British expedition of 1904. Phari Jong is supposed to have been built about 1500 a.d., and was enlarged or rebuilt in 1792, under Chinese advice, as a defense against the British. It has the appearance of a medieval castle, and seems to have been built in imitation of the European style.

PHARISEES, a sect of the Jews first mentioned by Josephus, in his account (Ant. xiii. 5, 9) of the reign of Jonathan, the brother and successor of Judah Maccabaeus. The name, which may be translated "Separatists," indicates their devotion to the ideal, enforced by Ezra and Nehemiah upon the reluctant Jews, of a nation separate from all other nations in virtue of its
PHARMACOLOGY
Yahweh (Neh. ix.). This
who were prepared to obey

peculiar relation to

ideal

nation

consisted of all
the Law of
Moses, irrespective of their natural descent. Consequently the
Pharisees, who seem to have been an order of religious teachers,
were concerned to make converts (proselytes), and some of their

piecemeal realization of the dreams of their supposed opponents,
which gain a vague glory from their being far off.

The gospels generally have left upon the minds of men an
impression unfavourable to the Pharisees. They contain denunciations attributed to our Lord and assigned with obvious
injustice in some cases
to the scribes of this sect. It is to be
remembered that the Pharisees were the only sect of the Jews
also concerned to insist upon the strict observance of the Law,
who survived in Christian times and that the Pharisees were
so far as it was compatible with the exigencies of ordinary life,
and to train disciples who should set"~a proper example to the never a homogeneous body possessed of a definite policy or body
of doctrine. Moreover it is clear that our Lord denounced not
mass of the people.
The ideal of separation descended from the Great Synagogue all the Pharisees but the hypocrites only, as did the rabbis
(Assembly) of the time of Ezra to the Synagogue of the Hasi- whose sayings are reported in the Talmud and other Jewish
daeans (Assidaeons), who allied themselves with Judas Macca- books. Again the third gospel in particular betrays relations
baeus when his followers decided to suspend the law of the between the Pharisees and Jesus very different from those of the
Sabbath, in order that the true Jews might preserve themselves common Christian view, which conjures up an impossible picture
from annihilation and survive to keep the Law as a whole. This of an absolute breach between the Prophet of Nazareth and
action of the Hasidaeans is clearly the practical outcome of the the whole corporation of the Pharisees as a result of a quarrel
with certain members of that dissident sect of independent
principle which Josephus describes in the language of philosophy
thinkers.
Gamaliel and his pupil St Paul Are better representaas the characteristic of the Pharisees

use, and most of the newer standard textbooks combine together the consideration of pharmacology and therapeutics. Pharmacology is also related to toxicology, as many remedial and other agents are more or less poisonous when given in large doses, but it does not include the detection, tests, and the other strictly medico-legal aspects of poisoning.

Pharmacology proper began as the result of the application of strictly experimental methods to physiology. The discovery (early in the 19th century) that plants owe their remedial and poisonous qualities to small quantities of definite active principles, such as alkaloids and neutral bodies, which can be extracted in a chemically pure condition, had also a very important effect on its development. We meet first with experiments made by investigators who perceived that observations on man and animals might lead to a better understanding of the action of drugs. In 1676 Wepfer and Conrad Brunner demonstrated on dogs the tetanising action of nux vomica, and similar rough experiments were repeated from time to time with other substances by later investigators. In 1755 Menghini published an elaborate study of the action of camphor on a great variety of different kinds of animals. Albert von Haller (b. 1708) sought to elucidate the action of remedies by observations on healthy men, and in 1767 William Alexander made experiments on himself with drugs, which were, however, brought to an abrupt termination by his nearly killing himself. In 1776 Daries, by observations on himself and on cats, established the mydriatic action of belladonna and other atropoanous plants. Hitherto no attempt had been made to determine what particular parts of the body were especially affected by drugs, but Fontana showed, in his great work (Florence, 1765) on the venom of the viper and on other poisons, that the general symptoms were brought about by an action on particular organs. He performed more than six thousand experiments, more than four thousand of which were on animals, and he determined the effects on the heart and other important structures. These analytical methods of research were well known to the second generation in Edinburgh and to his pupils, one of whom, William Alexander, wrote a thesis in 1790 entitled “De partibus corporis animalis quae viribus opii parent.” His methods were doubtless known also to the French physiologist Magendie, who improved upon them, and who in 1809 published a research on the Upas Tieté and other strychine-containing plants, in which he showed that their effects were due to an action on the spinal cord. The researches of his pupil, Claude Bernard, on curare, were equally exact and logical, and have served as the model for many subsequent investigations. In consequence, from the time of Magendie pharmacology may be said to have been put on a more exact basis. By the middle of the 19th century there were many workers on the subject, and the actions of such drugs as digitals, morphine, alcohol, and many others had been frequently and minutely investigated. About this time Buchheim, professor of materia medica in Dorpat from 1826 to 1874, founded the first pharmacological laboratory in modern Russia, and introduced a more rational classification of drugs than had hitherto been in use, arranging them in groups according to their pharmacological actions. In the herbals and older treatises on materia medica and therapeutics no explanation is usually offered of the action of medicines, and in such works as that of Cullen (1786) only a few of the more obvious actions are occasionally explained according to the current theories of physiology and pathology. In works such as Parreira’s Elements of Materia Medica and Therapeutics (1842), the physiological effects of medicines are usually described, but very briefly as compared with the materia medica. At the present day most textbooks dealing with medicinal agents and treatment devote a large part of their space to pharmacology, and a corresponding change has taken place in the teaching of the subject in universities and medical schools. Since Magendie’s time numerous papers dealing with pharmacological subjects have appeared in the Journal of Anatomy and Physiology, the Journal of Physiology, Virchow’s Archiv, and the principal medical periodicals of all countries. In 1873 the Archiv für experimentelle Pathologie und Pharmakologie first appeared, in 1895 the Archives Internationales de Pharmacodynamie, and in 1909 The Journal of Pharmacology and Therapeutics (published at Baltimore, U.S.A.), all of which are chiefly or entirely devoted to pharmacology.

The methods of research are essentially those employed by physiologists, the action of substances being studied in the usual way on bacteria, leukocytes, frogs, rabbits and other animals. Not only are the general symptoms investigated, but it is necessary to carry out experiments on the nerves, muscles, circulation, secretions, &c., so as to get a more exact knowledge of the reasons of the general action. It is true that many of these animals react somewhat differently to drugs, both as regards each other and as regards man, but for the most part the differences are quantitative rather than qualitative. After carrying out a series of observations on animals, the drug can be assigned to its special group, and a good idea can be obtained of its possible practical value or the reverse; hence there is a saving of time and an avoidance of the necessity of testing its effects on man. The action of a drug may be called direct when it acts on any part to which it is immediately applied, or which it may reach through the blood; and indirect when one organ is affected secondarily to another, as, for instance, in strychnine poisoning when the muscles are violently contracted as the result of the action of the alkaloid upon the spinal cord. In a few cases the action is merely physical, but most frequently it is chemical in its nature, and is exerted on the living cell, the activity of which is either stimulated or depressed. In some cases the substances actually enter into a chemical combination with the protoplasm, which may be temporary or (much less frequently) permanent; in other cases they seem simply to modify or disturb the usual chemical activity of the cells. Prolonged or excessive stimulation invariably leads to depression or paralysis, the tissues becoming fatigued, and from this condition they may recover or they may not. When we come to consider more in detail the results of these actions we find that the various secretions of the body, such as the sweat, gastric juice, bile, milk, urine, &c., may be increased or diminished; that the heart may have its muscular or nervous apparatus stimulated or depressed; that the nerve-centres in the brain, medulla and spinal cord may be rendered more sensitive or the reverse; and that the general metabolism of the body may be altered in various ways. In addition, the fluid constituents, such as the lymph and blood, may have their composition and bulk considerably altered, while the special senses, the temperature, and, in short, every function and tissue, may be more or less affected.

Some drugs given in excess are poisons to all forms of protoplasm, but when given in doses much short of the lethal they usually exhibit a distinct tendency to affect specially, and at an early period, certain organs or tissues, and hence result differences in action; others may act only on certain organs, leaving the others practically untouched. It is often possible by appropriate dosage to contrive that these special parts or organs may be affected and the rest of the body left practically intact, and it is by taking advantage of these selective actions that remedial or therapeutic effects are usually obtained. Some substances have a very wide range of action, and involve a great variety of structures, while others, such as purgatives, have a very limited sphere. The action of drugs is often modified by circumstances peculiar to the individuals or animals to whom they are administered. In man the most important of these circumstances is age, but speaking broadly this is really a question of bulk, the child being affected like the adult, but by smaller doses. There are exceptions to this, however, as children are more affected in proportion by opium and some other substances, and less by mercury and arsenic. In old age also the nervous system and the tissues generally do not react so readily as in youth. Habit, race, personal temperament, emotional conditions, disease, the time and circumstances of administration, and other accidental causes may also modify the action in man. Some species of animals are much more susceptible to the action of certain drugs than others, a condition which depends on obvious
or unknown structural or metabolic differences. In the same way some individuals show a special tendency to poisoning by doses of certain drugs which are harmless to the great majority of mankind, and hence we get unexpected or unusual results, these arising from special susceptibility on the part of certain organs. These idiosyncrasies are not confined to drugs, but are seen with a few articles of food, such as eggs and shellfish. It is well known that the habitual consumption of certain drugs, such as tobacco, Indian hemp, opium, arsenic, alcohol and many others, gradually induces a condition of tolerance to their effects, so that large doses can be taken without causing symptoms of poisoning. In all cases, however, there is a limit, and after it is reached the ordinary effects of these substances are seen. Some individuals, however, never become tolerant, and show poisonous effects on each repetition of the dose. The degree of tolerance often differs in individuals at different times and in different circumstances, and may become lost by breaking off the habit for a short time. The explanation generally given is that the nerve and other cells become accustomed to the drug, so that they cease to react, or that an antitoxin is formed which antagonizes the poison, or that the poison is rapidly destroyed in the body. Recent researches on arsenic and atropine, however, point to the leucocytes as playing an important part in the production of tolerance, as these gradually become capable of ingesting large amounts of the foreign substances, and thus render them more or less harmless to the tissues, until they are gradually excreted from the body. When the amount is too large to be dealt with by the leucocytes, poisoning seems to occur even in the most habituated. Tolerance is therefore analogous to, but not identical with, the immunity which takes place with the toxins of infectious diseases and snake poison. Certain substances, notably digitalis, lead, mercury and strychnine, exhibit what is called a cumulative action—that is to say, when small quantities have been taken over a period of time, poisoning or an excessive action suddenly ensues. The explanation in these cases is that the drug is absorbed more rapidly than it is excreted, hence there is a tendency to accumulation in the body until a point is reached when the amount becomes poisonous.

Bodies which have a close resemblance in their chemical constitution exhibit a similar resemblance in their pharmacological action, and as the constitution of the substance becomes modified chemically so does its action pharmacologically. Numerous researches have demonstrated these points with regard to individual groups of substances, but hitherto it has not been possible to formulate any fixed laws regarding the relationship between chemical constitution and physiological action.

When drugs are swallowed no absorption may take place from the alimentary canal; but, as a rule, they pass from there into the blood. Absorption may also take place from the skin, from the rectum, from the respiratory passages, or from wounds, and from direct injection into the subcutaneous tissue or into a blood vessel. Very rarely, as in the case of silver salts, excretion does not take place; but usually the drug is got rid of by the ordinary channels of elimination. Just as drugs act upon the tissues, so they themselves are in many cases reacted upon, and broken up or altered. While in the alimentary canal they are subjected to the action of the digestive fluids and the varied contents of the stomach and intestines, and after absorption they come under the influence of the constituents of the blood and lymph, and of the chemical action of the tissue cells. Inorganic bodies, such as metals, may enter into albuminous combinations which may greatly modify their effects, and organic substances may be split up into simpler compounds by oxidation or reduction, or may be rendered more complex by synthesis.

The antagonism between certain drugs has been much studied in relation to their use as antidotes in poisoning, the aim being to counteract the effects rather than to obtain a direct physiological antagonistic action. Substances which directly antagonize each other by acting on the same tissue are few in number, but there are numerous instances in which the effects or symptoms may be obviated by acting on another tissue. Thus curare may stop strychnine convulsions by paralysing the terminations of motor nerves, and chloroform may exercise the same effect by abolishing the irritability of the spinal cord. If two poisons act on the same tissue, one stimulating and the other paralysing it, the paralysing substance removes the action of the stimulant substance, not by bringing the tissue back to its normal state, but by abolishing its excitability; hence, although life may be saved by such an action, yet it can only be so within certain limits of dosage, because the antagonism is never complete at every point.

Speaking in the widest sense, every substance has an action on living protoplasm, but for convenience pharmacological substances have come to be limited to those which are used as drugs, or which have a distinct action upon the animal organism. Such substances are derived from (1) the chemical elements and their compounds; (2) plants; and (3) animals. The first class includes such substances as iodine, mercury, iron, carbon, and their various compounds, and such bodies as alcohol, chloroform and chloral, all of which are found in nature or can be prepared by ordinary chemical processes of manufacture. From plants many substances are obtained which at the present time we are unable to make in the chemical laboratory, and of the constitution or composition of which we are in many cases ignorant. Some of these, such as resins, gums, essential oils and fats, are readily obtained as natural exudations or by very simple manipulations, while others, such as the alkaloids, glucosides and vegetable acids, often require to be extracted by very complex processes. Substances obtained from animals include gland secretions, pepsin and other ferments, musk, cod-liver oil, &c., and to these may be added various antitoxins. The classification of substances having pharmacological actions presents so many difficulties that no satisfactory or universally adopted method has yet been proposed. Our knowledge presents so many gaps, and the mode of action of many remedies is so obscure and imperfectly understood, that any arrangement adopted must be more or less tentative in character.

The close alliance between pharmacology, therapeutics and clinical medicine has induced many authors to treat the subject from a clinical point of view, while its relationships to chemistry and physiology have been utilized to elaborate a chemical and physiological classification respectively as the basis for systematic description. Certain writers in despair have adopted an alphabetical method which has divided it up into inorganic, vegetable and animal substances. These last-mentioned methods are far behind our present state of knowledge, and need not be discussed here. The objection to a strictly chemical classification is, that while many substances closely allied chemically have a somewhat similar action in certain respects, yet in others they differ very widely—a striking example of which is given in the case of sodium and potassium. A physiological classification according to an action on the brain, heart, kidney or other important organ becomes still more bewildering, as many substances produce the same effects by different agencies, as, for instance, the kidneys may be acted upon directly or through the circulation, while the heart may be affected either through its muscular substance or its nervous apparatus. A clinical or therapeutic classification into such divisions as anaesthetics, expectorants, bitters, and so on, according to their practical applications, also leads to difficulties, as many drugs are employed for numerous purposes. The ideal method of grouping pharmacological substances would be in reference to their chemical action on living protoplasm, but as yet our knowledge is too scanty for this. At the present time the method adopted by Buchheim, or some modification of it, is the most scientific. As the result of painstaking investigations he grouped together all those substances having similar actions, giving to each group the name of its best-known or most thoroughly investigated member. Once the groups were more or less fixed any new substance could, when
its action was determined, be referred to its own group, and thus be placed or classified. As few substances are absolutely identical in action, but only broadly similar, it is often difficult to divide sharply one group from another. In a résumé it is manifestly impossible to pass in review every pharmacological substance, and we shall therefore confine ourselves to those groups which are of practical importance. Many individual drugs are described under their own headings.

GROUP I. Acids.—This includes sulphuric, hydrochloric, nitric, phosphoric, tartaric, citric, acetic and lactic acids, all of which exercise their action to their acidity. Many of the other acids, such as carbolic and salicylic, have specific effects which have no relationship to their acid reaction. The concentrated acids have an intense local action; the concentrated carbolic and salicylic acids are kept in small doses, being partially absorbed, and the remainder excreted. Most of them are slightly irritating, but only a few are absorbed in sufficient amount to produce similar effects when given by the mouth. When iron is injected directly into a vein it depresses the heart’s action, the blood pressure and the nervous system, and during its excretion great care must be taken to prevent it from entering the mouth. When given by the mouth, however, no such actions are seen, owing to the fact that very minute quantities are absorbed and that these become stored in the liver, where they are converted into organic compounds and utilised to form haemoglobin. When the iron has passed out, however, aluminium, zinc, copper, gold, platinum and bismuth have, when given by the mouth, little action beyond their local alantogenic or irritating effects; but when injected into a blood vessel they all exert much stronger action. In this case the iron becomes the cause of the saline cell. When injected into the mouth, silver resembles them closely, but differs by the circumstance that it is deposited permanently in minute granules in the tissues, and without affecting the general health, stains the skin of a bluish colour (erythria). Mercury and lead are absorbed from the bowel in considerable quantities, and are capable of inducing acute irritant poisoning as well as chronic poisoning. Lead poisons the muscular and nervous systems, and gives rise to paralysis, wasting, headache and other symptoms, while in the case of mercury, tremors, salivation, anaemia and very marked cachexia are induced.

GROUP II. Alkaloids.—This includes caustic potash, caustic soda, solution of ammonia, their carbonates and bicarbonates, borax, sodium carbonate, and the salts and fixed alkalis of the other bases, magnesium and magnesium carbonate. All these substances, apart from any other actions, exert a similar effect upon the body in virtue of their alkalinity. When they are taken internally in small amounts they act on the mucus, and the acids of the stomach, and increase the amount of saliva secreted, and also of mucus in the alimentary canal, and at the same time they increase the normal acid secretion of the stomach. After absorption into the blood, which they make somewhat more alkaline, they are excreted chiefly in the urine, and when taken in a sufficient quantity, the urine becomes alkaline. Some of them by stimulating the kidney cells act as diuretics, but others apparently lack this action. Caustic potash and caustic soda are locally very irritating, and destroy the tissue with marked necrosis. Sodium carbonate and calcium carbonate are insoluble, and, when taken in a sufficient quantity, they are absorbed into the body, and combine with a mucus in a manner which makes them soothing and astringent rather than irritating. Apart from alkaline effects, these metals differ considerably pharmacologically. Potassium and lithium have a stimulating action upon the nervous system, ammonium salts have a stimulating action, while sodium practically speaking is indifferent. Calcium and magnesium have actions somewhat similar to that of potassium. Many of these metals are absolutely indispensable for healthy existence, and are contained in sufficient amount in our ordinary dietary to supply the needs of the organism.

GROUP III. Easily absorbed Salts.—Sodium chloride may be taken as the type of those salts which diffuse readily, and are therefore easily absorbed. Sodium nitrate, potassium nitrate, potassium chloride, ammonium chloride, the alkaline iodides and bromides, are also taken in a similar manner. Locally they cause considerable irritation, and when swallowed in concentrated solution may cause vomiting. From the stomach and intestines they are rapidly absorbed, and rapidly excreted from the blood, increasing all the general metabolism. These effects are apparently due to their irritating action upon individual cells.

GROUP IV. Salts absorbed with difficulty.—This group includes the phosphates, carbonate of lithia, simple carbonates, soda ash, and tartrate of potash, citrate of magnesia, sodium phosphate, sodium tartrate and similar salts. Locally their action is slight, but when taken internally, dissolved in water, they are not absorbed from the alimentary canal. They evidently do not pass beyond the level, and therefore remain for the most part in the intestine, and as they attract and retain large quantities of water, and at the same time slightly stimulate the mucous membrane, they come to have a more or less powerful diuretic effect.

GROUP V. Heavy Metals.—These include iron, magnesium, aluminium, chromium, zinc, copper, silver, gold, platinum, lead, mercuric and ferrous. Of these compounds of the metals, some of these differ very greatly in their actions after absorption, whilst locally they have certain effects in common—chiefly to their chemical action on albumen. Their soluble salts combine with albumen, forming albuminoids, which are more or less insoluble, or caustic, while weaker ones are astrangent simply, or even soothing. They are all antiseptics. Their insoluble compounds are much less active locally than the soluble, and in many cases are only effective to the extent to which they are dissolved and absorbed.

Some metals are only absorbed from the alimentary canal to such a very limited amount that they exert no general action, while others readily pass into the blood and give rise to more or less marked effects. All of them injected into the blood in large doses act as muscle and nerve poisons, and during their excretion by the kidney produce various local effects. When swallowed, however, aluminium, zinc, copper, gold, platinum and bismuth have, when given by the mouth, little action beyond their local astringent or irritating effects; but when injected into a blood vessel they all exert much stronger action. When injected into the mouth, silver resembles them closely, but differs by the circumstance that it is deposited permanently in minute granules in the tissues, and without affecting the general health, stains the skin of a bluish colour (erythria). Mercury and lead are absorbed from the bowel in considerable quantities, and are capable of inducing acute irritant poisoning as well as chronic poisoning. Lead poisons the muscular and nervous systems, and gives rise to paralysis, wasting, headache and other symptoms, while in the case of mercury, tremors, salivation, anaemia and very marked cachexia are induced. Arsenic and antimony do not form combinations with albumen, but they both completely depress the central nervous system and circulation; and when injected into the body, they cause fatty degeneration of the viscera and disappearance of glycogen from the liver. Locally they are both very irritating, and antimony has a special tendency to cause vomiting.

GROUP VI. Alkalis.—Some sulphides and the compounds of boron, chlorine, in their free state or as compounds. Locally they are all three strongly irritant or caustic, owing to their chemical action on albumen. They are in addition powerful germicides, and by expelling the air from the skin, they cause a stinging and burning sensation in the skin, which is not very agreeable. This strong affinity for the hydrogen of organic compounds they often act as bleachers and desodorizers. Iodine has a special interest, as it is a necessary constituent of food, and is present in the secretion of the thyroid gland. They are, however, very strongly irritant to the skin, as the iodides, as such, have no very marked influence on the healthy body beyond their saline action. Alkaline bromides, in addition to their saline action, have in sufficient doses a depressing effect upon the central nervous system, and may also cause thrombosis of the heart. Chlorine compounds are not known to exercise any action of a similar kind.

GROUP VII. Sulphur.—Sulphur itself has no action, but when brought into contact with the substances it forms sulphides, sulphites and sulphurated hydrogen, and thereby becomes more or less irritant and antiseptic. In the bowel its conversion into sulphides causes it to act as a mild laxative. Baths containing sulphured hydrogen sulphides have a very pleasing effect on the skin, and stimulate the general metabolism.

GROUP VIII. Phosphorus.—This includes phosphides, and, according to some authorities, hypophosphites. Phosphorus is not absorbed from the cellular substances, but is absorbed into cells, and in the bones as phosphates. It is therefore, in some form or other, a necessary part of all life. When taken by the mouth phosphorus is an irritant poison in large doses; in small doses the only effects noticeable consist in an increased formation of albumen and connective tissue, although it is also supposed to exert a gently stimulating effect upon the nervous system.

GROUP IX. Oxygen.—When pure oxygen is inhaled, the only effect is a slight increase of the amount of the gas in the blood, but this has no particular physiological effect. The pharmacological action of hydrogen peroxide (H₂O₂), potassium permanganate, powdered charcoal and some other oxidizing agents depends on the result which is obtained on oxidizing the organic substances of the body.

GROUP X. Carbonic Acid.—Carbonic acid gas, carbolic oxide (CO) and some other irrespirable gases produce their effects practically by asphyxiation. When dissolved in water, however, carbonic acid begins to lose its irritant and antiseptic properties, and the mixture being absorbed more rapidly than plain water; hence its greater value in assuaging thirst. Nitrous oxide (laughing gas) was at one time believed to act simply by cutting off the supply of oxygen to the brain, but it is now known that it has a specific action on the central nervous system, causing a delirium, which is followed by paralysis of certain parts of the central nervous system, and hence its value as an anaesthetic; when given in small amounts mixed with air it produces a condition of exhilaration.
red gum, bad fruit, logwood and witch hazel, all of which are largely used as medicinals. In these the variety of tannic acid is not exactly the same, but although there are slight chemical differences, they all possess the power of tanning raw hides and of preserving meat. They are generally applied locally, and depend upon its power of precipitating albumen and of destroying germs. It thus acts as an astringent on all mucous membranes. After absorption into the blood it loses this effect, as, in a short time, it is precipitated out again, and then acts as a mordant with alkalis, both of which change nullity its action upon albumen.

GROUP XIII. Local Irritants.—Although some of the drugs already considered have a local irritant action, they produce other local effects. Those which do not have a marked poisonous action on heating depend entirely for their action on the local irritant action.

a. Those which act upon the alimentary canal: Simple bitters such as camomile, wood, columbo root, taraxacum, gentian, chireta, and many others, irritate gently the mucous membrane of the stomach and bowels, and by increasing the secretions improve the appetite and digestion. The astringent bitters such as chamomile, sarsaparilla, confection do not cause the purgatives to act on an irritating effect upon the mucous membrane and the neuro-muscular apparatus of the bowel, whereby the secretions and peristalsis are more or less increased, as the result of the astringent and tonic effect. Some of these, however, this may cause the discharge to be very watery (haemorragie cathartics), whereas, for example aloes, by acting gently on the lower part of the bowel and on its muscular coat, produce simply a laxative effect. The latter are the purgatives when injected subcutaneously or into the bowel, probably owing to their being excreted into the intestinal canal.

b. Those which act on the skin: The best known of these is cantharidin, which is a colourless crystalline body—cantharin—which is extremely irritating. On a mucous membrane or a delicate skin it exerts an irritant action, which occurs more quickly than on a thickened epithelium, such as the mucous membrane in the eyes and nose. In such cases it acts as a local anesthetic, as in some cases it may result redness, a blister, or an ulcer. Other substances, such as chrysarobin, mustard, pepper, &c. are also capable of irritating the skin, the effect produced varying from mere dilatation of the cutaneous vessels to destruction of tissue.

GROUP XIV. Male-fem.—This includes the male-fem., santonin, cuous, pomegranate bark, pumkin seeds and many other substances containing active principles which have a specific poisonous action which may be specially destroyed by their actions. In some cases it is very considerably, but are of little practical importance.

GROUP XV. Ethereal Oils.—This includes a very large number of substances which act on the skin, and on the mucous membrane of their respective body, such as benzoin, storax, salamis of Tolu and balsam of Peru. These act by exciting the kidneys and the sweat-glands, and thereby increase the excretion of urine and of sweat. They also increase the number of leucocytes in the blood, and the more irritating of them increase the flow of blood to the pelvic organs, and may thus stimulate the uterus, or in large doses cause abortion. The various camphors, such as laurel camphor, Boronico camphor, menthol and eucalyptin, are oxidized derivatives of camphor, and may all have a marked poisonous action on the skin, and destroy germs. The secretions of the eye, nose, and throat are often increased, and the irritant action may be augmented by the use of such substances.

GROUP XVI. Phenol.—This includes a very large number of bodies chemically allied to benzol, such as carbolic acid, sulphonat, carboxyl, cresotin, wood tar, coal tar, oil of cade, thymol, salicylic acid, laurinen, chloral hydrate, petrol, coal tar, benzoin, camphor, creosote, and many others. These all resemble carbolic acid more or less closely, and may be described as general protoplasm poisons. Locally, these are destructive and irritating effects vary a good deal, but the general effects of the irritation of the skin, nose, and throat are such as to make the use of these substances undesirable, and there are many antiseptics which have a much more marked action on the skin, and destroy germs, causing a smaller amount of irritation.

GROUP XVII. Alcohol. This group also includes a very large number of chemical bodies, only a few of which are mentioned here.

Ethyl alcohol is taken as a type of the action of methyl alcohol, amyl alcohol, propyl alcohol, ether, acetetic ether, parahydroxy, sulphonal, chloroform, methyl chloride, ethyl chloride, chlorid hydrate, butyliclchloride hydrate, and almost any number of derivatives from these. Some of them are so volatile that they produce their effects when inhaled, others when sprayed upon the skin cause intense cold and then anaesthesia; but taken in the broadest sense the action of all of them after absorption into the blood is very similar, and is exerted upon the central nervous system, more especially the medulla oblongata, in which it may cause a state of excitement, followed by intoxication or narcosis, and with large doses this passes into paralysis and death from depression of the respiratory centre or of the heart. Some doses of any of them may produce an effect similar to that of carbonic acid on the medulla oblongata, as a result of which the heart beats more rapidly and the blood circulates more freely; but larger doses have a general depressant effect upon the circulatory system. Under the influence of the drug the body temperature is diminished and the temperature falls. With some of them, such as chloral and chloridorm, the stimulating period is short compared with the narcotic period, while with others, such as ether, the reverse is the case. The narcotic action of the drug is generally that of apnoeic action, that is to say, of which the body is very much decreased in the body, and thereby exerts its characteristic effects.

GROUP XVIII. Nitrates.—This group contains anil nitrate, ethyl nitrate, methyl nitrate, nitroglycerin, sodium and potassium nitrates, erythrol-tetranitrate, and many other compounds containing nitrate in the body, and thereby exerts changes upon a considerable, but are of little practical importance.

GROUP XIX. Alkaloids.—This embraces a very large number of important pharmacological substances, which differ a good deal in the details of their action, but they all act upon muscle and nerve tissue. Some of them affect only certain portions of the nervous system, others have a much wider range of action, and may act in either case as stimulants or as depressants, and hence the symptoms produced by them vary very greatly.

Morphine and the other opium alkaloids (codeine, naranine, laudanine) and two prominent actions of a narcotic followed by a tetanic action. In morphine, on the higher animals at least, the narcotic action is very marked, the tetanizing action slightly so; while in the higher animals the narcotic effect, but a tetanizing action like that of sarsaparilla. Morphine is used in medicine upon the cerebrum and the medulla oblongata in man. It has in addition a markedly depressing action upon the respiratory centre, it lessens the rate of breathing, except the heat, and diminishes bowel peristalsis and the activity of the heart. It is also used to the birds, rabbits, dogs and most other animals. Cats, however, show marked symptoms of cerebral excitement and increase of the nervous system, and the effects of morphine, codeine and the other alkaloids are only slightly narcotic.

2. Strychnine and brucine very closely resemble each other in action, and under this heading curarine may also be included. These substances stimulate the gray matter in the spinal cord and cause tetanic action. They are also masked almost at once by paralysis of the terminations of the motor nerves.

3. Caffeine is the active principle in tea, coffee, kola, mate and guarana; theophyllin, a body closely allied to it, is found in coffee and chocolate. The latter is closely allied to the brucine, and both are found in the brain and cord, this being the foundation of their diuretic value and their use as nervine stimulants. They also markedly increase the secretion of urine by stimulating the secretory cells of the kidneys.

4. Cocaine is the active principle of the coca leaf, which is chewed
PHARMACOLOGY

as a stimulant-narcotic in Peru and Bolivia. Small doses excite the nervous system, while larger doses are depressant. The chief action of cocaine from a practical point of view is its power of paralysing the terminations of sensory nerves. They therefore lessen, among other actions, the reflex of the hiccough, paralysed the vagus, and in addition they have a stimulating action on the central nervous system. 6. Nicotine, piperidine and lobeline are the active principles of tobacco, i.e., nicotine, homatropine, dihydroxyquinoline, and tartrate. They are chiefly nervous stimulants. In large doses they are powerful nerve poisons, but as usually taken they exercise a gentle stimulant effect upon the nervous system. Pilocarpine has an action closely allied to that of nicotine, but as it is much less poisonous the effects produced by it are less injurious to health. It is capable of being utilized in medicine. Muscarine has a very close resemblance in action to pilocarpine. 7. Physostigmine, the active principle of the Calabar bean, acts chiefly on the muscles of the heart and is a cheap substitute for atropine. It contracts the pupil. 8. Conine, geiselineine and strychnine all exert a paralysing effect on the terminations of the motor nerves, to the implication of which the weakened gait and other symptoms are due. 9. Aconite, delphinine and many of their derivatives have a very widespread depressant action on the muscles. 10. In this connection, it is worth noting that minute doses stimulate the vomiting centre and cause emesis before any other symptoms are observable, its emetic action being the most prominent effect in man. 11. Atropine—this name has been given to a large number of substances which have an action similar to that of the oxglove leaves, including the active principles of straphanthus, squill, Urechites subserica, Consoliraria mexicana, Nerium oleander, Hyoscyamus niger, &c., and some other sharks and trees. The active principles of these vary a good deal in chemical composition, but they are all non-nitrogenous neutral bodies. Their action is exerted upon the muscles, and chiefly upon the muscular membranes and vessels of all parts. They contract and expand more perfectly, and thus the diastole and systole of the heart are rendered more complete, the pulse is slowed, and the blood-pressure is raised. The slowing of the heart is partly brought about by the action of the atropine on the secretory centres of the brain.
of its contents. Emetics (Gr. ῥεμος, vomiting) are substances given for the purpose of causing vomiting, e.g. ipecacuanha or apomorphine. Anti-emetics or Sedatives (Lat. sedare, to compose) arrest vomiting either by their central or local action, e.g. opium, cocaine, or by stimulating the walls of the alimentary canal, aid the onward passage of the contents of the intestinal canal, either by increasing the contractions of its muscular coat as laxatives (Lat. laxare, to loosen), e.g. as magnesium or by increasing the flow of the alimentary secretions, e.g. castor oil, oils (Lat. καθαρωτικα, cleansing), which produce watery evacuations. Cholagogues (Gr. χολη, bile, ἀγωγειν, leading) are purgatives which act by increasing the flow of bile, either by causing an increased secreted or by promoting (Lat. ἐπομενος) towards or by stimulating the intestinal contractions (e.g. calomel).

III. Drugs acting on parasites. Anthelmintics (Gr. άνθρωπος, against, άνθρωπως, a worm) are drugs which kill parasites inhabiting the bowels, e.g.: Vermicides (Gr. άνθρωπος, worm, φυσαλή, worm, ποταμος, to put to flight) are applied to drugs which directly kill the entozoa, while vermifuge (Lat. vermis, worm, fugare, to put to flight) is applied to the purgative usually given after the vermicide for the purpose of expelling the werecide. Parasiticide (e.g. vernicidal) or parasites; the terms are usually restricted to those acting on skin-parasites as contrasted with intestinal ones.

IV. Drugs acting on the urinary system. Diuretics (Gr. διορέω, through, δια, water, νεφος, to drain down) are drugs given to prevent the formation of urinary calculi.

V. Drugs acting on the generative system. Aphrodisiacs (Gr. αφρος, sexual desire) increase the sexual desire; or the centre in the spinal cord; Anaaphrodisiacs decrease its action. Ecotics (Gr. ηκςοδαιω, to throw out) or oxylytics (Gr. δρος, sharp, quick, σοριας, parturition) stimulate uterine action. Emmuncagi- gogues (Gr. καινους, a new, δακτυλος, finger) are substances which increase the menstrual flow. Galactogogues (Gr. γαλακτος, milk) increase the secretion of milk, while antagalactogogues (e.g. belladonna) have the opposite effect.

VI. Drugs acting on the respiratory system. Expectorants increase the bronchial secretions; antispasmodics relax the spasm of the muscular coat of the bronchial tubes, e.g. stramonium. This latter term is also used for drugs which act as general decontractants.

VII. Drugs or substances acting on the bodily heat. Anti- pyretics (Gr. άνθρωπος, against, πυρος, fever) either increase the heat loss or diminish its production; e.g. phenacetin, cold water, &c.

III. Drugs or substances acting on the skin. Diaphoretics (Gr. δια, through, φορης, blowing) are substances which stimulate the perspiration. They are either by acting directly on the sweat centres or on the nerve terminals. The word Sudorific (Lat. sudor, sweat) is applied to them when they act very powerfully. Anhidrotics or Antidiuretics (Gr. άνθρωπος, no, δακτυλος, finger) are substances which diminish or prevent the sweating. Emulsions (Lat. mollis, soft) are substances which soften and protect the parts. Demulcents (Lat. demulcere, soften), soothe the skin or mucous membrane.

IV. Drugs acting on metabolism. Alteratives are drugs which alter the course of a disease, the mode of action being unknown. Tonics are drugs which increase the muscular tone of the body by acting either on the stomach, heart, spinal cord, &c.

V. Drugs or substances acting on the blood. Blood purgatives are organic products designed to neutralize the formation of the toxins of certain diseases in the blood. Toxins are also injected in order to stimulate the blood plasma to form antitoxins (see Bacteriology). Antiperistaltics (Gr. αντι, against, περιστατικα, peristaltic) are substances which cause relaxation or tone in the alimentary tract. Haematinics are drugs which increase the amount of haemoglobin in the blood.

VI. Drugs acting on the nervous system. Anaesthetics (e.g., diminished sensibility, either central or peripheral; Anodynes (Gr. αναιρεσις, priv., δοξα, pain) relieve pain only, but, as in Analgetics (Gr. αναλγης, sense of pain), sensibility is unaltered. Stimulants are those which lead the excitation of the mental faculties and in quality (Gr. πονηρος, sharp pain) or nerve, or τερνος, sleep) or Somnifices (Lat. sopor, a deep sleep) are drugs which produce sleep without causing cerebral excitement. Narcotics (Gr. ναρκος, numbness) are those which besides producing sleep may induce large doses depress the functions of respiration and circulation.

XII. Drugs which arrest the progress of putrefaction. This is either by inhibiting the growth of micro-organisms (Antiseptics) or by destroying them when present (Disinfectants). (H. L. H.)

PHARMACOPOEIA (lit. the art of the pharmacon or, drug; compounder), in its modern technical sense, a book containing directions for the identification of simples and the preparation of compound medicines, and published by the authority of a government. The term was originally used by the pharmacopoeia, a name has also been applied to similar compendiums issued by private individuals. The first work of the kind published under government authority appears to have been that of Nuremberg in 1542; a passing student named Valerius Cordus showed a collection of medical receipts, which he had selected from the writings of the most eminent medical authorities, to the physicians of the town, who urged him to print it for the benefit of the apothecaries, and obtained for his work the sanction of the senatus. An earlier work, known as the Antidotarium florentinum, had been published under the authority of the college of medicine of Florence. The term "pharmacopoeia" first appears as a distinct title in a work published at Basel in 1501 by Dr A. Foes, but does not appear to have come into general use until the beginning of the 17th century. Before 1542 the works principally used by apothecaries were the treatises on simples by Avicenna and Serapion; the De synonymis and Quod pro quo of Simon Januensis; the Liber secretorius of Bulchasim Ben Abazeris, which described the preparations made from plants, animals and minerals, and was the type of the chemical portion of modern pharmacopoeias; and the Antidotarium of Nicolauis de Salerno, containing Galenic compounds arranged alphabetically. Of this last work there were two editions in use—Nicolauis magnus and Nicolauis parvus: in the latter several of the compounds described in the large edition were omitted and the formulae given on a smaller scale.

Until 1617 such drugs and medicines as were in common use were sold in England by the apothecaries and grocers. In that year the apothecaries obtained a separate charter, and it was enacted that no grocer should keep an apothecary's shop. The preparation of physicians' prescriptions was thus confined to the apothecaries, upon whom pressure was brought to bear to make them dispense accurately, by the issue of a pharmacopoeia in May 1618 by the College of Physicians, and by the power which the wardens of the apothecaries received in common with the executors of the College of Physicians of examining the shop of the apothecaries within 7 m. of London and destroying all the compounds which they found unfaithfully prepared. This, the first authorized London Pharmacopoeia, was selected chiefly from the works of Mezue and Nicolauis de Salerno, but it was intended to be full and complete, and as the whole edition was cancelled, and a fresh edition was published in the following December. At this period the compounds employed in medicine were often heterogeneous mixtures, some of which contained from 20 to 70, or more, ingredients, while a large number of simples were used in consequence of the same substance being supposed to possess different qualities according to the source from which it was derived. Thus crabs' eyes, pearls, oyster-shells and coral were supposed to have different properties. Among other ingredients entering into some of these formulæ were the excrements of human beings, dogs, mice, geese and other animals, calcui, human skull and moss growing on it, blind puppies, earthworms, &c. Although other editions of the London Pharmacopoeia were issued in 1621, 1632, 1639 and 1677, it was not until the edition of 1711, published under the auspices of Sir Hans Sloane, that any important alterations were made. In this issue many absurd and ridiculous remedies previously in use were omitted, although a good number were still retained, such as dogs' excrement, earthworms, and moss from the human skull; the botanical names of herbal remedies were for the first time added to the official ones; the simple distilled waters were ordered of a uniform strength; sweetened spirits, cordials and rye beers were omitted as well as several compounds no longer used in London, although still in vogue elsewhere. A great improvement was effected in the edition published in 1746, in which only those preparations were retained which had received the approval of the majority of the pharmacopoeia committee; to these was added a list of those drugs only which were supposed to be the most efficacious. An attempt was made to simplify further the older formulæ by the rejection of superfluous ingredients. In the edition published in 1788 the tendency to simplify was carried out to a much greater extent, and the extreme compound medicines which had formed the principal remedies of physicians for 2000 years were discarded, while a few powerful drugs which had been considered too dangerous to be included in the Pharmacopoeia of 1765 were restored to their previous position. In 1809 the French chemical nomenclature...
was adopted, and in 1815 a corrected impression of the same
was issued. Subsequent editions were published in 1824, 1836 and 1851.
The first Edinburgh Pharmacopoeia was published in 1699
and the last in 1841; the first Dublin Pharmacopoeia in 1807
and the last in 1850.
The preparations contained in these three pharmacopoeias
were not all uniform in strength, a source of much inconvenience
and danger to the public, when powerful preparations such as
dilute hydrocyanic acid were ordered in the one country
and dispensed according to the national pharmacopoeia in another.
In consequence of this inconvenience the Medical Act of 1858
ordained that the General Medical Council should cause to be
published a book containing a list of medicines and compounds
as was called the British Pharmacopoeia, which should be a substitute
throughout Great Britain and Ireland for the separate
pharmacopoeias. Hitherto these had been published in Latin.
The first British Pharmacopoeia was published in the English
language in 1864, but gave such general dissatisfaction both
in the medical profession and to chemists and druggists that
the General Medical Council brought out a new and amended edition
in 1867. This dissatisfaction was probably owing partly to the
fact that the majority of the compilers of the work were not
engaged in the practice of pharmacy, and therefore competent
rather to decide upon the kind of preparations required than
upon the method of their manufacture. The necessity for this
element in the construction of a pharmacopoeia is now fully
recognized in other countries, in most of which pharmacological
chemists are represented on the committee for the preparation
of the legally recognized manuals.

National pharmacopoeias now exist in the following countries:
Austria, Belgium, Chile, Denmark, France, Germany, Great Britain,
Greece, Holland, Hungary, India, Japan, Mexico, Norway, Portugal,
Russia, Sweden, Switzerland, the United States, and possibly also
America and Venezuela. All the above-mentioned were issued
under the authority of government, and their instructions have the force
of law in the respective countries, except that the United States
which has prepared by Commissioners appointed by medical
and pharmaceutical societies, has not, generally accepted as the national
textbook. The French Code has probably a more extensive use than any
other pharmacopoeia outside its own country, being, in connexion
with Dorvaut’s L’Office, the standard for druggists in a large
portion of Central and South America; it is also official in Turkey.
The sum-total of the drugs and preparations it contains is about
1250, and it is double the size of any pharmacopoeia previously
published. The progress of medical knowledge has led to a gradual but very
perceptible alteration in the contents of the pharmacopoeias. The
original very complex form have been simplified until only the
principal drugs and the preparations which are in common use
are retained. It is however required that in many cases the active principles have to a large extent replaced the crude
drugs from which they were derived. From time to time secret
remedies of druggists or physicians as have met with popular
or professional approval have been represented by simpler official
preparations.
The rapid increase in medical and pharmaceutical knowledge
nows necessitate frequent new editions of the national pharma-
copoeias, the office of which is to furnish definite formulae for pre-
parations that have already come into extensive use in medical
practice, so as to ensure uniformity of strength, and to give
the character of the tests by which their purity and potency may
be determined. But each new edition requires that many models have to
be carried out numerous experiments for devising suitable formulae, so that
the current Pharmacopoeia can never be quite up to date. This
difficulty has hitherto been met by the publication of such non-
national pharmacopoeias as Dr. Squire’s Companion to the Pharmacopoeia
and Martindale’s Extra Pharmacopoeia, in which all new remedies
and their preparations, uses and doses are recorded, and in the former the varying strengths of the same preparations in the different
pharmacopoeias. Further need of such works to supplement the Pharmacopoeia is shown by the fact that they are
are even more largely used than the Pharmacopoeia itself, the first
having been issued in 1862 and the second in 1873 in editions at compara-
tively low prices. Such Extra Pharmacopoeias show that the
Pharmacopoeia is entrusted to a body of a purely medical character,
and legally the pharmacist has not, as in other countries, a voice
in the matter, notwithstanding the fact that, although the medical
practitioner, or the dispensing chemist may be the best judge of the drug or preparations
that will afford the best therapeutic result, he is not so competent
as the pharmacist to say how that preparation can be produced in the
most effective and satisfactory manner, nor how the purity of
drugs can be tested. In the preparation of the fourth edition of

the British Pharmacopoeia in 1898 some new departures were made. A committee of the Pharmaceutical Society of Great Britain
was appointed at the request of the General Medical Council to advise
on pharmaceutical matters and the valuable assistance rendered
by the knowledge and skill of the Medical Council was offered. A census of
prescriptions was taken to ascertain the relative frequency with
which different preparations and drugs were used in prescriptions,
and suggestions and criticisms were sought from various medical
and pharmaceutical associations. The result of this work affords
the purely pharmaceutical part of the work a committee of refer-
ence in pharmacy, nominated by the pharmaceutical societies of
Great Britain and Ireland, was appointed to report to the Phar-
macopoieia Committee.
been produced. The standardization of preparations of patent medicines, as regards the amount of active principles they contain, can only conveniently and economically be done in operating on large quantities, and must naturally lead to the preparations being standardized, the amounts of the various ingredients, whether active or passive, but it is not yet certain that deterioration may not take place after standardization, in such as those of ergot or digitalis, so that it is somewhat questionable whether the standardization is of permanent value. The general principle which must be placed on the careful selection of the drug, and skill in its preparation and preservation by the retail pharmacist, who should be personally responsible for the quality and purity of the preparations he sells. Although the present form of pharmaceutical preparation has been adapted to the general and local requirements of all parts of the British Empire and has met with better success. With the aid of the different parallel preparations of the British Pharmacopoeia, the administrative divisions of the British Empire an Indian and Colonial addendum to the British Pharmacopoeia of 1898 was compiled and published in 1900 in which each article receives official sanction in the form of regulations or standards. It was regarded as a preparatory step to the publication of a complete imperial pharmacopoeia.

Several unofficial universal pharmacopoeias have been published in England, Fraternity, Pharmacopoeia (London, 1880); Scherger, Literatur-pharmacoceum (Leipzig and Sorau, 1822); Flint, Report on the Pharmacopoeias of all Nations (Washington, 1883). (E. M. H.)

**PHARMACOSIDERITE—PHARMACY**

PHARMACOSIDERITE, a mineral species consisting of hydrated basic ferric arsenate, 2FeAsO₄·Fe(OH)₃·3H₂O. Crystals have the form of small, sharply defined cubes of an olive- or grass-green colour, and occur together in considerable numbers on the matrix of the specimens. On account of its cubic form, the mineral was early known as "cube ore" (Ger., Würfelzir). The name pharmacosiderite, given by J. F. L. Hausmann in 1813, alludes to the arsenic and iron present (φάρμακον, poison, and ὄξως, iron). The faces of the cube are striated parallel to one diagonal, and alternate corners are sometimes replaced by faces of a tetrahedron. The crystals are feebly doubly refracting, and in polarized light exhibit a banded structure parallel to the cube faces. The hardness is 2½ and the specific gravity 2.8. Recent analyses prove the presence of a small but variable amount of potassium (K₂O, 2.65–4.13%) in the Cornish crystals, though in those from Hungary there is only a trace; this constituent appears to take the place of basic hydrogen in the above formula. A curious property is to be observed when a crystal of pharmacosiderite is placed in a solution of ammonia—in a few minutes the green colour changes throughout the whole crystal to red; on placing the red crystal in dilute hydrochloric acid the green colour is restored. Natural crystals are sometimes honey-yellow to brown in colour, but this appears to be due to alteration.

Pharmacosiderite is a mineral of secondary origin, the crystals occurring attached to gozany quartz in the upper part of veins of copper ore. It was found in some abundance at the end of the 18th century in the copper mines of the Mt Day district in Cornwall, and has since been found at a few other localities, for example, at Königberg near Schenkinitz in Hungary, and in the Tuscany district in Utah. (L. J. S.)

**PHARMACY**, a term which in the original Greek form signified the use of any kind of drug (φάρμακον), potion of spell, and hence also poison and witchcraft. In the modern signification it is applied to the art of preparing, preserving and compounding medicines, according to the prescriptions of physicians. It was used first in this sense in 1597.

In the earliest periods of the world’s history of which we have any record, this art, like that of the perfumer, was practised by a special class of the priesthood, as in the case of Eleazar (Num. iv. 16), and that of medicine by another class (Lev. xili.). Egyptian inscriptions indicate that the physician-priests sent their prescriptions to be dispensed by the priests when, accompanied by the chant of incantations and spells, they visited the sick. A papyrus of Sent, 3300 B.C., gives directions as to the preparation of prescriptions. In the Ebers papyrus, 1550 B.C., mention is made of blister, ointments, clysters, mineral and vegetable drugs. The art of the apothecary is alluded to very early in the Old Testament history (Exod. xiii. 25 X and Jos. xiii. 25). The oldest known pharmacopoeia is that of Solomon (Eccles. x. 9), but this word, which is translated par fumere in the French version, only indicates that the preparation of fragrant unguents and incense formed, even at that early date, a part of pharmacy, since the drugs mentioned, viz. galbanum, myrrh, stacte, frankincense, calamus, cassia and cinnamon, were all of them used in perfumes, even the myrrh being probably the kind distinguished at the present time in the Bombay market as perfumed myrrh or bissabul, which still forms an ingredient of the ointments used as incense in the temples in China. The myrrh mentioned in Gen. xxxvii. 35 is described under another Hebrew word, and refers to ladanum, a fragrant resin produced in Cyprus, and the use of this drug, as well as that of cinnamon and cassia, indicates even at that early period a knowledge of the products of Somaliland, Arabia and the East Indies and the existence of trade between the farther East and Egypt. China also at a very early period, the art of pharmacy was practised. Ching-Hong, a contemporary of Menes I. of Egypt, was learned in the art, and made decoctions and extracts of plants. The materia media of the Chinese at the present day affords an excellent illustration of the changes that have taken place in the use of drugs, and of the theories and superstitions that have guided the selection of these from the earliest ages, inasmuch as it still comprises articles that were formerly used in medicine, but have now been utterly discarded. Thus the doctrine of signatures is evident in the use of the celebrated Ginseng root of China, which, like that of the mandrake (Gen. xxi. 14–16), owed its employment to the fact that the root often divides into branches resembling the arms and legs of a man, and this resemblance gave rise to the belief that it conferred strength and virility. The same belief is shown in the botanical names applied to many plants, e.g. Pulmonaria, Hepatica, Scrophularia, and others.

The zoological names of plants and sometimes minerals are under the influence of the planets is shown in the older names of some of the metals, e.g. Saturn for lead, Venus for copper, and Mars for iron, and the belief that the colours of flowers 1 The Egyptians believed that the medicinal virtues of plants were due to the spirits which dwelt within them.
indicated the particular planet they were under led to their use in diseases and for constitutions supposed to be under the same planet. Physicians to this day head their prescriptions with a sign that originally meant an invocation to Jupiter, but now represents the word *recipe*.

The belief, which is still held by the Chinese, that the excrements of animals retain the properties and peculiarities of the animals from which they are derived, led to the use in medicine of these disgusting remedies, which are still sold in drug shops in China, and were only omitted from the English Pharmacopoeia as late as 1721. At that date the science of chemistry was very imperfectly known, and the real constituents of ordinary remedies so little understood that different virtues were attributed to different products containing the same constituents. Thus, prepared oyster-shells, coral, pearls, crabs’ “eyes” and burnt hart’s horn were regarded as specifics in different complaints, in ignorance of the fact that they all contain, as the chief ingredients, calcium phosphate and carbonate. The celebrated Gascoigne’s powder, which was sold as late as the middle of the 19th century, in the form of balls like sal prinella, consisted of equal parts of crabs’ “eyes,” the black tips of crabs’ claws, Oriental pearls, Oriental bezoar and white coral, and was administered in jelly made of hart’s horn, but was prescribed by physicians chiefly for wealthy people, as it cost about forty shillings per ounce. Superstition also entered largely into the choice of remedies. Thus various parts of criminals, such as the thighbone of a hanged man, moss grown on a human skull, &c., were used, and even the celebrated Dr Culpeper in the 17th century recommended “the ashes of the head of a coal black cat as a specific for such as have a skin growing over their sight.”

In course of time the knowledge of drugs, and consequently the number in use, gradually increased, and some of the preparations made in accordance with the art attained a celebrity that lasted for centuries. Thus diacynthion pluster was invented by Menocrates in A.D. 1, and was used by him for the same purposes as colchicum, introduced 2,000 years later. An election of opium, known as *Mithradatium*, was invented by Mithrades VI, king of Pontus, who lived in constant fear of being poisoned, and tested the effects of poisons on criminals, and is said to have taken poisons and their antidotes every day in the year. The prescription for the general antidote known as Mithradatium was found with his body, together with other medical MSS., by Pompey, after his victory over that king. The prescription was improved by Democrates and Andromachus, body physicians to Nero. The first was subsequently known as *Mithradatium Damocritus*, and the second as *Theriaca Andromachi*, the name *Theriaca* or *Tiriaca* being derived from the snake called *Tyrus*, the flesh of which was added to it by Andromachus. The former contained 55, or, according to some formula, 72 ingredients, and occurs in all the dispensatories, from that of Corvus Valerius up to the pharmacopoeias of the 19th century; and aromatic preparations of opium are still used, under the name of *Theriaka* in Persia. The Theriaca prepared at Venice had the highest reputation, probably because in Venice the component plants were exposed to the inspection of wise men and doctors for two months, to determine whether they were or were not fit for use. The apothecaries’ ordinance at Nuremberg provided that no *Theriaca* should in future be branded with the seal of the city unless it had been previously examined and declared worthy of the same by the doctors of medicine, and that every druggist must know the age of the *Theriaca* he sold. Inasmuch as its action changed very materially with age, “the buyer should in all instances be informed, so he may not be deceived.” The last public preparation of *Theriaca* took place at Nuremberg in 1754.

In A.D. 77-78 Dioscorides of Anazarba, in Cilicia, wrote his great work on materia medica, which still remains the most important work on the plants and drugs used in ancient times (of which about 400 were enumerated) and until the 17th century was held as the most valuable guide to medicinal plants and drugs extant. Nearly 100 years afterwards Galen, the imperial physician at Rome (A.D. 131-200), who was learned in surgery, pharmacy and materia medica, added about 200 more plants to those described by Dioscorides.

Galen believed in the doctrine of humours originated by Hippocrates, which supposes the condition of the body to depend upon the proper mixture of the four elements, hot, cold, moist and dry, and that drugs possess the same elementary qualities, and that on the principle of contraries one or other was indicated, e.g., a cooling remedy for a feverish state. This doctrine was held for many centuries, and drugs are classed by all the old herbalists as having one or other of these qualities in a greater or less degree. Galen is said to have invented hiera-picta, which he employed as an anthelmintic; it is still used in England as a domestic remedy. In the 6th century Alexander of Tralles used calcium for gout, iron for anaemia, and rhubarb in liver weakness and dysentery. The practice of pharmacy was extended by the Arabian physicians, and the separation of it from medicine was recognized in the 8th, and legalized in the 11th. century. The practice of “polypharmacy,” or the use of a large number of ingredients in prescriptions, which was common in the middle ages, was greatly due to the view enunciated by Alkekendo, and held by one of the Arabian schools of medicine: that the activity of medicine increases in a duplicate ratio when compounded with others; and it was only in the first half of the 18th century that the practice was altogether discontinued in the pharmacopoeias, although the theory was shown to be incorrect by Averroes in the 12th century.

The establishments for dispensing medicines at Cordova, Toledo and other large towns under Arab rule, were placed under severe legal restrictions. Frederick II. in A.D. 1233 passed a law, which remained in force for a long time in the two Sicilies, by which every medical man was required to give information against any pharmacist who should sell bad medicine. The pharmacists were divided into two classes, the *stationarii*, who sold simple drugs and non-magisterial preparations at a tariff determined by competent authorities, and the *confectionarii*, whose business it was to dispense scrupulously the prescriptions of medical men; all pharmaceutical establishments were placed under the surveillance of the college of medicine. In the monastic period pharmacy was to a great extent under the control of the religious orders, particularly the Benedictines, who, from coming into contact with the Arabian physicians, devoted themselves to pharmacy, pharmacology and therapeutics; but, as monks were forbidden to shed blood, surgery fell largely into the hands of barbers, so that the class of barber-surgeons came into existence, and the sign of their skill in blood-letting still appears in provincial districts in England in the form of the barber’s pole, representing the application of bandages.

In England the separation between medicine and pharmacy was somewhat later than on the continent of Europe. The earliest record of an apothecary’s shop in London was in 1345. The status of the apothecary, as subordinate to the physician in the time of Henry VIII., is evident from the following, out of 21 rules laid down by a prominent apothecary, who was a cousin of Thomas Cromwell: “His master must be at hand, with plenty of herbs and seeds and roots. He must read Dioscorides. He must have mortars, pots, filters, glasses and boxes clean and sweet. He must have two places in the shop, one most clean for physic, and the base place for chirurgical stuff. He is neither to increase nor to diminish the physician’s prescription; he is neither to buy nor to sell rotten drugs. He is only to meddle in his own vocation; and to remember that his office is only to be the physician’s cook.”

The drugs used by the physicians and apothecaries were purchased from the grossarii or sellers in gross, who were subsequently called grocers, some of whom specialized as druggists and others as chymists or chemists. The apothecaries, who were the pharmacists of those days, were not represented by any corporate body, but in the reign of King James I., in 1606, were incorporated with the Company of Grocers. This arrangement was not, however, approved of by the physicians, who obtained in 1617 a separate charter for the apothecaries, to the number of 114, which was the number of physicians then
practising in London. At the same time it was enacted that no
grocer should keep an apothecary's shop, and that no surgeon
should sell medicines, and that the physicians should have the
power to search the shops of the apothecaries within 7 m. of
London under a penalty of £100 in case of a refusal to permit
it. Soon after the apothecaries were formed into a separate
corporation they took into consideration means to prevent the
frauds and adulterations practised by the grocers and druggists,
and, to remedy the evil, established a manufactory of their own
in 1626 so that they might make preparations for their own
members. The frauds and adulterations were probably due in
part to the apothecaries, for Dr Merrit, a collegiate physician
of London, stated that "such chemists which sell preparations
honestly made complain that few apothecaries will go to the
price of them." The medicinal preparations which required
the aid of a furnace, such as mineral earths, were undertaken by
the chymists, who probably derived their name from the
Alchemists, who flourished from the 14th to the 16th centuries.
When the word was discovered to be derived from an Arabic
prefix and a Greek word the prefix was dropped. In the 19th
century the word chymist became altered to chemist, although
the original spelling is still continued to a small extent. The
curious signs on the coloured carboys in chemists' windows,
which were commonly to be seen until the middle of the 19th
century, were signs used by the alchemists to indicate various
chemical substances. In 1694 the apothecaries had increased
from 114 to nearly 1000, and many of them, having acquired
a knowledge of the uses of medicine, began to prescribe medicines
for their customers and to assume the functions of the physician,
who retorted in 1697 by establishing dispensaries, where medicines
could be procured at their intrinsic value, or at cost price. The
assistants employed at these dispensaries after a time appear
to have gone into business on their own account, and in this way
the dispensing chemists, as a class, appear to have originated.
In 1748 the Apothecaries' Corporation obtained a charter
empowering them to license apothecaries to sell medicines in
London, or within 7 m., and intended to use it to restrain
chemists and druggists from practising pharmacy, and to
prohibit physicians and surgeons from selling the medicines
they prescribed; but the apothecaries, by paying increased
attention to medical and surgical practice, had not only alien-
ated the physicians and surgeons, but materially strengthened
the position of chemists and druggists as dispensers of pre-
scriptions. When a further attempt was made in 1815 to bring
a bill into parliament including provisions for prohibiting the
practice of pharmacy by uneducated persons, and giving pre-
eminence to chemists over druggists, the proposal was received
in London, and, finding that the provisions of the bill were entirely in the
interests of the apothecaries, and directed against chemists and
druggists, the latter took measures to oppose it in parliament,
which were so far successful as to prevent apothecaries from
interfering in any way with, or obtaining any control over,
chemists and druggists. In 1841 another attempt was made by
the apothecaries to control the trade of chemists and druggists
on the ground that no adequate examination or education in
pharmacy existed, and that such should be instituted, and be
controlled by the apothecaries and physicians, but the latter
disclaimed any desire to take an active part in the matter. The
chemists and druggists, recognizing that no institution for the
systematic education and examination of chemists and druggists
existed in England, and that no proof could be given that each
individual possessed the necessary qualifications, declared that
this objection must be met, and that pharmacy must be placed
upon a more scientific footing. They therefore resolved upon
the foundation of a voluntary society, under the title of the Pharma-
cological Society of Great Britain, "for advancing the know-
ledge of chemistry and pharmacy, and promoting a uniform
system of education for those who should practise the same, also
for protecting the collective and individual interests and privi-
leges of all its members, in the event of any hostile attack in
parliament or elsewhere." This society was instituted in 1841.

PHARMACY

metropolis and provincial towns. On the 18th of February 1843
a royal charter of incorporation was granted to the society, and
a permanent status was thus acquired. Chemists in business
before the granting of the charter were entitled to join the
society as members, but those who wished to join it subsequently
could do so only on condition of passing an examination for the
purpose of testing their knowledge of pharmacy. A school of
pharmacy was instituted, and a museum and library were
started. The chemical laboratory in connexion with the school
was, when first instituted, the only one in England for teaching
purposes, and the museum is now reputed to be the best
pharmaceutical one in the world, the library now containing
about 13,000 volumes.

The examinations are three in number. The first is of a
preliminary character, qualifying for registration as a student or
apprentice; in lieu of this examination, certificates of matriculation
at a university, and those of certain other educational bodies,
are accepted. The second examination qualifies for registration as
a chemist and druggist. This is known as the minor examination,
and must be passed before anyone can legally dispense, compound
and sell scheduled poisons. The subjects included are systematic
botany, vegetable morphology and physiology, chemistry, physics,
materia medica, pharmacy, dispensing, poisons, the reading of
almanacs, and the use of a globe. The Poisons and Pharmacy Act of 1908 (section 4) has given the society
power to regulate the preliminary training, arrange a curriculum,
and divide the qualifying examination into two parts, so that an
examination of this kind is offered to the medical schools of the
Continent is likely to take place within a short period. Degrees in
science and pharmacy are granted by the universities of Manchester
and Glasgow, and other universities were in 1910 considering
the introduction of a pharmacy degree.

The third, or major examination, which qualifies for registration
as a pharmaceutical chemist, is not, like the minor, a compulsory
one, but ranks as an honours examination. The education for this
major examination is added to the curriculum, so as to enable them
to carry out the prescriptions of oculists; spectrum
analysis; the use of the polariscope and refractometer; the method
of applying Röntgen rays; the preparation of glandular secretions
and antitoxins; and the chemistry of remedies for the fungoid
diseases and insect pests of plants.

Those who have passed this examination are competent to perform
analysis of all kinds, and generally obtain the preference for various
appointments, such as head dispensers in government or other
large hospitals, or as analysts. The society has also established a
chemical research laboratory, in which much useful work has
been done in connexion with the national pharmacopoeia under
the direction of the Pharmacopoeia Committee of the Medical
Council.

A pharmacy act, which was passed in 1852, established a distinction
registered and examined, and unregistered and unexamined chemists and druggists, creating a register
of the former under the name of pharmaceutical chemists, so
that the public might discriminate between the two classes.
A subsequent pharmacy act, passed in 1868, added a register
of chemists and druggists, and rendered it unlawful for any
unregistered person to sell or keep open shop for selling the
poisons mentioned in the schedule of this act. The admin-
istration of the act was entrusted to the pharmaceutical society,
and the duty of prosecuting unauthorized practitioners has
been performed by the society ever since, without any pecu-
nary assistance from the state, although the legal expenses
involved in prosecution amount to a considerable portion of its
income.

The Poisons and Pharmacy Act of 1908 extended the schedule of
poisons instituted by the act of 1868, and it now includes arsenic,
aconite, aconitine and their preparations; all poisonous
vegetable alkaloids, and their salts and poisonous derivatives;
atropine and its salts and their preparations; belladonna and all
preparations or admixtures (except belladonna plasters) con-
taining 0·1 % or more of belladonna alkaloid; cantharides
and its poisonous derivatives; any preparation or admixture of
coca-leaves containing 0·1 % or more of coca alkaloids; corrosive
sublimate; cyanide of potassium and all poisonous cyanides
and their preparations; tartar emetic, nux vomica, and all
preparations or admixtures containing 0·2% or more of strychnine; opium and all preparations and admixtures containing 1%, or more of morphine; picro-toxin; prussic acid and all preparations and admixtures containing 0·1% or more of prussic acid; salvin and its oil, and all preparations or admixtures containing salvin or its oil. None of these may be sold to any person who is unknown to the seller, unless introduced by a person known to the seller, and not until after an entry is made in a book kept for the purpose, stating, in the prescribed form, the date of sale, name and address of purchaser, the name and quantity of the article sold, and the purpose for which it is stated by the purchaser to be required. The signature of the purchaser and introducer (if any) must be affixed to the entry.

The following poisons may not be sold, either retail or wholesale, unless distinctly labelled with the name of the article, and the word poison, with the name and address of the seller:—

Almonds, essential oil of (unless deprived of prussic acid). Anhydrous prussic acid is not a person in the eye of the law, and therefore does not come under the operation of the act of 1868. The result of this decision was that any chemist who failed to pass the qualifying examination could constitute himself with a few others, even if ignorant of pharmaceutical knowledge, into a limited liability company, which would then have been outside the powers of the act, and not subject to its provisions. This false position was remedied by the act of 1908, which brings companies into line with individuals.

On the continent of Europe the dispensing of prescriptions is confined to pharmacists (pharmacists and apothecaries). They are not allowed to prescribe, nor to the medical man to dispense, except under special licence, and then only in small villages, where the pharmacist could not make a living. The principle of "one man one shop" is general; a pharmacist may not own more than one shop in the same town. In Holland he may not enter into any agreement, direct or indirect, with a medical man with regard to the supply of medicines. In Austria, Germany, Italy, Rumania and Russia the number of pharmacies is limited according to the population. In France, Switzerland, Belgium and Holland the number is not limited, and every qualified pharmacist has the right to open a shop or buy a pharmacy. Where the number of pharmacies is limited by law prescriptions may only be dispensed at these establishments. The original prescription is kept by the pharmacist for either three or ten years, according to the country, and a certified copy given to the patient, written on white paper if for internal use, or on coloured paper (usually orange yellow) if for external use. The price of the drugs and the tariff for dispensing prescriptions is fixed by government authority.

In Russia a prescription containing any of the poisons indicated in the schedules A and B in the Russian pharmacopoeia may not be repeated, except by order of the doctor. The use of pharmacopoeia preparations made by manufacturers is allowed, but the seller is held responsible for their purity and strength. The prices charged for dispensing are lower in countries where the number of pharmacies is limited by law, the larger returns enabling the profit to be lessen.

The educational course adopted in different countries varies as to the details of the subjects taught. The preliminary, or classical examination, is usually that of university matriculation, or its equivalent. The period of study is eighteen months in Denmark or Norway, and two in Austria, Finland, Germany, Portugal, Russia, Sweden and Switzerland, three in Belgium, France, Greece and Italy, four to six in Holland, and five in Spain. In Great Britain the period of study is voluntary, and usually occupies only one year. Two or three years of apprenticeship is required in most countries, including Great Britain, but none in Belgium, Greece, Italy or Spain.

The subject of patent medicines is but little understood by the general public. Any medicine, the composition of which is kept secret, but which is advertised on the label for the cure of diseases, must in Great Britain bear a patent medicine stamp, equalling in both weight and face value. The British Medical Association published in 1907 a work on Secret Remedies; what they cost and what they contain. The analyses published in this work show that nearly all the widely advertised secret remedies contain only well-known and inexpensive drugs. The Pharmaceutical Society on the other hand has also published a Pharmaceutical Journal Formulary, including several hundred formulae of proprietary medicines sold by pharmacists, so that it is now possible for any medical man to ascertain what they contain. The government accepts all the herein published formulae as "known, admitted and approved" remedies, and therefore not requiring a patent medicine stamp. In this way widely advertised secret remedies can be replaced by medicines of known composition and accepted value in any part of the world. Most continental countries have issued stringent laws against the sale of secret remedies, and these have been lately strengthened in Germany, France, and Italy. In Switzerland secret remedies cannot be advertised without submitting the formula and a sample of the remedy to the board of health.
PHARNABAZUS, Persian soldier and statesman, the son of Pharnaces, belonged to a family which from 478 governed the satrapy of Phrygia on the Hellespont from its headquarters at Dascylium, and, according to a discovery by Th. Nöldeke, was descended from Otanes, one of the associates of Darius in the murder of Smerdis. Pharnabazus first appears as satrap of this province in 413, when, having received orders from Darius II., to send in the outstanding tribute of the Greek cities on the coast, he, like Tissaphernes of Caria, entered into negotiations with Sparta and began war with Athens. The conduct of the war was much hindered by the rivalry between the two satraps, of whom Pharnabazus was by far the more energetic and upright. After the war he came into conflict with Lysander (q.v.; see also PELOPONNESIAN WAR), who tried to keep the Greek cities under his own domination, and became one of the causes of his overthrow, by a letter which he sent to the ephors at Sparta (Plut. Lys. 16; Nepos, Lyc. 4; Polyæn. vii. 19). He received Alcibiades at his court and promised him means to go up to the king to reveal the intrigues of Cyrus, but when the Spartans insisted on his death he yielded to their demand for his assassination (Plut. Alcid. 2; Tac., ann. 40; Diod. xiv. 11). When in 390 the war with Sparta broke out again he again tried to conduct it strenuously. With the help of Conon and Evagoras of Salamis he organized the Persian fleet, and while he was hard pressed on land by Agesilaus he prepared the decisive sea-battle, which was fought in August 394 at Cnidus under his and Conon’s command, and completely destroyed the Spartan fleet. He sent support to the allies in Greece, by which the walls of the Peiraeus were rebuilt. But in the war on land he struggled in vain against the lethargy and disorganization of the Persian Empire; and when at last, in 387, in consequence of the embassy of Antalcidas to Susa, the king decided to conclude peace with Sparta and to enter again into close alliance with her, Pharnabazus, the principal opponent of Sparta, was recalled from his command in high honours, to marry Apane, a daughter of the king (Plut. Arilx. 27). In 385 he was one of the generals sent against Egypt, and in 377 he was ordered to prepare a new expedition against the valleys of the Nile. The gathering of the army took place, and when in 375 all was ready, his attempt to force the passage of the Nile failed. A conflict with Iphicrates, the leader of the Greek mercenaries, increased the difficulties; at last Pharnabazus led the army back to Asia. From these campaigns date the silver coins with the name of Pharnabazus in Aramaic writing. When he died is not known.

In the time of Alexander we meet with a Persian general Pharnabazus, son of Artabazus (Arrian ii. 1 seq.), who probably was the grandson of the older Pharnabazus. This Pharnabazus is also known by a king of Iberia (Georgia) on the Caucasus, where the dynasty seems to have been of Persian origin, deified by a general of Marcus Antonius (Mark Antony) in 36 B.C. (Do Cas. xix. 24). In the Georgian dynasty the name occurs as late as the 19th century. (Ed. M.)

PHARYNGITIS. The pharynx, or upper portion of the gullet (seen to a large extent on looking at the back of the mouth) is frequently the seat of a chronic inflammatory condition, usually associated with derangements of the digestive organs, or with smoking and excessive tobacco-smoking—especially of cigarettes. In inspection, the inflamed mucous membrane is seen unduly red and glazed, and dotted over with enlarged follicles. The condition produces considerable irritation and "dryness," with cough and discomfort, which may eventually become chronic. Treatment consists in removing all sources of irritation, in rectifying gastric disturbance, and in the application of the electric cautery, of astrigent lotions or of mild caustic solutions. The pain may be relieved by spraying with certain anodyne solutions. In the case of adenoid growths (see ADENOIDES) there is often an associated granular appearance of the pharynx, due to enlargement of the minute glands of the mucous membrane. The inflamed pharynx of the orator ("clergyman’s sore-throat") may be put right by lessons in elocution or by complete rest for a time. The gouty throat may call for a change of diet, or for a stay at one of the watering-places where early rising, moderate food, regular exercise and the drinking of laxative waters join in restoring health.

PHARYNX (Gr. φάρυγξ, throat), in anatomy, the cavity into which both the nose and mouth lead, which is prolonged into the oesophagus or gullet below, and from which the larynx or air tube comes off below and in front; it therefore serves as a passage both for food and air. It may be likened to an empty sack turned upside down and narrowing toward its mouth. The back and sides of the sack are formed by the three constrictor muscles of the pharynx, each of which overlaps the outer surface of the one above it, and these are lined internally by thick mucous membrane. The upturned bottom of the sack is attached firmly to the base of the skull and the internal pterygoid plates, so that this part cannot collapse, but below the anterior and posterior walls are in contact, and a transverse section of the pharynx is a mere slit.

From the front wall, on a level with the floor of the nose and root of the mouth, a slanting shelf of muscular and glandular tissue covered with mucous membrane, projects downward and backward into the cavity, and divides it into an upper part or naso-pharynx and a lower or oral pharynx (see fig.). This shelf is the soft palate, and from the middle of its free border hangs a worm-like projection, of variable length but averaging about half an inch, the uvula. This is the front of the floor of the naso-pharynx, and here the cavity opens into the nose through the posterior nasal apertures (see OLFACTORY SYSTEM). On each side of the naso-pharynx, and therefore above the soft palate, is the large triangular opening of the Eustachian tube, which leads into the tympanum (see EAR). Beyond this opening, and reaching up to the roof of the naso-pharynx, is a mass of lymphoid tissue, most marked in children, known as the pharyngeal tonsil. This tissue, which is one of the lymphatic organs, is described as "pyriform" or "pear-shaped." From the mid-line of the roof of the pharynx a small pouch, the bursa pharyngea, best seen in childhood, projects upward, while on each side, above and behind the opening of the Eustachian tube, is a depression known as the adenoid of the pharynx.

The oral pharynx communicates with the naso-pharynx by the pharyngeal isthmus behind the free edge of the soft palate. Above and in front it is continuous with the cavity of the mouth, and the connection is bridged by a ridge of mucous membrane on each side running from the soft palate to the side of the tongue, and caused by the projection of the palato-glossus muscle. This is known as the anterior pillar of the fauces or anterior palate line. This half an inch behind this ridge is another, made by the palato-pharyngeal muscle, which gradually fades away in the side of the pharynx below. This is the posterior pillar of the fauces or posterior palate arch, and between it and the anterior is the fossa (tonsilar sinus) in which the tonsil lies. (Ed. M.)

The tonsil is an oval mass of lymphoid tissue covered by mucous membrane which dips in to form mucous crypts; externally its position nearly corresponds to that of the angle of the jaw. It is very vascular, deriving its blood from five neighbouring arteries. Below the level of the tonsil the pharynx is opened into by the posterior or pharyngeal surface of the tongue (q.v.), while below that is the epiglottis and upper opening of the larynx which is bounded laterally by the aryteno-epiglottic folds (see RESPIRATORY SYSTEM). On the lateral side of each of these folds is a pear-shaped fossa known as the sinus pyriformis. Below this the pharynx narrows rapidly until the level of the lower border of the cricoid cartilage in front and of the sixth cervical vertebra behind; here it passes into the oesophagus, having reached a total length of about five inches.

The mucous membrane of the naso-pharynx, like that of the rest of the respiratory tract, is lined by ciliated columnar epithelium, but here the human pharynx differs from the domesticated variety. Numerous racemose glands are present (see EPITHELIAL TISSUES), as well as patches of lymphoid tissue especially in childhood. Outside the mucous membrane and separating it from the coat of muscles which form the lateral sides of the pharynx, which blends above with the peritoneum of the base of the skull.

Embryology.—The pharynx is partly formed from the ectodermal stomatodaeal invagination (see EMBRYOLOGY and MOUTH) and subsequently from the mesodermal mesodermal madrepor. Up to the fifteenth day (see MOUTH), the buccopharyngeal membrane separates these structures, and, though no vestiges of it, it remains, it is clear that the upper and front part of the pharynx begins as an oral diverticulum.

The five visceral arches with their intervening clefts or pouches surround the pharynx, and the Eustachian tube is a remnant of the first of these. The second pouch is represented in the adult by the tonsilar sinus, and until lately the lateral recess of the pharynx was looked upon as part of the same, but it has now been shown to be an independent diverticulum. The sinus pyriformis probably represents that part of the fourth groove from which the lateral lobes of the thyroid body are derived.
The Bursa pharyngae was at one time looked upon as the place whence the pituitary body had been derived from the roof of the pharynx, but this is now disproved and its meaning is unknown. The tonsil is formed in the second branchial cleft or rather pouch, for the clefts are largely incomplete in man, about the fourth month; its lymphoid tissue, as well as that elsewhere in the pharynx, is formed from lymphocytes in the subjacent mesenchyme (see Embryology), though whether these wander in from the blood or are derived from original mesenchyme cells is still doubtful. Sagittal Section through Mouth, Tongue, Larynx, Pharynx and Nasal Cavity.

The section is slightly oblique, and the posterior edge of the nasal septum has been preserved. The specimen is viewed slightly from below, hence in part the low position of the inferior turbinate bone.

Development of the ventral part of the pharynx is dealt with in the articles TONGUE and RESPIRATORY SYSTEM.

Comparative Anatomy.—In the lower, water-breathing, vertebrates the pharynx is the part in which respiration occurs. The water passes in through the mouth and out through the gill slits where it comes in contact with the gills or branchiae.

The lowest subphylum of the phylum Chordata, to which the term Adelochorda is sometimes applied, contains a worm-like creature Balanoglossus, in which numerous rows of gill slits open from the pharynx, though Cephalodiscus, another member of the same subphylum, has only one pair of these.

In the subphylum Urochorda, to which the Ascidians or sea-squirts belong, there are many rows of gill slits, as there are also in the Acrania, of which Amphioxus, the lancelet, is the type. In all these lower forms there are no true gills, as the blood-vessels lining the large number of slits provide a sufficient area for the exchange of gases.

In the Cyclostomata a reduction of the number of gill slits takes place, and an increased area for respiration is provided by the gill pouches lined by pleated folds of endodermal mucous membrane;

These form the simplest type of true internal gills. In the larval lamprey (Ammocoetes) there are eight gill slits opening from the pharynx, but in the adult (Petromyzon) they are reduced to seven, and a septum grows forward separating the ventral or branchial part of the pharynx from the oral or gill-bearing part. Both these tubes, however, communicate near the mouth.

In fishes there are usually five pairs of gill slits, though a rudimentary one in front of these is often present and is called the labial arch.

Hemionymphae, where, there may be six or seven slits, and the evidence of comparative anatomy is that fishes formerly had a larger number of gill slits than at present.

In the Teleostomi, which include the bony fishes, there is an external gill cover or operculum.

In the Dipnoi or mud fish the work of the gills is shared by that of the lungs, and in the African form, Protopterus, external gills, developed from the ectodermal parts of the gill slits, appear. In the tadled Amphibians (Urodela) the first and fifth gill slits are never perforated and are therefore in the same condition as all the other gill slits of the amphioxus embryo, while in the lobe salamanders (Necturus and Proteus) only two gill slits remain patent. The gills in all the Amphibia are external and of ectodermal origin, but in the Amphibians (frogs and toads) these arc succeeded before the metamorphosis from the tadpole stage by internal gills, which, unlike those of fish, are said to be derived from the ectoderm.

In the embryos of the Sauropsida (reptiles and birds) five gill slits are evident, though the posterior two are seldom at any time perforated, while in the Mamillaria the rudiments of the fifth gill are not longer found in the embryo, and in man, at all events, none of them are normally perforated except that part of the first which forms the Eustachian tube. It will thus be seen that in the process of phylogeny there is a gradual suppression of the gill slits beginning at the more posterior ones.

The soft palate is first found in crocodiles as a membranous structure, and it becomes muscular in mammals. The bursa pharyngae and pharyngeal tonsil are found in several of the lower mammals, in the sheep the latter is particularly large.

For literature and further details, see R. Wiedersheim’s Comparative Anatomy of Vertebrates, translated by W. N. Parker (London, 1907); also Parker and Haswell’s Zoology (London, 1897).

PHEASANT (Mid. Eng. faisant and fessan; Ger. fasan and anciently fassant; Fr. faisant—all from the Lat. phasianus or phasiana, sc. avis), the bird brought from the banks of the river Phasis, now the Rioni, in Colchis, where it is still abundant, and introduced, according to legend, by the Argonauts into Europe. Judging from the recognition of the remains of several species referred to the genus Phasianus both in Greece and in France, it seems impossible that the ordinary pheasant, the P. colchicus of ornithologists, may have been indigenous to this quarter of the globe. If it was introduced into England, it must almost certainly have been brought by the Romans; for, setting aside several earlier records of doubtful authority, Stubbs has shown that by the regulations of King Harold in 1059 unus phasianus is prescribed as the

1 These are P. archiaci from Pikermi, P. altus and P. medius from the lacustrine beds of Sanan, and P. desnoyersii from Touraine, see A. Milne Edwards, Ois. foss. de la France (ii. 225, 239-243).
2 Undoubted remains of fossil pheasants have been discovered in the Carboniferous limestone.
3 Among these perhaps that worthy of most attention is in Probert’s translation of The Ancient Laws of Cambria (ed. 1823, pp. 367, 368), wherein extracts are given from Welsh triads, presumably of the age of Howell the Good, who died in 1130, that of them is: “There are three barking huns: a bear, a squirrel and a pheasant.” The explanation is: “A pheasant is called a barking hunt, because when the pointers come upon it and chase it, it takes to a tree, where it is hunted by bating.” The present writer has not been able to trace the manuscript containing these remarkable
alternative of two partridges or other birds among the "pitantae" (nations or commons, as we might now say) of the canons of Waltham Abbey, and, as W. B. Dawsim has remarked (Ihis, 1869, p. 358), neither Anglo-Saxons nor Danes were likely to have introduced it into England. It seems to have been early under legal protection, for, according to Dugdale, a licence was granted in the reign of Henry I. to the abbey of Amesbury to kill hares and pheasants, and from the price at which the latter are reckoned in various documents, we may conclude that they were not very abundant for some centuries, and also that they were occasionally artificially reared and fattened, as appears from Upton, who wrote about the middle of the 15th century, while Henry VIII. seems from his privy purse expenses to have had in his household in 1532 a French priest as a regular "fessant breeder," and in the accounts of the Kytsons of Hengrave in Suffolk for 1607 mention is made of wheat to feed pheasants, partridges and quails.

The practice of bringing up pheasants by hand is now extensively followed, and the numbers so reared vastly exceed those that are bred at large. The eggs are collected from birds that are either running wild or kept in pens, and are placed under domestic hens; but, though these prove most attentive foster-mothers, much additional care on the part of their keepers is needed to ensure the arrival at maturity of the pouls; for, being necessarily crowded in a comparatively small space, they are subject to several diseases which often carry off a large proportion, to say nothing of the risk they run by not being provided with proper food, or by meeting an early death from various predatory animals attracted by the assemblage of so many helpless victims. As they advance in age the young pheasants readily take to a wild life, and indeed can only be kept from wandering in every direction by being plentifully supplied with food, which has to be scattered for them in the coverts in which it is known that they should stay. The proportion of pheasants artificially bred that "come to the gun" would seem to vary enormously, not only irregularly according to the weather, but regularly according to the district. In the eastern counties of England, and some other favourable localities, perhaps three-fourths of those that are hatched may be satisfactorily accounted for; but in many of the western counties, though they are the objects of equal or even greater care, it would seem that more than half of the number that live to grow their feathers disappear inexplicably before the coverts are beaten. For the sport of pheasant-shooting see SHOOTING.

Formerly pheasants were taken in snares or nets, and by hawking; but the crossbow was also used, and the better to obtain a "sitting shot,"—for with that weapon men had not learnt to "shoot flying"—dogs appear to have been employed in the way indicated by the lines under an engraving by Hollar, who died in 1677:

"The Peasant Cocke the woods doth most frequent. Where Spaniells spring and pearch him by the sent."

Of the many other species of the genus Phasianus, two only can be dwelt upon here. These are the ring-necked pheasant of China, P. torquatus, easily known by the broad white collar, whence it has its name, as well as by the pale greyish-blue of its upper wing-coverts and rump and the light buff of its flanks, and the P. versicolor of Japan, often called the green pheasant statements so as to mean the same thing is given by Ray (Synopsis, math. animalium, pp. 213, 214) on the authority of Llwyd or Llloyd, though there is no mention of it in Worton and Clarke's Leges Walliae (1730). A charter (Kemble, Cod. diplom. iv. 236), professedly of Edward the Confessor, granting the wardship of certain forests in Essex to Ralph Peperic, speaks of "fessant hen" and "fessant cocke," but is now known to be spurious.

1 In his De studio militar (not printed till 1654) he states (p. 195) that the pheasant was brought from the East by "Palladius angoris.

2 Quoted by the writer (Broderip?) of the article "Spaniel" in the Penny Cyclopedia. The lines throw light on the asserted Welsh practice mentioned in a former note.

from the beautiful tinge of that colour that in certain lights pervades almost the whole of its plumage, and, deepening into dark emerald, occupies all the breast and lower surface that in the common and Chinese birds is barbed with glossy black scallops. Both of these species have been introduced into England, and cross freely with P. colchicus, while the hybrids of each with the older inhabitants of the woods are not only perfectly fertile inter se, but cross as freely with the other hybrids, so that birds are frequently found in which the blood of the three species is mingled. The hybrids of the first cross are generally larger than either of their parents, but the superiority of size does not seem to be maintained by their descendants.

White and pied varieties of the common pheasant, as of most birds, often occur, and with a little care a race or breed of each can be perpetuated. A much rarer variety is sometimes seen; this is known as the Bohemian pheasant, not that there is the least reason to think that in any way the Bohemians have a right to such an epithet, for it appears, as it were, accidentally among a stock of the pure P. colchicus, and offers an example analogous to that of the Japan peafowl (see Peacock), being, like that breed, capable of perpetuation by selection. Two other species of pheasant have been introduced to the coverts of England—P. versicolor from China, remarkable for its very long tail, white with black bars, and the copper pheasant, P. soemmerringi, from Japan. The well-known gold and silver pheasants, P. pictus and P. nycthemerus, each of the type of a distinct section or subgenus, are both from China and have long been introduced into Europe, but are only fitted for the aviary. To the former is allied the still more beautiful P. amherstiae, and to the latter about a dozen more species, most of them known to Indian sportsmen by the general name of "kalebe." The comparatively plain pucas pheasants, Puerassia, the magnificent monalops, Lophophorus, and the fine snow- pheasants, Sclateripheasants, of each of which genera there are several species, may also be mentioned.

All the species known at the time are beautifully figured from drawings by J. Wolf in D. G. Elliot's Monograph of the Phasianidae (2 vols., fol., 1870-1872)—the last term being used in a somewhat more extended sense. With a more microscopic eye, W. de G. Belchier's Pheasants: their Natural History and Practical Management (4th ed., 1904) is to be commended as a very useful work. (A. N.)

PHIEDIAS, son of Charmides, universally regarded as the greatest of Greek sculptors, was born at Athens about 500 B.C. We have varying accounts of his training. Hegias of Athens, Agesilas of Argos, and the Thasian painter Polynotus, have all been regarded as his teachers. In favour of Agesilas it may be said that the influence of the many Dorian schools is certainly to be traced in some of his work. Of his life we know little apart from his works. Of his death we have two discrepant accounts. According to Plutarch he was made an object of attack by the political enemies of Pericles, and died in prison at Athens. According to Phidias, as quoted by a scholar on Aristophanes, he fled to Elys, where he made the great statue of Zeus for the Eleans, and after two years put to death by them. For several reasons the first of these tales is preferable.

Plutarch gives in his life of Pericles a charming account of the vast artistic activity which went on at Athens while that statesman was in power. He used for the decoration of his own city the money furnished by the Athenian allies for defence against Persia: it is very fortunate that after the time of Xerxes Persia made no deliberate attempt against Greece. "In all these works," says Plutarch, "Phidias was the adviser and overseer of Pericles." Phidias introduced his own portrait and that of Pericles on the shield of his Parthenon statue. And it was through Phidias that the political enemies of Pericles struck him. It thus abundantly appears that Phidias was closely connected with Pericles, and a ruling spirit in the Athenian art of the period. But it is not easy to go beyond this general assertion into details.

It is important to observe that in resting the fame of Phidias upon the sculptures of the Parthenon we proceed with little evidence. No ancient writer ascribes them to him, and he seldom, if ever, executed works in marble. What he was celebrated
for in antiquity was his statues in bronze or gold and ivory. If Plutarch tells us that he superintended the great works of Pericles on the Acropolis, this phrase is very vague. On the other hand, inscriptions prove that the marble blocks intended for the pedimental statues of the Parthenon were not brought to Athens until 434 B.C., which was probably after the death of Pheidias. And there is a marked contrast in style between these statues and the certain works of Pheidias. It is therefore probable that most if not all of the sculptural decoration of the Parthenon was the work of pupils of Pheidias, such as Alcamenes and Agoracritus, rather than his own.

The earliest of the great works of Pheidias were dedications in memory of Marathon, from the spoils of the victory. At Delphi he erected a great group in bronze including the figures of Apollo and Athena, several Attic heroes, and Miltiades the general. On the Acropolis of Athens he set up a colossal bronze image of Athena, which was visible far out at sea. At Pellec in Achaia, and at Plataea he made two other statues of Athena, also a statue of Aphrodite in ivory and gold for the people of Elis. But among the Greeks themselves the two works of Pheidias which far outshine all others, and were the basis of his fame, were the colossal figure of Zeus at Olympia and of Athena Parthenos at Athens, both of which belong to about the middle of the 5th century. Of the Zeus we have unfortunately lost all trace save small copies on coins of Elis, which give us but a general notion of the pose, and the character of the head. The god was seated on a throne, every part of which was used as a ground for sculptural decoration. His body was of ivory, his robe of gold. His head was of somewhat archaic type: the Otricoli mask which used to be regarded as a copy of the head of the Olympic statue is certainly more than a century later in style. Of the Athena Parthenos two small copies in marble have been found at Athens (see Greek Art, fig. 38) which have no excellence of workmanship, but have a certain evidential value as to the treatment of their original.

It will be seen how very small is our actual knowledge of the works of Pheidias. There are many stately figures in the Roman and other museums which clearly belong to the same school as the Parthenos; but they are copies of the Roman age, and not to be trusted for the parent style. A Furtwängler has proposed to find in a statue of which the head is at Bologna, and the body at Dresden, a copy of the Lemnian Athena of Pheidias; but his arguments (Masterpieces, at the beginning) are anything but conclusive. Much more satisfactory as evidence are some 5th century torsos of Athena found at Athens. The very fine torso of Athena in the École des Beaux Arts at Paris, which has unfortunately lost its head, may perhaps best serve to help our imagination in reconstructing a Pheidian original.

As regards the decorative sculptures of the Parthenon, which the Greeks rated far below their colossal in ivory and gold, see the article Parthenon.

Ancient critics take a very high view of the merits of Pheidias. What they especially praise is the ethos or permanent moral level of his works as compared with those of the later "pathetic" school. Demetrius calls his statues sublime, and at the same time precise. That he rode on the crest of a splendid wave of art is not to be questioned: but it is to be regretted that there is no record of work extant for which we can definitely hold him responsible.

(P. G.)

PHEIDON (8th or 7th century B.C.), king of Argos, generally, though wrongly, called "tyrant." According to tradition he flourished during the first half of the 8th century B.C. He was a vigorous and energetic ruler and greatly increased the power of Argos. He gradually regained sway over the various cities of the Argive confederacy, the members of which had become practically independent, and (in the words of Ephorus) "re-united the broken fragments of the inheritance of Temenus." His object was to secure predominance for Argos in the north of Peloponnesus. According to Plutarch, he attempted to break the power of Corinth, by requesting the Corinthians to send him 10000 of their picked youths, ostensibly to aid him in war, his real intention being to put them to death; but the plot was revealed. Pheidon assisted the Pisatans to expel the Elean superintendents of the Olympic games and presided at the festival himself. The Eleans, however, refused to recognize the Olympiad or to include it in the register, and shortly afterwards, with the aid of the Spartans, who are said to have looked upon Pheidon as having ousted them from the headship of Greece, defeated Pheidon and were reinstated in the possession of Pisatia and their former privileges. Pheidon is said to have lost his life in a faction fight at Corinth, where the monarchy had recently been overthrown. The affair of the games has an important bearing on his date. Pausanias (vi. 22, 2) definitely states that Pheidon presided at the festival in the 8th Olympiad (i.e. in 745 B.C.), but in the list of the suitors of Agariste, daughter of Cleisthenes of Sicyon, given by Herodotus, there occurs the name of Leocedes (Lacedas), son of Pheidon of Argos. According to this, Pheidon must have flourished during the early part of the 6th century. It has therefore been assumed that Herodotus confused two Pheidons, both kings of Argos. The suggested substitution in the text of Pausanias of the 28th for the 8th Olympiad (i.e. 668 instead of 745) would not bring it into agreement with Herodotus, and could not have been a surn of 570 for the hand of Agariste. But the story of Agariste's wooing resembles romance and has slight chronological value. On the whole, modern authorities assign Pheidon to the first half of the 7th century. Herodotus further states that Pheidon established a system of weights and measures throughout Peloponnesus, to which Ephorus and the Parian Chronicle add that he was the first to coin silver money, and that his mint was at Aegina. But according to the better authority of Herodotus (i. 94) and Xenophanes of Colophon, the Lydians were the first coiners of money at the beginning of the 7th century, and, further, the oldest known Aeginetan coins are of later date than Pheidon. Hence, unless a later Pheidon is assumed, the statement of Ephorus must be considered unhistorical. No such difficulty occurs in regard to the weights and measures; it is generally agreed that a system was already in existence in the time of Pheidon, into which he introduced certain changes. A passage in the Aristotelian Constitution of Athens (x. 2) states that the measures used before the Solonian period of reforms were called "Pheidonian."

See Herodotus vi. 127; Ephorus in Strabo viii. 558, 376; Plutarch, Amatoriae narrationes, 2; Marmor parium, ep. 30; Pollux ix. 83; Nicolaus Damascenus, frag. 41 (in C. W. Müller's Frag. hist. graecorum, iii.); G. Groce, History of Greece, pt. ii. ch. 4.; B. V. Head, History Numorum (1887); F. Hultsch, Griechische und römische Münzen (1882); G. Rawlinson's Herodotus, appendix, bk. i. note 8. On the question of Pheidon's date, see J. B. Burri, History of Greece, ii. 468 (1902); J. P. Mahaffy, Problems in Greek History, ch. 3 (1892); J. G. Frazer's note on Pausanias vii. 22, 2; and especially G. Busolt, Griechische Geschichte (2nd ed., 1893), ch. iii. 12; C. Triebel, Pheidon von Argos (Hanover, 1880), and J. Beloch, in Rheinisches Museum, xiv. 595 (1890), favour a later date, about 580.

PHELPS, AUSTIN (1820–1890), American Congregational minister and educationalist, was born on the 7th of January 1820 at West Brookfield, Massachusetts, son of Eliakim Phelps,1 a clergyman, who, during the boyhood of his son was principal of a girls' school in Pittsfield, Massachusetts, and later pastor of a Presbyterian church in Geneva, New York. The son studied at Hobart College in 1836–1837; then at Amherst for a year, and in 1837 graduated at the university of Pennsylvania. He studied theology at Union Theological Seminary, at the Yale Divinity School, and at Andover, and was licensed to preach in 1845 by the Third Presbyterian Church of Philadelphia. He was pastor of the Pine Street (Congregational) Church in Boston in 1842–1845, and in 1848–1879 was professor of sacred rhetoric and homiletics at Andover Theological Seminary, of which he was president from 1860 to 1879, when his failing health forced him to resign. He died on the 13th of October 1890 at Bar Harbor, Maine. His Theory of Preaching (1881) and English

1 Eliakim Phelps afterwards lived in Stratford, Herkimer county, New York, where his house was "possessed" and was long a place of curious interest to students of "spiritualism."
PHPELS, E. J.—PHENACETIN

**Style in Public Discourse** (1883) became standard textbooks: and personally he was a brilliant preacher. He married in 1842 Elizabeth Stuart (1824-1892), eldest daughter of Moses Stuart, then president of Andover; she was the author of the popular story **Sunnyside** (1851) and other books. In 1854 he married her sister, who died only eighteen months later; and in 1858 he married Mary A. Johnson, of Boston.

With Professors E. A. Park and D. L. Furber he edited **Hymns and Choirs** (1860), and with Professor Park and Lowell Mason **The Sabbath Hymn Book** (1859). The **Still Hour** (1859), a summary of a series of sermons on prayer, is a devotional classic. His other works are: **The New Birth** (1867), portraying conversion, (in some instances) as a gradual change; **Sabbath Hours** (1874); **Studies of the Old Testament** (1875); **Men and Books** (1882); **My Portfolio** (1882); **Miscellaneous Note Book** (1890).

See Austin Phelps: A Memoir (New York, 1891), by his daughter, Elizabeth Stuart Phelps-Ward.

**PHPELS, EDWARD JOHN** (1822-1900), American lawyer and diplomat, was born on the 11th of July 1822 at Middlebury, Vermont. He graduated from Middlebury College in 1840, was a schoolmaster for a year in Virginia, and was admitted to the bar in 1843. He began practice at Middlebury, but in 1845 removed to Burlington, Vermont. From 1851 to 1853 he was second comptroller of the United States Treasury, and then practised law in New York City until 1857, when he returned to Burlington. Becoming a Democrat after the Whig party had ceased to exist, he was debarred from a political career in his own state, where his party was in the minority, but he served in a constitutional convention in 1874, and in 1880 was the Democratic candidate for governor of his state. He was one of the founders of the American Bar Association, and was its president in 1880-1881. From 1881 until his death he was Kent Professor of Law in Yale University. He was minister to Great Britain from 1885 to 1889, and in 1893 served as senior counsel for the United States before the international tribunal at Paris to adjust the Bering Sea controversy. His closing argument, requiring eleven days for its delivery, was an exhaustive review of the case. Phelps lectured on medical jurisprudence at the university of Vermont in 1881-1883, and on constitutional law at Boston University in 1882-1883, and delivered numerous addresses, among them that on "The United States Supreme Court and the Sovereignty of the People" at the centennial celebration of the Federal Judiciary in 1890 and an oration at the dedication of the Bennington Battle Monument, unveiled in 1891 at the centennial of Vermont's admission to the Union. He was a liberal political propagandist, opposing the anti-silver movement before 1860, the free-silver movement in 1866, when he supported the Republican presidential ticket, and after 1868 becoming an ardent "anti-expansionist." He died at New Haven, Connecticut, on the 9th of March 1900.

**PHPELS, SAMUEL** (1804-1878), English actor and manager, was born at Devonport on the 13th of February 1804. He was early thrown upon his own resources, and worked in various newspaper offices. Shortly after his marriage in 1826 to Sarah Cooper (d. 1867), he accepted a theatrical engagement in the York circuit at eighteen shillings a week, and afterwards appeared in south of England towns in prominent tragic rôles, attracting sufficient attention to be spoken of as a rival to Kean. He made his first London appearance on the 28th of August 1837 at Shylock at the Haymarket. After a short season there he was with Macready for about six months at Covent Garden, the Haymarket and Drury Lane successively. In 1834 he became co-leisseur of Sadler's Wells Theatre with Thomas L. Greenwood and Mrs Mary Amelia Warner (1804-1854). Greenwood supplied the business capacity, Phelps the theatrical manager, and Mrs Warner leading lady. In this position Phelps remained for twenty years, during which time he raised the Sadler's Wells house to an important position, and himself appeared in a very extensive and varied repertory. Thirty-four of Shakespeare's plays were presented there under his direction, with great educational effect, both on public and players. In 1861 Greenwood retired from the partnership, and Phelps, unable to cope with the business of management, retired from it in the following year. For the next fifteen years he acted under various managements, achieving considerable success in some of Halliday's dramatic versions of Scott's novels, such as The Fortunes of Nigel and Ivanhoe. His last appearance was in 1878 as Wolsey in Henry VIII., and he died on the 6th of November 1878. He was a sound and capable actor, rather than one of any marked genius; and, in spite of his predilection for tragedy, was most successful in such characters of comedy as called for dry humour. Perhaps Sir Pertinax Macsycophant in Charles Macklin's The Man of the World was his finest impersonation. He published an annotated edition of Shakespeare's plays (2 vols., 1852-1854).

**PHYPEAUX,** a French family of Blésois. Its two principal branches were those of the signeurs of Herbuft, La Vrillière and Saint Florentin, and of the counts of Pontchartrain and Maurepas. Raimond Phypeaux, seigneur of Herbuft and La Vrillière (d. 1629), was treasurer of the Épargne in 1599, and became secretary of state in 1621. His son Louis succeeded him in this latter office, and died in 1681. Balthazar Phypeaux, marquis de Châteauneuf (d. 1700), and Louis, marquis de La Vrillière (d. 1725), respectively son and grandson of Louis, were also secretaries of state. Louis Phypeaux (1705-1777), count of Saint Florentin and afterwards duke of La Vrillière (1770), succeeded his father as secretary of state; became minister of the king's household in 1749, a minister of state in 1751, and discharged the functions of minister of foreign affairs on the disgrace of Choiseul (1770). He incurred great unpopularity by his abuse of lettres de cachet, and had to resign in 1775. Raimond Balthazar Phypeaux, seigneur du Verger, a member of the La Vrillière branch, was sent as ambassador to Savoy in 1700, where he discovered the intrigues of the Duke of Savoy, Victor Amadeus II., against France; and when war was declared he was kept a close prisoner by the duke (1703-1704). At the time of his death (1713) he was governor-general in the West Indies. The branch of Pontchartrain-Maurepas was founded by Paul Phypeaux (1560-1621), brother of the first-mentioned Raimond; he became secretary of state in 1610.

**PHENACETIN.** C₈H₄O₃C₂H₄-NHCOCH₃ (para-acetaminophenol), a drug prepared by acetylation para-phenetidin, or by heating para-acetylamino phenol and potassium ethyl sulphate with alcoholic soda to 150° C. Para-phenetidin is prepared by treating the sodium salt of para-nitrophenol with ethyl iodide, and reducing the nitrophenetol to para-phenetidin or aminophenol. The yield may be doubled by diazotizing para-phenetidin, coupling with phenol, chlorylating and reducing: 

\[ \text{EtO-C}_2\text{H}_4\text{NH} \rightarrow \text{EtO-C}_2\text{H}_4\text{N-OH} \rightarrow \text{EtO-C}_2\text{H}_4\text{N-C}_2\text{H}_5\text{OH} \rightarrow \text{EtO-C}_2\text{H}_4\text{N-C}_2\text{H}_5\text{OEt} \rightarrow \text{EtO-C}_2\text{H}_4\text{NH} \]

It crystallizes from water in colourless plates, melting at 153° C. It is soluble in about 70 parts of hot and in about 1400 parts of cold water.

Several compounds related to phenacetin have been introduced into medicine. Triphenin is propylphenetidin; lactophenin is lactylphenetidin; pyrardin is para-ethoxyphenyl succinimide, EtO-C₂H₄-NCOC₂H₃; salophen or saliphenin is salicylphenetidin; amygadophenin is mandelylphenetidin. In addition, several other derivatives have been suggested which have a greater solubility than phenacetin, e.g. phacin, which is the sodium salt of phenacetin sulphonic acid, apollis and citrophen (citrophenin), which are citric acid derivatives of para-phenetidin, &c.

Phenacetin is contained both in the British and United States pharmacopoeia, in the latter under the name of acethophenin. The dose is 5 to 10 gms. given in cachets or in suspension. When the drug is carelessly made it may contain impurities, producing considerable irritation of the kidneys. The therapeutic action of phenacetin consists in a sedative action on the sensory tracts of the spinal cord, and a depressant action on the heart, where it
tends to paralyse the action of the cardiac muscle. Upon the body, heat exercises a marked effect, decreasing the action of the heat-producing centre as well as increasing the dissipation of heat, and thus causing a marked fall in temperature. In toxic doses the blood becomes dark and blackish from the formation of methaemoglobin, and the urine is changed in colour from the passage of altered blood. The chief therapeutic use of phenacitin is as an antineuralgic, and it is of service in migraine, rheumatism of the sub-acute type, intercostal neuralgia and locomotor ataxia.

PHENACITE, a mineral consisting of beryllium orthosilicate, BeSiO₄, occasionally used as a gem-stone. It occurs as isolated crystals, which are rhombohedral with parallel-faced hemihedris, and are either lenticular or prismatic in habit: the lenticular habit is determined by the development of faces of several obtuse rhombohedral and the absence of prism faces (the accompanying figure is a plan of such a crystal viewed along the triad, or principal, axis). There is no cleavage, and the fracture is conchoidal. The hardness is high, being 7½–8, the specific gravity 3.95. The crystals sometimes colourless and transparent, but more often they are greyish or yellowish and only translucent; occasionally they are pale rose-red. In general appearance the mineral is not unlike quartz, for which indeed it had been mistaken; on this account it was named, by N. Nordenskjöld in 1833, from Gr. φήνα (a deceiver).

Phenacite has long been known from the emerald and chrysoberyl mine on the Takovaya stream, near Ekaterinburg in the Urals, where large crystals occur in mica-schist. It is also found with topaz and amazon-stone in the granite of the Ilmen mountains in the southern Urals and of the Pike’s Peak region in Colorado. Large crystals of prismatic habit have more recently been found in a felspar quarry at Kragerø in Norway. Framont near Schirmeck in Alsace is another well-known locality. Still larger crystals, measuring 12 in. in diameter and weighing 28 lb, have been found at Greenwood in Maine, but these are pseudomorphs of quartz after phenacite.

For gem purposes the stone is cut in the brilliant form, of which there are two fine examples, weighing 43 and 34 carats, in the British Museum. The indices of refraction (ω = 1.6540, ε = 1.6527) are higher than those of quartz, beryl or topaz; a faceted phenacite is consequently rather brilliant and may sometimes be mistaken for diamond. (L. J. S.)

PHENACODUS, one of the earliest and most primitive of the ungulate mammals, typifying the family Phenacondodontidae and the sub-order Condylarthra. The typical Phenacondus primaevus, of the Lower or Wasatch Eocene of North America, was a relatively small ungulate, of slight build, with straight limbs each terminating in five complete toes, and walking in the digitigrade fashion of the modern tapir. The middle toe was the largest, and the weight of the body was mainly supported on this and the two adjoining digits, which appear to have been encased in hoofs, thus forming a primitive type common in perissodactyle and certain extinct groups of ungulates. The skull was small, with proportionately minute brain; and the arched back, strong lumbar vertebrae, long and powerful tail, and comparatively feeble fore-quarters all proclaim kinship with the primitive creodont Carnivora (see CREODONTA), from which Phenacondus and its allies, and through them the more typical Ungulata, are probably derived. All the bones of the limbs are separate, and those of the carpus and tarsus do not alternate; that is to say, each one in the upper row is placed immediately above the corresponding one in the row below. The full series of forty-four teeth was developed; and the upper molars were short-crowned, or brachydont, with six low cones, two internal, two intermediate and two external, so that they were of the typical primitive bunodont structure. In habits the animal was cursorial and herbivorous, or possibly carnivorous. In the Puerco, or Lowest Eocene of North America the place of the above species was taken by Euprotopoidea primaevus, an animal only half the size of Phenacondus primaevus, with the terminal joints of the limbs intermediate between hoofs and claws, and the first and fifth toes taking their full share in the support of the weight of the body. These two genera may be regarded as forming the earliest stages in the evolution of the horse, coming below Hyracotherium (see EQUIDAE). As ancestors of the Artiodactyle section of the Ungulata, we may look to forms more or less closely related to the North American Lower Eocene genera Mioclaenus and Pantolestes, respectively typifying the families Mioclaenidae and Panto- lestidae. They were five-toed, bunodont Condylartha, with a decided approximation to the perissodactyle type in the structure of the feet. A third type of Condylartha from the North American Lower Eocene is represented by the family Menisoceroidea, including the genera Menisoceras and Myracops. These, it is suggested, may have been related to the ancestral Hyracocidae. Teeth and jaws probably referable to the Condylartha have been obtained in European early Tertiary formations. All Ungulata probably originated from Condylartha.

See H. F. Osborn, Skeleton of Phenacondus primaevus; comparison with Euprotopoidea, Bull. Amer. Mus. x. 159. (R. L.*)

PHENACINE, C_6H_5O, a hydrocarbon isomeric with anthracene, with which it occurs in the fraction of the coal tar distillate boiling between 270°–400° C. It may be separated from the anthracene oil by repeated fractional distillation, followed by fractional crystallization from alcohol (anthracene being the less soluble), and finally purified by oxidizing any residual anthracene with potassium bichromate and sulphuric acid (R. Anschütz and G. Schultz, Ann., 1879, 196, p. 35); or the two hydrocarbons may be separated by carbon bisulphide, in which anthracene is insoluble. It is formed when the vapours of tolulene, stilbene, dibenzyl, ortho-dityol, or coumarone and benzene are passed through a red-hot tube; by distilling morphine with zinc dust; and, with anthracene, by the action of sodium on ortho-brombenzyl bromide (C. L. Jackson and J. F. Whiting, J. Chem. Soc., 1886, p. 391). It crystallizes in colourless plates or needles, which melt at 90° C. Its solutions in alcohol and ether have a faint blue fluorescence. When heated to 250° C. with red phosphorus and hydriodic acid it gives a hydride C_4H_4. It is nitrated by nitric acid and sulphuric acid. With picric acid it forms a sparingly soluble picrate, which melts at 145° C. On the condition of phenacine in alcoholic solution see R. Behrend, Zeit. phys. Chem., 1892, 9, p. 405; 10, p. 265. Chromic acid oxidizes phenacine, first to phenacine-oquinone, and then to diphenic acid, HOOC.C_6H_4.CO.H.

Phenacine-oquinone, [C_6H_5]CO.O, crystallizes in orange needles which melt at 198° C. It possesses the characteristic properties of a diketone, forming crystalline derivatives with sodium bisulphite and a dioxime with hydroxylamine. It is non-volatile in steam, and is odourless. Sulphuric acid reduces it to the corresponding dihydroxy compound. It combines with ortho-diamines, in the presence of acetic acid.

On the constitution of phenacine see Chemistry: § Organic.

PHENAZINE (Azophenylene), C_6H_5N_2O, in organic chemistry, the parent substance of many dyestuffs, e.g., the eudrhines, toluylen red, indulines and safranines. It is a dibenzopara- diazine having the formula given below. It may be obtained by distilling barium azobenzaoate (A. Claus, Ber., 1873, 6, p. 723); by passing aniline vapour over lead oxide, or by the oxidation of dihydrophenazine, which is prepared by heating pyrocatechin with orthophenylene diamine (C. Ris, Ber., 1886, 19, p. 2266). It is also formed when ortho-amidophenylamine is distilled over lead peroxide (O. Fischer and E. Hepp). It crystallizes in yellow needles which melt at 171° C., and are only sparingly soluble in alcohol. Sulphuric acid dissolves it, forming a deep-red solution. The more complex phenazines, such as the naphthophenazines, naphthazinophenzones and naphthothiazolines, may be prepared by condensing ortho-diamines with ortho-quinones (O. Hinsberg, Ann., 1887, 237, p. 340); by the oxidation of an ortho-diamine in the presence of a naphthol (O. Witt) and by
the decomposition of ortho-anilido-(toluidido- &c.)azo compounds with dilute acids. If alkyl or aryl-ortho-diamines be used azonium bases are obtained. These azines are mostly yellow in colour, distinctly aromatic, and are stable to oxidants. They add on alkyl iodides readily, forming alkyl azonium salts.

By the entrance of amino or hydroxyl groups into the molecule dyestuffs are formed. The mono-amino derivatives or curdolines are obtained when the arylamines are condensed with ortho-aminoazo compounds; by condensing quinone dichloride or para-aminodimethylamine with monamines containing a free para position, or by oxidizing ortho-hydroxyaminophenylamines (R. Nietzsche, *Ber.*, 1895, 28, p. 2976; O. Fischer, ibid., 1896, 29, p. 1574). They are yellowish-red solids, which behave as weak bases, their salts undergoing hydrolytic dissociation in aqueous solution. When heated with concentrated hydrochloric acid the amino group is replaced by the hydroxyl group and the phenolic curdolines are produced.

The yellowish-red aminophenazone is the parent substance of the important dyestuff toluidone red or dimethylaminotoluphenazine. It is obtained by the oxidation of orthophenylene diamine with ferric chloride; when a mixture of para-aminodimethylamine and meta-toluenediamine is oxidized in the cold, toluidone blue, an indigene, being formed as an intermediate product and passing into the red when boiled; and also by the oxidation of dimethyl paraphenylene diamine with metatoluenylamine, it crystallizes in orange-red needles and its alcoholic solution fluoresces strongly. It dyed silk and mordanted cotton a fine scarlet. It is known commercially as *neutral red*. For the phenazone salts see *SAFRINGE*.

Phenazone is an isomer of phenazine, to which it bears the same relation that phenanthrene bears to anthracene. It is formed by reducing diortho-dinitrophenyl with sodium amalgam and methyl alcohol, or by heating diphenylene-ortho-dihydrazine with hydrochloric acid. It has two crystalline modifications, one at 156° C. Potassium permanganate oxidizes it to pyridazine tetracarboxylic acid.

### PHENOLPHTHALEIN

In organic chemistry, a compound derived from phthalpheneone, or diphenyl phthalide (formula I.), the anhydride of triphenyl-carbino-ortho-carboxylic acid, which is obtained by condensing phthalyl chloride with benzene in the presence of aluminium chloride. The phenalines are obtained by the entrance of hydroxyl or amino groups into the two phenyl residues, and are prepared by condensing phenols with phthalic anhydride, phenol itself giving rise to phenolphthalein (formula II.) together with a small quantity of fluoran (formula III.), whilst resorcin under similar conditions yields fluoresecin (q.v.). The phthalic acids on reduction yield phthalinches, which are derivatives of triphenylmethane carboxylic acid; these reduction products are colourless and on the addition of the test liquid, phenolphthalein itself gives phenolphthalein (formula IV.).

Dehydrating agents usually convert the phenolphthalines into antquinoine derivatives.

Phenolphthalein is obtained when phenol and phthalic anhydride are heated with concentrated sulphuric acid. It crystallizes in colourless prisms and is nearly insoluble in water, but dissolves in dilute alcoholic and aqueous solutions, and is soluble in most organic solvents. It is very stable in dilute solution but is slowly decomposed in concentrated alkali. Its yellow colour is not at all depigmented by carbon dioxide; this property of the anhydride makes it a suitable indicator for alkali solutions to a considerable extent (see H. Meyer, *Monaist.*, 1899, 20, p. 337; R. Meyer, *Ber.*, 1903, 36, p. 2949; A. G. Perkin and Green, *Jour. Chem. Soc.*, 1904, p. 398).

On fusion with caustic alkali, phenolphthalein yields benzoic acid and monobromoanil. Phthalhydrazone, which shows that in the original condensation the phthalic acid residue has taken the para position to the hydroxyl groups of the phenol. It is a product of the condensation of the phthalic acid residue in the ortho position to the hydroxyl groups of the phenol.

Anhydride formation also takes place between these hydroxyl groups. It dissolves in concentrated sulphuric acid with a yellowish-green fluorescence. The rhodamines, which are closely related to the phthalines, are formed by the condensation of the alkyl metanalysis with phenolphthalein in the presence of sulphuric acid. Their salts are fine red dyes.

### PHENOMENON

(Gr. φαινειν, a thing seen, from φαίνειν, to appear), in ordinary language a thing, process, event, &c., observed by the senses. Thus the rising of the sun, a thunderstorm, an earthquake are natural "phenomena." From this springs the incorrect colloquial sense, something out of the common, an event which especially strikes the attention; hence such phrases as "phenomenal" activity. In Greek philosophy phenomena are the changing objects of the senses as opposed to essences (φασίν, φασίδα) which are one and permanent, and are therefore regarded as being more real, the objects of reason rather than of senses which are "bad witnesses." In modern philosophy the phenomenon is neither the "thing-in-itself," nor the noumenon (q.v.) or object of pure thought, but the thing-in-itself as it appears to the mind in sensation (see especially *KANT* and *METAPHYSICS*). In this sense the subjective character is of prime importance. Among derivative terms are "Phenomenology," "Phenomenological," and "phenomenological" (1) the doctrine that there can be no knowledge except by phenomena, i.e. sense-given data, or (2) the doctrine that all known things are phenomena, i.e. that there are no "things-in-themselves." "Phenomenology" is the science of phenomena: every special science has a special section in which its particular phenomena are described. The term was first used in English in the 3rd edition of the *Ency. Brit.* in the article "Philosophy" by J. Robison. Kant has a special use of the term for that part of the *Metaphysic of Nature* which considers motion and rest as predicates of a judgment about things.

### PHERECRATES

Greek poet of the Old Attic Comedy, was a contemporary of Cratinus, Crates and Aristophanes. At first an actor, he seems to have gained a prize for a play in 438 B.C. The only other ascertained date in his life is 426, when he produced his play *The Wild Men*. Like Crates, when he imitated, he abandoned personal satire for more natural themes, although in some of the fragments of his plays we find him attacking Alcibiades and others. He was especially famed for his inventive imagination, and the elegance and purity of his diction are attested by the epithet ἀριστωκάραιos (most Attic) applied to him by Atheneaus and the sophist Phrynichus. He was the inventor of a new metre, called after him Pherecratean, which frequently occurs in the choruses of Greek tragedies and in Horace.

A considerable number of fragments from his 16 (or 13) plays have been preserved, collected in T. Kock, *Comiconorum Aliturum Fragmenta*, 1. (1880), and A. Meinecke, *Posticonorum Codicorum Fragmenta* (1855).

### PHERECYDES OF LEROS

Greek mythographer, fl. c. 454 B.C. He is probably identical with Pherecydes of Athens, although the two are distinguished by Suidas (also by L. Lipsius, *Quaestiones logographiae*, 1886). He seems to have been born in the island of Leros, and to have been called an Athenian because he spent the greater part of his life and wrote his great work there. Of his treatises, *On Leros*, *On Iphigenia*, *On the Festivals of Dionysus*, nothing remains; but numerous fragments of his anecdotes of the gods and heroes, variously called *Topia*, *Topia*, *Teraeogonos*, *Aproeomos*, in ten books, written in the Ionic dialect, have been preserved (see C. W. Müller's *Frag. hist. graec.,* vol. i. pp. xxxiv., 70). He modified the legends, not with a view to rationalizing them, but rather to adjust them to popular beliefs. He cannot, therefore, be classed with Hecataeus, whose method was far more scientific.

### PHERECYDES OF SYROS

Greek philosopher (or rather philosophical theologian), flourished during the 6th century B.C. He was sometimes reckoned one of the Seven Wise Men, and is said to have been the teacher of Pythagoras. With the possible
PHIGALIA, or PHIGALEIA (Φιγάλεια; mod. Pavlínos), an ancient Greek city in the south-west angle of Arcadia, situated on an elevated rocky site, among some of the highest mountains in the Peloponnese—the most conspicuous being Mt Cotylium and Mt Elasmos; the identification of the latter is uncertain.

In 659 B.C., Phigalia was taken by the Laccedemonians, but soon after recovered its independence by the assistance of the Corinthians. A great part of the city wall, built in fine Helionic masonry, partly polygonal and partly isodomic, and a large square central fortress with a circular projecting tower are the only remains now traceable—at least without the aid of excavation. The walls, once nearly 2 m. in circuit, are strongly placed on rocks, which slope down to the little river Neda.

One very important monument still exists in a fairly perfect state; it is a temple dedicated to Apollo Epieirus (the Preserver), built, not at Phigalia itself, but at Bassae, 5 or 6 m. away, on the slope of Mt Cotylium; it commemorates the aid rendered by Apollo in stopping a plague which in the 5th century B.C. was devastating Phigalia. This temple is mentioned by Pausanias (viii. 41) as being (next to that of Tegea) the finest in the Peloponnese, "from the beauty of its stone and the symmetry of its proportions." It was designed by Ictinus, who with Callicrates, was [first architect of the Parthenon at Athens. Though visited by Chandler, Dodwell, Gell, and other English travellers, the temple was neither explored nor measured till 1811-1812, when C. R. Cockerell and some other archaeologists spent several months in making excavations there. After nearly fifty years' delay, Professor Cockerell published the results of these labours, as well as of his previous work at Aegina, in *Temples of Aegina and Bassae* (1860), one of the most careful and beautifully illustrated archaeological works produced. The labours of Cockerell and his companions were richly rewarded; not only were sufficient remains of the architectural features discovered to show clearly the whole design, but the internal sculptural frieze of the cella was found almost perfect. This and other fragments of its sculpture are now in the British Museum. The colonnade of the temple has been recently restored by the Greek authorities.

The figure shows the plan of the temple, which is of the Doric order, but with remarkable details of its cella unlike that of any other known temple. It stands on an elevated and partly artificial plateau, which commands an extensive view of the oak-clad mountains of Arcadia, reaching away to the blue waters of the Messenian Gulf. Unlike other Doric temples, which usually stand east and west, this is placed north and south; but it has a side entrance on the east. It is hexastyle, with fifteen columns on its flanks; thirty-four out of the thirty-eight columns of the peristyle are still standing, with the greater part of their architrave, but the rest of the entablature and pediments have fallen, together with the greater part of the internal columns of the cella. It will be seen from the plan that it was not very splendidly placed, apparently without symmetry, as regards the interior, through they are set regularly opposite the voids in the peristyle.

With the exception of one at the south end, which is Corinthian, the internal columns are of the Ionic order, and are engaged with the cella, forming a series of recesses, which may have been designed to contain statues. Another peculiarity of this interior is that the columns reach to the top of the cella in one order, not in two ranges of columns, one over the other, as was usual in Doric temples. The inner columns carried an Ionic entablature, of which the frieze now in the British Museum formed a part. The pediments and metopes of the peristyle appear to have contained no sculpture, but the metopes within the peristyle on the exterior of the cella had sculptured subjects; only a few fragments of these were, however, discovered. The position occupied by the temple and its relation to the temple of Apollo at Bassae, are of great interest, particularly as the cella wall, set back about 8 ft., has been covered by Cockerell, who, with almost incredible labour, separated from the wall the small pieces of the sculptured frieze, all of which are of white marble. The roo-tiles, specially noticed by Pausanias, are remarkable for their size, workmanship, and the beauty of the Parian marble of which they are made. They measure 2 ft. 1 in. by 3 ft. 6 in. and are fitted together in the most careful and ingenious manner. Unlike those of the Parthenon and the temple of Aegina, the *epidi* or "joint-tiles" are worked out of the same piece of marble as the flat ones, for the sake of more perfect fitting and greater security against wet. The gain in the cost of materials was more than balanced by the architectural value of the building. The sculptural members were found by Cockerell, but they were too much faded for the colours to be distinguished. The designs are the usual Greek patterns—the frut, the honeysuckle, and the egg and dart.

The capture of this temple by the Persians, as being designed to decorate one of the finest buildings in the Peloponnese in the latter half of the 5th century B.C., is one of the most important events in the history of art. The temple, now in the British Museum, is complete; it is nearly 10 ft. long by 2 ft. high, carved in relief on twenty-three slabs of marble 4½ to 5 in. thick. The subjects are the battle of the Lapithae and the Centaurs, and that between the Amazons and the Greeks, the
PHILADELPHIA, the Greek name (1) of a city in Palestine in the land of Ammon (see AMMONITES), and (2) of a city so-called in honour of Attalus II. of Pergamum, the modern Al-Shehr (q.v.).

PHILADELPHIA, the third city in population in the United States, the chief city of Pennsylvania, and a port of entry, co-extensive with Philadelphia county, extending W. from the Delaware river beyond the Schuylkill River, and from below the confluence of the Delaware and Schuylkill rivers N.E. about 23 m. along the Delaware river and Poquessing Creek. Independence Hall, which is a few squares east by south of the city hall, is in 39° 30' 57.5" N. and 75° 8' 54.75" W. The port is about 102 m. from the Atlantic Ocean, and the city hall is 90 m. by rail S.S.W. of New York and 135 m. N.E. of Washington. The city has an area of 132.7 sq. m. At the southern extremity are lowlands protected by dikes from the tide; the business centre begins at a short distance from the lower town. From Broad Street about 1 mile west of the Schuylkill is generally rolling; and in the upper district the surface rises from the Delaware toward the north-west until in the extreme north-west is a picturesque district overlooking Wissahickon Creek from hills exceeding 400 ft. in height.

Population.—When the first United States census was taken, in 1790, Philadelphia was the second largest city in the Union, and had a population of 28,522. It held this rank until 1830, when it was exceeded in size by Baltimore as well as by New York. In 1830 it was smaller also than Boston; but in 1854 the Consolidation Act extended its boundaries so as to include all Philadelphia county and in 1860 the city had risen again to second rank. This rank it held until 1890 when, although its population had grown to 1,046,964, it was 50,000 less than that of Chicago. In 1900, with a population of 1,293,679, it was still farther behind both New York and Chicago. In 1900, of the total population, 998,357, or 77.18%, were native-born, as against only 63.5% native-born in New York and 65.43% native-born in Chicago. Of Philadelphia's native-born white population, however, 414,093, or 44.24%, were of foreign-born parentage. The foreign-born population included 98,427 born in Ireland, 71,319 born in Germany, 36,752 born in England, 28,951 born in Russia (largely Hebrews), 17,830 born in Italy, 8479 born in Scotland and 5154 born in Austria; and the coloured consisted of 62,613 negroes, 1165 Chinese, 234 Indians and 12 Japanese. In 1910 the population was 1,549,008.

Streets.—With the exception of a limited number of diagonal thoroughfares and of streets laid out in outlying districts in conformity with the natural contour of the ground the plan of Philadelphia is regular. The city is divided into sections by principal streets. High Street— is the principal thoroughfare east and west, Broad Street the principal thoroughfare north and south, and these streets intersect at right angles at City Hall Square in the business centre. The streets parallel with Broad are numbered from First or Front Street west from the Delaware River to Sixth-Third Street, taking the prefix " North " or " north " of Market Street and the prefix " South " or " south " of it; the streets parallel with Market are numbered mostly from trees and from the governors and -residences of Pennsylvania.

The wholesale district is centred at the east end of Market Street near the Delaware river. The best retail shops are farther west on the south side of Chestnut Street and on Market and Arch streets. Most of the leading banks and trust companies are on Chestnut Street and on Third Street between Chestnut and Arch streets. Several of the larger office buildings and the stations of the Pennsylvania and the Philadelphia & Reading railways are in the vicinity of the city hall; here too, are the Baldwin Locomotive Works. The large textile mills, the great coal and ore yards of the Cramp Ship-Yards are to the north-east along the Delaware, and in districts west of these are the leading manufactures of iron and steel. There are large sugar refineries in the south-eastern part of the city. Rittenhouse Square, a short distance south-west of the city hall, is the centre of the old aristocratic residential district, and the south side of Walnut Street between Fourteenth and Nineteenth streets is a fashionable parade. There are fine residences on North Broad Street and on some of the streets crossing it, and many beautiful villas in Roxborough. The new residential districts to the north-west, of suggested tenements, occupied largely by Italians, Jews and negroes, are along the alleys between the rivers and south of Market Street, often in the rear of some of the best of the older residences.

The principal structure is the city hall (or " Public Buildings") one of the largest buildings in the world in ground space (14 acres). It rises 548 ft. to the top of a colossal bronze statue (37 ft. high) of William Penn (by Alexander Calder) surmounting the tower. It accommodates the state and county courts as well as the municipal and county offices. The foundation stone was laid in August 1872. On its first floor is Joseph A. Ball's statue of Washington, which was erected in front of Independence Hall in 1869. Above the Public Building are statues of General Washington, General and Governor of Pennsylvania, by McClellan and Reynolds, President McKinley, and Joseph Leidy and St. Gaudens' " Pilgrim." On all sides are great buildings: on the north the masonic temple (1868-1873); on the south the statey Betz Building; on the west the enormous Broad Street station of the Pennsylvania railway. The Pennsylvania Academy of Fine Arts and the Oddfellows' Temple are among other notable buildings in the vicinity. The post office, facing Ninth Street and extending from Market Street to Chestnut Street, was opened in 1884; in front is a seated statue of Benjamin Franklin, by John J. Boyle. The mint is at the corner of Sixteenth and Spring Garden streets. The custom-house, on Chestnut Street, was designed by William Strickland (1787-1854), in his day the leading American architect. It was modelled after the Parthenon of Athens, was built for the Second United States Bank, was completed in 1824, and was put to its present use in 1845. Other prominent buildings of
which Strickland was the architect and the stock exchange, St Paul's Protestant Episcopal Church, St Stephen's Church, the almshouse and the United States Naval Asylum. The main building of Girard College (on Girard Avenue, between North 10th and North 25th streets), of which Thomas Ustick Walker (1804-1887), a pupil of Strickland’s, was the architect, is one of the finest specimens of pure Greek architecture in America. Near the Schuylkill river, in West Philadelphia, are the buildings of the university of Pennsylvania. Its free museum of science and art, at South 23rd and Spruce, on the opposite side of the river, was built from the designs of Walter Cope, Frank Miles Day and Wilson Eyre, and its north-western part was first opened in 1890. Tall steel-frame structures, of which the Betz Building, completed in 1893, was the first, have become numerous. The Roman Catholic Cathedral of St Peter and St Paul, east of Logan Square, was begun in 1846 and was eighteen years in building. The Arch Street Methodist Episcopal Church is one of the most handsome churches in the city. The South Memorial Church of the Advocate (1897), on North 18th and Diamond streets, is a reproduction on a smaller scale of Amiens Cathedral in France.

Perhaps the most famous historical monument in the United States is Independence Hall, on Chestnut Street between Fifth and Sixth streets, designed for the state house by Andrew Hamilton (c. 1676-1741), speaker of the assembly, and was used for that purpose until 1790. The foundations were laid in 1731 and the main building was ready for occupancy in 1735, although the entire building was not completed until 1751. The steeple was taken down in 1774 but was restored by Strickland in 1828, and further restorations of the building to its original condition were effected later. In the early room on the first floor of this building the second Continental Congress met on the 10th of May 1775, George Washington was chosen commander-in-chief of the Continental army on the 15th of June 1775, and the Declaration of Independence was adopted on the 4th of July 1776. The room contains much of the furniture of those days, and on its walls are portraits of forty-five of the fifty-six signers of the Declaration and a portrait of Washington by Peale. At the head of the staircase is the famous Liberty bell, which bears the inscription “Proclaim liberty throughout all the land unto all the inhabitants thereof” and is supposed (without adequate evidence) to have been the first bell to announce the adoption of the Declaration of Independence. It was cast in England in 1752, was cracked soon after it was brought to America, was recast with more copper in Philadelphia, and was cracked again in 1835 while being tolled in memory of Chief Justice John Marshall, and on the 22nd of February 1843 this crack was so increased as nearly to destroy its sound. On the second floor is the original of the charter which William Penn granted to the city in 1701 and the painting of Penn’s treaty with the Indians by Benjamin West. The building has been set apart by the city, which purchased it from the state in 1816, as a museum of historical relics. On the north-west corner of Independence Square is old Congress hall, in which Congress sat from 1790 to 1800, and in which Washington was inaugurated in 1793 and Adams in 1797. At the north-east corner is the old city-hall, now the second floor of which the Supreme Court of the United States sat from 1790 to 1800. At a short distance east of Independence Square in Carpenters’ Hall, in which the first continental congress assembled on the 5th of September 1774 and in which the national convention in 1787 framed the present constitution of the United States; the building was also the headquarters of the Pennsylvania committee of correspondence, the basement was used as a magazine for ammunition during the War of Independence, and from 1791 to 1797 the whole of it was occupied by the First United States Bank. The Carpenters’ Company (established in 1724) erected the building in 1770, and since 1857 has preserved it wholly for its historic associations. On Arch Street near the Delaware is preserved as a national monument the house in which Betsy Ross, in 1777, made what has been called the first United States flag, in accordance with the resolution of Congress of the 14th of June. Not far from this house is Christ Church (Protestant Episcopal), the first colonial edifice designed mainly by Dr John Kearsley (1684-1772). The cornerstone was laid in 1727, but the steeple, in part designed by Benjamin Franklin and containing a famous chime of eight bells, was not completed until 1754. The interior was restored to its ancient character in 1882, the pews of Washington and Franklin are preserved, and a set of communion plate presented to the church by Queen Anne in 1708 is used on great occasions. In the churchyard are the graves of Benjamin Franklin, Robert Morris, Brigadier-General John Forbes, John Penn, Peyton Randolph, Francis Hopkinson and Benjamin Rush. St Peter’s, the second Protestant Episcopal Church in the city, has a massive tower and a simple spire; within are the original pews. In the south-east part of the city near the Delaware is the ivy-clad Old Swedes’ Church, built of brick in 1698-1700. The house which William Penn built about 1683 for his daughter Letitia was removed to Fairmount Park and rebuilt in 1835. In Germantown (c.), a suburb which was annexed in 1834, are several other historic buildings.

The dominant feature of the domestic architecture is the long row houses, after the style of the old Flemish dwellings, with ledges of red (“Philadelphia”) pressed brick with white marble steps and trimmings, and with white or green shutters, each intended for one family.

Parks.—Fairmount Park extends along both banks of the Schuylkill for about 5 m. and from the confluence of the Schuylkill and Wissahickon Creeks to the confluence of the Schuylkill and Wissahickon through a romantic glen for 6 m. Its area is about 3,418 acres. Five acres of an estate belonging to Robert Morris during the War of Independence and known as “Fair Mount,” or “The Hills,” were purchased by the city in 1793, and were added to the park purposes by act of the legislature in 1812, and from this beginning the park grew to its present dimensions by purchases and gifts. The principal buildings in the park are: the McPherson mansion, once the property of Benedict Arnold (1746-1801), acquired by the city in 1798; the Peters (or Belmont) Mansion, built in 1745 and much frequented by the notables of the Revolutionary and early national period; the birth-place of David Rittenhouse, the astronomer; and a mausoleum of the German Pietists, both on the banks of Wissahickon Creek; the 25th street speaker’s corner, built in 1857, and used for public purposes by act of the legislature in 1864, and which was removed in 1897 to the park grounds; the Columbia Avenue entrance to the park and near the East Park Reservoir are the children’s playground and playground, endowed by the will of Mrs Sarah A. Smith (d. 1893). At the Green Street entrance is an imposing monument to Washington, designed by Rudolph Siemering and erected by the Society of the Cincinnati in 1896-1897, with a bronze equestrian statue. The Smith Memorial entrance, white granite with bronze statues, was erected in memory of the officers of the Civil War. The park also contains a monument to Lincoln by Randolph Rogers; an equestrian statue of Grant by Daniel Chester French and Edward C. Potter; an equestrian statue of Major-General James Gordon Meade by Alexander Milne Calder; an equestrian statue of Joan of Arc by Emmanuel Fremiet; an heroic bust of James A. Garfield by Augustus St Gaudens; statues of Columbus, Humboldt, Schiller and Goethe; a Tam O’Shanter statue of Cuchullin by Sir George Frampton; a Wounded Lion by William Wolf’s (“Wounded Lioness” (at the entrance to the Zoological Gardens); Albert Wolf’s “‘Lion Fighter’; Auguste Nicolas Cain’s ‘Lioness bringing a Wild Boar to her Cubs’; Edward Kemper’s “Cow in the Fields” (Old Farm, Monroe County); a number of smaller monuments, and a number of smaller statues of animals and birds.

In the downtown district, Franklin, Washington, Rittenhouse and Logan squares, equidistant from the city hall, have been reserved for public parks from the earliest days. The Rittenhouse Square is the square of Conon and Serpent” of A. L. Barye. In Clarence H. Clark Park, West Philadelphia, is Frank Edwin Elwell’s group “Dickens and Little Nell.” In Broad and Spring Garden streets opposite the Baldwin Locomotive Works is Herbert Adolph Dreyfus’s statue of Franklin (1765-1832), founder of the works. Close to the bank of the Delaware, some distance N.N.E. of the city-hall, is the small Penn Treaty Park with a monument to mark the site of the great elm tree under which Penn and Logan met in 1682 to confer with the Indians in 1683. In the south-west part of the city, along the Schuylkill, is Bartram’s botanical garden (27 acres), which the city...

1 Many of the statues and other works of art in Fairmount and other parks are the gift of the Fairmount Park Art Association (1871; reorganized in 1888 and 1906).
added to its park system in 1891; in it is the stone house, with ivy-covered walls, which the famous botanist built with his own hands.

Through the efforts of the City Park Association, organized in 1888, a number of outlying parks, connecting parkways and small parks and squares have been added to the park system. Among these are League Island Park (300 acres), opposite the United States navy yard on League Island; Penny Pack Creek Park (about 1200 acres), extending 63 m. along Penny Pack Creek, in the northwest; Washington Square Park (40 acres), opened in 1827, on the eastern border; Fairmount Parkway, 300 ft. wide on a direct line southeast from Fairmount Park to Logan Square and somewhat narrower from Logan Square to the city-hall; and Torresdale Parkway (300 ft. wide, 45 ft. deep) between Torresdale andEffectuate Avenue.

Among the more notable and interesting objects of the larger numbers of birds since it acquired, in 1846, the collection of the du Rivoli numbered more than 12,000 specimens; several smaller bird collections are also on view. A notable collection of shells and fossils and the "types" of Leidy, Cope, Say and other naturalists, and a library. It is composed of the "collections" biological and microscopical (1868), entomological (1876), botanical (1876), mineralogical and geological (1877) and ornithological (1891). It has published a Journal since 1871 and its Proceedings since 1841, and periodicals on entomology, conchology and ornithology. To a few young men and women it gives training in scientific investigation without charge. The Pennsylvania Historical Society, organized in 1824, has a valuable collection of historical material, including the papers of the Pennsylvania family and the Charlemagne Tower collection of American colonial armor. At the present time are housed in the Philadelphia, the Keystone, the Merion (at Haverford), and the Germantown (at Manheim).

dated the opening of the present "model school," in 1753, was chartered as a college and academy in 1755, and became the University of Pennsylvania by act of the state legislature passed in 1791. The university occupied the site of the present University of Pennsylvania, and in 1824, was removed to the grounds near the western bank of the Schuylkill.

The foundation of the present free public school system was laid in 1818 by an act of the legislature which constituted the city and county of Philadelphia "a common school district" and empowered the board of Trustees of the Philadelphia Museum and Library Company to establish a "model school" in 1753, was chartered as a college and academy in 1755, and became the university of Pennsylvania by act of the state legislature passed in 1791. The university occupied the site of the present University of Pennsylvania, and in 1824, was removed to the grounds near the western bank of the Schuylkill.

household science and library economy departments; a School of industrial arts; two manual training schools; about one hundred night schools (attended mainly by adults); several special schools for habitual truants or insubordinate and disorderly children; and a number of classes in the mechanics of the steam engine and other machines. In 1900 district high schools were planned as a part of the public school system. The city has also many private high schools and academies.

At the head of the university of Pennsylvania and the Central High School for boys the collegiate institutions are La Salle College (Roman Catholic; opened in 1867) and the Temple University (non-sectarian; chartered in 1885 as Temple College after four years of technical instruction). In the present century the philosophical departments were designed especially for self-supporting men and women and was founded by Russell Hermann Conwell (b. 1842), a lawyer and journalist, who entered the Baptist ministry in 1879, was pastor of the Grace Baptist Temple in Philadelphia until 1891, and was a member of the Grace Baptist Temple in Philadelphia until 1891, and was a member of the Temple University, which was in 1891 established as the Temple University. It was the first president of the Temple College, which was in 1891 established as the Temple University. It was the first president of Temple College, which was in 1891 established as the Temple University.

In 1891 the University of Pennsylvania was chartered as the University of Pennsylvania by an act of the legislature of the state, which was passed in 1878; and in 1897 the Philadelphia Dental College, one of the best known dental schools in the country, joined the university. In 1893 a trust fund left by Hyman Gratz was used to found the Gratz College for the purpose of teaching Hebrew and English in the study of the Hebrew language, and Jewish history, literature, and religion; the college is under the control of the Kaal Kidosch Mikwe Israel of Philadelphia. Bryn Mawr College (1894), one of the leading institutions for women in the United States, was founded by the Quakers, and has an enrollment of about 800 students.

The University of Pennsylvania has a large library, the largest of the free arts; and since 1876 has maintained a museum, the largest of its kind in the country. The university has a number of departments, including a department of art and art history, a department of science, a department of engineering, and a department of music. The university has also a number of libraries, including the library of the university, the library of the museum, and the library of the art school.

The city of Philadelphia has a number of institutions for the education of boys and girls, including the University of Pennsylvania, the Temple University, and the Gratz College. The University of Pennsylvania has a number of libraries, including the library of the university, the library of the museum, and the library of the art school. The university has also a number of museums, including the museum of the university, the museum of the art school, and the museum of the art school.

PHILADELPHIA

built-up portion of the city have a single track of electric railway (overhead trolley), and most of the wider ones, except Broad Street, which has none, have a double track. A subway line has been opened for a short distance under Market Street, and other subway lines are in progress. Both thetwo systems, embracing in 1910 a total of 624.21 m., is operated by the Philadelphia Rapid Transit Company. Several inter-urban electric lines afford cheap service to neighbouring towns and cities. The extensive railway system under the control of the Pennsylvania rail- way company, which has its offices at Philadelphia, connects the city with transportation facilities north to New York, south to Baltimore, Washington and the south, west to the bituminous coalfields of Pennsylvania, the grain fields of the Middle West, and to Pittsburgh, Cleveland, and other points. The Delaware and Pennsylvania railway connects the city with the great anthracite coal region, and both the Philadelphia & Reading and the Pennsylvania control a line to Atlantic City. The Schuylkill is navigable for small craft to the city. Steamers are drawn 26 ft. to the oil refineries at Point Breeze, 3 m. from the mouth; from Point Breeze to the head of navigation the channel depth varies from 14 to 22 ft. The Delaware river is navigable to Trenton, New Jersey, about 30 m. above the upper end of Philadelphia, and although in its natural condition this river was only 17 ft. deep at low water in its shallowest part below the port it had increased by 1869 and 1899 to 26 ft. (except in the shoal stretches), and a depth of 8 ft. was maintained for ten years. Steamships ply regularly between Philadelphia and several European ports, in the West Indies, and ports of the United States.

The port extends from the Pennsylvania railway terminal at Greenwich and South Penn station to the west end of Delaware and the Reading terminal at Port Richmond, a distance of about 8 m. and there are minor harbour facilities on the Schuylkill. The natural facilities, together with the improvements that have been made, were long offset by an inefficient port administration under an antiquated law of 1863, which permitted the city to be governed only by a board of private control; but in 1907 the old board of port wardens was abolished and in its place was created a municipal department of wharves, docks and piers. Under the opening of the Erie Canal, in 1825, Philadelphia was the emporium of the United States; it was then displaced by New York. Some years later Philadelphia lost its lucrative China trade, and its decline in commercial importance continued until 1884, when it was 30 m. when its imports were only 20 m. (as against 80 m. for the average of the business of the port in 1883), and a large part of its business was done by private trade. Steamships ply regularly between Philadelphia and several European ports, in the West Indies, and ports of the United States.

Manufactures.—Philadelphia has always been one of the foremost manufacturing centres in the United States, and in 1905 it was outstripped only by New York and Chicago. The total value of its output was $5,198,812 in 1900, and $59,348,078 in 1905. The leading industries have been the weaving of cotton, worsted and silk, among the cities of the country in 1905 in refining sugar and molasses ($37,182,594; 13.4% of the total output) and in the manufacture of carpets and rugs ($25,532,510; 4% of the total of the country); third in the manufacture of woolen goods ($12,329,881; 8.6% of the total of the country); and, lastly in the manufacture of clothing ($12,154,822; 5.1% of the total of the country). The leading manufacturing establishments in order of importance are: the Philadelphia Cotton Manufacturing Company (16.6% of the total of the country); the tomatoes (16% of the total of the country); the manufacture of glass (16.8% of the total of the country); and in dyeing and finishing textiles ($4,371,006; 8.6% of the total of the country); and third in the manufacture of clothing ($31,011,882; 5.1% of the total of the country). Other large industries are the manufacture of foundry and machine-shop products, cotton goods, malt liquors, iron and steel, chemicals, cigars and cigarettes, soap, confectionery, furniture, boots, shoes, and paint and paper products the value of Philadelphia's manufactured products is greater than that of any other city in the country.
PHILADELPHIA

are: public safety, public works, receiver of taxes, city treasurer, city controller, law, education, charities and corrections, supplies, wharves, docks and ferries, civil service commission and sinking fund commission (composed of the mayor, the city controller and a commissioner elected by a majority vote of the city council). Members of the select council are elected for three years—one-third each year; members of the common council for two years—one half each year; and the receiver of taxes, the city treasurer, the city controller, and the city solicitor, who is the head of the purchase department for 1909, constitute a superintendent appointed by the director of the department with the approval of the select council. The department of education is administered by a board appointed (at large) by the judges of the common pleas.

The assessed value of taxable property in the city increased from $153,369,048 in 1856 to $356,667,834 in 1880, to $880,915,265 in 1900, and to $1,479,680,990 in 1910. Philadelphia's industrial expansion, which began in 1879, exceeded $18,851,442 in 1856 to $14,640,477 in 1880, to $30,628,246 in 1900, and to $48,012,630 in 1909. The principal items of expenditure in 1909 were: for public schools $8,224,218; for the bureau of water, $8,827,200; for streets and highways, $4,218,266; for police, $3,816,525; and for protection against fire, $1,873,720. The receipts for the same year were $44,372,927, of which $15,851,422 were from the property tax (municipal and state), and $4,396,124 were from the water tax. The city's indebtedness—of which $37,737,163 was for school bonds and $8,173,840 was for a debt exceeding 7% of the assessed value of its taxable property—is in 1879 the state legislature passed an act to prevent the city from living beyond its income, and as a consequence of these restrictions the city's financial position has been greatly improved. Loans held by the sinking fund, was reduced by the beginning of 1895 to $33,139,665. The great expense of installing the new filter plant, developing the park system, and making other improvements has, however, caused it to grow again; at the beginning of 1910 the total funded debt was $85,483,820 and the total funded debt was $95,480,900 as of 1998.

History.—The patent granted to William Penn for the territory embraced within the present commonwealth of Pennsylvania was signed by Charles II. on the 4th of March 1681 and Penn agreed that "a quantity of land or ground plot should be laid out for a large town or city in the most convenient place upon the river for health and navigation," and that every purchaser of 500 acres in the county shall be allowed a lot of 10 acres in the town or city, "if the place will allow it." In September Penn appointed William Crispin, Nathaniel Allen and John Bezan a commission to proceed to the new province and lay out the city, directing them to select a site on the Delaware where "it is most navigable, high, dry and healthy; that is where most ships can best ride, of deepest draught of water, if possible to load or unload at the bank or key side without boating or lightering of it." Crispin, a kinsman of the proprietor, died on the voyage out, but William Hieage had been named a fourth commissioner some time after the appointment of the others and the three survivors arrived in the province toward the close of the year. They had been preceded by Penn's cousin, Captain William Markham, as deputy-governor, and were soon followed by the surveyor-general, Thomas Holme, and by a Swaensgon or Swaenwasson, who selected the north of the Schuylkill not later than 1643 and the site now selected by the commissioners was held by three brothers of the Swaensson family, these brothers agreed to take in exchange land in what is now known as Northern Liberties, and as early as July 1682 Holme, according to modified instructions from Penn for making the lots smaller than originally intended, laid out the city extending from the Delaware river on the east to the Schuylkill river on the west, a distance of about 2 m., and from Vine Street on the north to Cedar (now South) Street on the south, a distance of about 1 m. Penn landed at New Castle on the Delaware on the 27th of October 1682 and two days later came up as far as Upland, now Chester, 13 m. south of Philadelphia, but when he came to his newly founded city is not known. He is known, however, to have presided at a meeting of the provincial council held here on the 10th of March 1683, and from that time Philadelphia was the capital of Pennsylvania until 1799, when Lancaster became the capital. During nearly the whole of this period it was also the most important city commercially, politically and socially in the colonies. Quaker influence was strong in the city, especially up to the beginning of the 19th century; and it was predominant in Philadelphia long after it had given way before the Scotch-Irish in the rest of Pennsylvania. But even in Philadelphia the academy (later the university of Pennsylvania) soon came under the control of the Protestant Episcopal Church. The first Continental Congress met in Carpenter's Hall on the 5th of September 1774; the second in the old state house (Independence Hall) on the 10th of May 1775; and throughout the War of Independence, except from the 26th of September 1777 to the 18th of June 1778, when it was in possession of the British, Philadelphia was the virtual capital of the colonies; it was a brilliant social city, especially during the British possession. The national convention which framed the present constitution of the United States sat in Philadelphia in 1787, and from 1790 to 1800 the city was the national capital. Here Benjamin Franklin and David Rittenhouse made their great contributions to science, and here Washington delivered his farewell address to the people of the United States. Here, in July and August 1786, the clerical and lay delegates from the Protestant Episcopal Churches in the United States met and formally organized the Protestant Episcopal Church in the United States. Here the first bank in the United States—the Bank of North America—was opened in 1782, and here the first mint for the coinage of the money of the United States was established in 1792. The city was visited with an epidemic of yellow fever in 1793 and again in 1798; and in 1832 nearly 1000 inhabitants died of Asiatic cholera.

The original boundaries remained unchanged for 172 years, but the adjoining territory as it became populated was erected into incorporated districts in the following order: Southwark (1762), Northern Liberties (1771), Moyamensing (1812), Spring Garden (1813), Kensington (1820), Penn (1844), Richmond (1847), West Philadelphia (1851) and Belmont (1853). In 1854 all these districts, together with the boroughs of Germantown, Frankford, Manayunk, White Hall, Bridesburg and Aramingo, and the townships of Passyunk, Blockley, Kingsessing, Roxborough, Germantown, Bristol, Oxford, Lower Dublin, Moreland, Byberry, Delaware and Penn was abolished and the boundaries of Philadelphia were extended to the county lines by a single act of the state legislature. The consolidation was in part the outcome of a demand for efficiency in preserving order. There had been occasional outbreaks of disorder: on the 17th of May 1838 an anti-abolition mob had burned Pennsylvania Hall, which had been dedicated three days before to the cause of abolition, temperance and equality; in May 1843 anti-Catholic rioters had burned St Michael's and St Augustine's churches, and minor riots had occurred in 1835, 1842 and 1843. Philadelphia was from the first strongly anti-slavery in sentiment, and it was here in December 1833 that the American Anti-Slavery Society was organized, and in 1856, on the anniversary of the battle of Bunker Hill, that the first national convention of the Republican party met. During the Civil War the arsenal and the Southwark navy yard were busy manufacturing material for the Federal armies, the city was crowded with wounded soldiers, and here in 1864 was held the great sanitary fair for the benefit of the United States sanitary commission, an organization for the relief and care of wounded and sick soldiers. In 1876, the centennial year of American independence, a great exhibition of the industries of all nations was held in Fairmount Park from the 10th of May to the 10th of November, and about fifty buildings were erected for the purpose. In October 1882 the city celebrated the bi-centennial of the landing of William Penn, and in October 1908 the 225th anniversary of its foundation.

1 Lord Howe, who had been in command of the British, embarked for England on the 24th of May, and on the 18th of this month was held for his farewell entertainment the famous Michilacara, a feast of gaiety with a tournament somewhat like those common in the age of chivalry, which was in large part planned by Captain John Andr

If the debt of a city already exceeded the 7% limit it could be increased only by permission of the legislature.
PHILADELPHIANS—PHILARET 373

PHILADELPHIANS, a sect of religious mystics, founded in London in the latter part of the 17th century. In 1652 Dr John Pordage (1607–1681), rector of Bradfield, Berkshire, gathered together a few followers of Jakob Boehme, the chief of whom was Jane Lead or Leade (née Ward; 1623–1704). Pordage was ejected from his living by the Triers in 1655, but was restored in 1660. Mrs Leade had been from girlhood of a mystical temperament, and experienced phantasms which she recorded in a diary entitled A Fountain of Gardens, beginning in 1670, in which year the Philadelphian society was definitely organized. She drew up for it "The Laws of Paradise," which show that the enterprise was designed "to advance the Kingdom of God by improving the life, teaching the loftiest morality, and enforcing the duty of universal brotherhood, peace and love." Its members had a strong faith in what they called the "Divine Secrets," the wonders of God and nature, the profound spiritual experiences of regeneration and soul-resurrection, and the second Advent. In 1693 some of Mrs Leade's writings were translated into Dutch, and by this means and her acquaintance with Francis Lee (1661–1716), an Oxford scholar who taught medicine at Leiden and became her son-in-law, a connexion was opened up with Germany and Holland. In 1703 the Philadelphians drew up their confession, but they made no further progress and soon declined. The Holland branch withdrew, and the English government forbade the society to meet. For many years, however, a considerable number of people regarded Mrs Leade's visions, which were published in a long series of writings, as proofs of her divine calling. In her later years she had a severe struggle with poverty, which was relieved by a pension granted by Baron Kniphausen.

PHILA, an islet in the Nile above the First Cataract, of great beauty and interest, but since the completion of the Assuan dam in 1902 submerged except for a few months yearly during High Nile (July to October), when the water is allowed to run freely through the sluices of the Assuan dam. Philae is the nearest island to the point of entrance of the river. The ruins of Philae, which were towed by the river, are a short distance south of the cataract. It marks also the end of the cataract region. Below it the channel is broad and straight with rocky granite islands to the west. The name in Egyptian was Pilak, "the angle (?) island?" the Arabs call it Anas el Wagu, after the hero of a romantic tale in the Arabian Nights. Ancient graffiti abound in all this district, and on Bigha, a larger island adjoining Philae, there was a temple as early as the reign of Tethmosis III. The name of Amasis II. (370–353 B.C.) is said to have been found at Philae, and it is possible that there were still older buildings which have been swallowed up in later constructions. About 350 B.C. Nektanebo, the last of the native kings of Egypt, built a temple to Isis, most of which was destroyed by floods. Ptolemy Philadelphus reconstructed some of this work and began a large temple which Ptolemy Euergetes I. completed, but the decoration carried on under later kings, the Ptolemies and Caesar, was never finished. The temple of Isis was the chief sanctuary of the Dodecachoeneus, the portion of Lower Nubia generally held by the Ptolemies and Romans. The little island won great favour as a religious resort, not only for the Egyptians and the Ethiopians and others who frequented the border district and the market of Assuan, but also for Greek and Roman visitors. One temple or chapel after another sprang up upon it dedicated to various gods, including the Nubian Mandulis. Ergameus (Arkame), king of Ethiopia, shared with the Ptolemies in the building. Besides

the temple of Isis with its birth-temple in the first court, there were smaller temples or shrines of Arsinoeus, Mandulis, Imuthes, Hathor, Harendotes (a form of Horus) and Augustus (in the Roman style), besides unnamed ones. There were also monumental gateways, and the island was protected by a stone quay all round with the necessary staircases, &c., and a Nilometer. The most beautiful of all the buildings is an unfinished kiosk enclosed by Tranjan, well known under the name of "Pharaoh's Bed." Graffiti of pilgrims to the shrine of Isis are dated as late as the end of the 5th century A.D. The decree of Theodosius (A.D. 378) which suppressed pagan worship in the empire was of little effect in the extreme south. In A.D. 453 Maximinus, the general of the emperor Marcian, after inflicting a severe defeat on the Nobatae and Blemmyes who were settled in Lower Nubia, and thence raided Upper Egypt, made a treaty in terms which included permission for these heathen tribes to visit the temple and even to borrow the image of Isis on certain occasions. It was not till the reign of Justinian, A.D. 527–565, that the temple of Philae was finally closed, and the idols taken to Constantinople. Remains of Christian churches were disclosed by the thorough exploration carried out in 1895–1896 in view of the Barrage scheme, under the direction of Captain Lyons. The accumulations of rubbish on the island were cleared away and the walls and foundations of the stone buildings were all repaired and strengthened before the dam was completed. The annual flooding now appears to be actually beneficial to the stonework, by removing the disintegrating salts and incrustations. The tops of most of the buildings and the whole nucleus of the temple of Isis to the floor remained all these years above the water level until the dam was raised another 26 ft.—a work begun in 1907—when the temples were entirely submerged except during July–October. But the beauty of the island and its ruins and palm trees, the joy of travellers and artists, is almost gone.

See H. G. Lyons, A Report on the Island and Temples of Philae ( Cairo, 1896), with numerous plans and photographs; a second report, A Report on the Temples of Philae (1908), deals with the condition of the ruins as affected by the immersions occasioned by the filling of the Assuan dam; Baedeker's Egypt; and on the effects of the submersion, &c., reports in Annales du service des antiquités, vols. iv. v. (F. Ll. G.)

PHILARET [Theodore Nikitch Romanov] (?1553–1633), patriarch of Moscow, was the second son of the boyar Nikita Romanovitch. During the reign of his first cousin Theodore I. (1584–1598), Theodore Romanov distinguished himself both as a soldier and a diplomatist, fighting against the Swedes in 1599, and conducting negotiations with the ambassadors of the czar, Peter I. In 1602–1603. On the death of the childless tsar, he was the popular candidate for the vacant throne; but he acquiesced in the election of Boris Godunov, and shared the disgrace of his too-powerful family three years later, when Boris compelled both him and his wife, Xenia Chestovaya, to take monastic vows under the names of Philaret and Martha respectively. Philaret was kept in the strictest confinement in the Antoniev monastery, where he was exposed to every conceivable indignity; but when the pseudo-Demetrius overthrew the Godunovs he released Philaret and made him metropolitan of Rostov (1605). In 1609 Philaret fell into the hands of pseudo-Demetrius II., who named him patriarch of all Russia, though his jurisdiction only extended over the very limited area which acknowledged the impostor. From 1610 to 1618 he was a prisoner in the hands of the Polish king, Sigismund III., whom he refused to acknowledge as tsar of Muscovy on being sent on an embassy to the Polish camp in 1610. He was released on the conclusion of the truce of Deulino (Feb. 13, 1610), and on the 2nd of June was canonically enthroned patriarch of Moscow. Henceforth, till his death, the established government of Muscovy was a duchy. From 1619 to 1633 there were two actual sovereigns, Tsar Michael and his father, the most holy Patriarch Philaret. Theoretically they were co-regents, but Philaret frequently transacted affairs of state without consulting the tsar. He replenished the treasury by a more equitable and rational system of assessing and collecting the taxes. His most important
domestic measure was the chaining of the peasantry to the soil, a measure directed against the ever increasing migration of the down-trodenners to the towns, where they became free-booters instead of tax-payers. The taxation of the tsar’s slyzakhrievi, i.e., military tenants, was a first step towards the proportional taxation of the hitherto privileged classes. 

Philatelic zeal for the purity of orthodoxy sometimes led him into excesses: but he encouraged the publication of theological works, formed the nucleus of the subsequently famous Patriarchal Library, and commanded that every archbishop should establish a seminary for the clergy, himself setting the example. Another great service rendered by Philat to his country was the reorganization of the Muscovite army with the help of foreign officers. His death in October 1633 put an end to the Russo-Polish War (1632–33), withdrawing the strongest prop from an executive feeble enough even when supported by all the weight of his authority.

See R. N. Bain, The First Romanovs (London, 1903); S. M. Solovev, History of Russia (Russe), vol. ii, St Petersburg, 1895, &c. (R. N. B.)

PHILATELY—PHILEMON (Gr. φιλάτης, loving, and ἀρετής, free of tax), the study and collection of postage-stamps and other marks of prepayment issued by post-offices. The fancy for collecting postage-stamps began a short time after the issue of the first British penny and two-penny stamps in 1840 (see Post and Postal Service). Dr Gray, an official of the British Museum, began collecting them soon after their appearance, and an advertisement in an issue of The Times of 1841 asks for gifts of cancelled stamps for a young lady. In 1842 the new hobby was ridiculed in Punch. It was not until about 1860, however, that stamp collecting began to be systematically carried on with full regard to such minutiae as the different kinds of paper, water-marks, perforation, shade of colour and distinctive outline. About 1862 a teacher in Paris directed that foreign stamps should be collected and pasted upon the pages of his pupils’ atlases and geographical records by countries, and this may have been the first form of the systematic classification of stamps in a collection. Of existing collections the oldest were begun between 1853 and 1860, by which year French collectors had assumed especial prominence. Professional dealers, like the appearance, and in 1861 philatelic literature, now of vast extent, was inaugurated by the publication in Strasbourg of a catalogue of stamps issued up to that time. The Paris collectors were the first to classify stamps, measure them by the gauge, note the water-marks and separate the distinct issues of each country. Collecting with due regard to the relationship of different issues is called platting. The first English catalogue was issued in 1862, followed in December of the same year by The Stamp Collector’s Review and Monthly Advertiser, published in Liverpool, the first philatelic periodical, the second, The Stamp Collector’s Magazine, appearing in 1863. In 1863 also appeared Le Timbre-Poste, a Brussels journal. Up to 1920 over 800 philatelic periodicals had appeared.

Although small bodies of enthusiasts had banded together in England, France and the United States for the study and collection of postage-stamps as early as 1865, it was not until 1868, when the first great club, the Philatelic Society of London, still the most important in the world, was founded. Other societies in Great Britain are the Junior Philatelic of London, and those of Birmingham, Manchester, Edinburgh and Leith. The leading society in America is the American Philatelic Association; in France the Société française de timbres; in Germany the Internationaler Philatelisten-Verein. More than 400 such organizations are now in existence, the majority of them in the United States and Germany. At a philatelic congress, held in London in 1910, the formation of a universal union of philatelic societies to encourage unnecessary or speculative issues was considered.

Not only the stamps themselves were collected, but “entires,” i.e., postcards, envelopes with the stamps still adhering, &c. Marks of prepayment at last became so numerous that, about 1850, specialists began to appear, who restricted their collections to the stamps of some particular country or continent, or to postcards or newspaper-wrappers alone. The most extensive and valuable stamp collection in the world, that of Baron P. von Ferrary of Paris, was begun about 1863. This collection, which cost its owner at least £50,000, contains a cancelled and an uncancelled specimen of each stamp. The next greatest collection is that bequeathed to the British Museum in 1891 by T. K. Tapping, M.P., now in the British Museum. Among other important collections may be mentioned those in the German Postal Museum in Berlin, of King George V. of England, W. B. Avery, H. J. Duveen and the earl of Crawford. The largest sum realized for an entire collection was £27,500, which was paid for that of M. P. Castle, consisting of European stamps only. The value of a stamp depends partly upon its age, but much more upon its rarity, which again is dependent upon the number of the particular stamps originally issued. Most stamps have a quoted value, but some possess a conventional value only, such as those of which only one or two specimens are known to exist; for instance, the one-cent stamp of the 1865 issue of British Guiana (one known copy); the Italian 15 centesimi stamp of 1865 converted by an overprint into 20 centesimi (one copy); the Chinese Good Year triangular, printed by mistake on paper intended for stamps of other colonies (four copies); and the 2-cent stamps of the earliest issue of British Guiana (ten copies). The best known of the very rare stamps are the 1d. and 2d. “Post-Office” Mauritius, for which higher prices have been paid than for any other stamps, although 23 copies are known to exist out of the 1000 issued. For a fine specimen of these Mauritius stamps £2000 has been offered. Two of them have been sold for £2400. Philatelic exhibitions such as those held in London in 1890 and 1897 and in Manchester in 1909 have proved popular.

"Reprints" are reappearances, taken from the original plates, of obsolete stamps, and have a much smaller value than specimens of the original issue. Forgeries of the rarer stamps are common but are easily detected. Modern postage-stamp albums are often beautiful specimens of the printer’s art, reproductions of every known stamp being given in the original colours.

PHILEMON (c. 361–263 B.C.), Greek poet of the New Comedy, was born at Soli in Cilicia, or at Syracuse. He settled at Athens early in life, and his first play was produced in 330. He was a contemporary and rival of Menander, whom he frequently vanquished in poetical contests. Posterity reversed the verdict and attributed Philomen’s successes to unfair influence. He made a journey to the east, and resided at the court of Ptolemy, king of Egypt, for some time. Plutarch (De Cohibenda Ira, 9) relates that on his journey he was driven by a storm to Cyrene, and fell into the hands of the king’s Magas, whom he had formerly satirized. Magas treated him with contempt, and finally dismissed him with a present of toys. Various accounts of his death are given; a violent outburst of laughter, excess of joy at a dramatic victory, or a peaceful end while engaged in composing his last work (Apuleius, Florius, 16; Lucian, Macrob. 25; Plutarch, Ap Sens, p. 725). Of the ninety-seven plays which he is said to have composed, the titles of fifty-seven and considerable fragments have been preserved. Some of these may have been the work of his son, the younger Philumen, who is said to have composed fifty-four comedies. The Merchant and The Treasure of Philomen were the originals respectively of the Mercator and Trinummus of Plautus. The fragments preserved by Stobaeus, Athenaeus and other writers contain much wit and good sense. Quintillian (Inst. x. 1, 72)
PHILEMON, EPISTLE TO—PHILETAS

PHILEM. Onesimus, a slave, had robbed Philemon (vv. 11, 18-19) and run away from his master Philemon, a prosperous and influential Christian citizen of Colossae (Col. iv. 9), either offence rendering him liable to be crucified. Voluntarily or accidentally, he came across Paul, who won him over to the Christian faith. In the few tactful and charming lines of this brief note, the apostle sends him back to his master with a plea for kindly treatment. After greeting Philemon and his wife, with Archippus (possibly their son) and the Christians who met for worship at Philemon’s house (vv. 1-2), Paul rejoices over (vv. 4-7) his correspondent’s character; it encourages him to make an appeal on behalf of the unworthy Onesimus (8-21), now returning (Col. iv. 9) along with Tychicus to Colossae, as a penitent and sincere Christian, in order to resume his place in the household. With a line or two of personal detail (22-25) the note closes.

Rome would be a more natural rendezvous for fugitive slaves than Caesarea (Hilgenfeld and others), and it is probable that Paul wrote this note, with Philippians and Colossians, from the metropolis. As Laodicea is close to Colossae it does not follow, even if Archippus be held to have belonged to the former town (as Lightfoot argues from Col. iv. 13-17), that Philemon’s residence must have been there also (so A. Maier, Thielsch, Wieseler, &c.). Paul cannot have converted Philemon at Colossae (Col. ii. 1), but elsewhere, possibly at Ephesus; yet Philemon may have been on a visit to Ephesus, for, even were the Ephesian Onesimus of Ignatius (Eph. ii.) the Onesimus to which Paul refers in the Colossian epistle, he lived there. No adequate reason has been shown for suspecting that the note is interpolated at any point. The association of Timotheus with Paul (v. 1) does not involve any official tinge, which would justify the deletion of και Τιμόθεος στῷ δηλήθη μου in that verse, and of ἡμῶν in vv. 1-2 (so Holtzmann), and Haußman’s suspicions of the allusion to Paul as a prisoner and of v. 2 are equally arbitrary. The construction in vv. 5-6 is difficult, but it yields to exegetical treatment (cf. especially Haußmann’s note) and does not involve the interpolation of matter by the later redactor of Colossians and Ephesians (Holtzmann, Haußmann & Brückner, Reihenfolge d. paul. Briefe, 200 seq.).

The brevity of the note and its lack of doctrinal significance prevented it from gaining frequent quotation in the early Christian literature, but it appears in Marcion’s canon as well as in the Muratorian, whilst Tertullian mentions, and Origen expressly quotes it (during the 19th century, the hesitancy about Colossians led to the rejection of Philemon by some critics as a pseudonymous little pamphlet on the slave question—an aberration of literary criticism (reproduced in Eucy. Bibl., 3693 seq.) which needs simply to be chronicled. It is interesting to observe that, apart from the letter of commendation for Phoebe (Rom. xvi.), this is the only letter in the New Testament addressed, even in part, to a woman, unless the second epistle of John be taken as meant for an individual.

BIBLIOGRAPHY. — In addition to most commentaries on Colossians and to Dr. M. R. Vincent’s edition of Philippians, compare special exegetical studies by R. Rollock (Geneva, 1602), G. C. Storr (1781), J. K. 1. Demme, Erklärung d. Philomones-Briefes (1844); H. A. Peterson, Ad fidem versionum ... cum eorum textu orig. grecce (Berlin, 1844); M. Rothe, Pauli ad Philom. epistolae interpretatio historico-critica (1853), and Geschichte der altchristlichen Wissenschaft (1873), pp. 428 sqq. Besides the essays of J. G. C. Klotzsch, De occasione et indeo epistolae ad Philom. (1792); D. H. Wildsche, De vi dictiorum et sermonis elegantis in epistola ad Philom. (1799), and Der Brief an d. Philemon (1829), a survey of criticism is furnished by Dr. J. H. Bernard in Hastings’ Dictionary of the Bible, iv. 832-834, and a good exposition may be found in Z. Weber’s Der Brief an d. Philemon, ein Vorbild für die christl. Behandlung sozialer Fragen (1896), as well as in Dr. A. H. Drysdale’s devotional commentary (London, 1906).

PHILEMON and BAUCIS, the hero and heroine of a beautiful story told by Ovid (Metam. viii. 690-705), the scene of which is laid in Phrygia. Zeus, accompanied by his impecunious earth-ling Demyth, tired and weary, they sought shelter for the night, but all shut their doors against them except an aged couple living in a humble cottage, who afforded them hospitality. Before their departure the gods revealed themselves, and bade their hosts follow them to the top of a mountain, to escape the punishment destined to fall on the rest of the inhabitants. The country was overwhelmed by a flood; the cottage, which alone remained standing, was changed into a magnificent temple. The gods appointed Philemon and Baucis priest and priestess, and granted their prayer that they might die together. After many years they were changed into trees—Philemon into an oak, Baucis into a lime. The story, which emphasizes the sacred duty of hospitality, is probably of local Phrygian origin, put together from two widely circulatcd legends of the visits of gods to men, and of the preservation of certain individuals from the flood as the reward of piety. It lingers in the account (Acts vii.) of the healing of the lame man by Paul at Lystra, the inhabitants of which identified Paul and Barnabas with Zeus and Hermes, “come down in the likeness of men.”

Similar stories are given in J. Grimm, Deutsche Mythologie (Engl. trans., 1883, ii. 580, and iii. 38).

PHILES, MANUEL (c. 1275-1345), of Ephesus, Byzantine poet. At an early age he removed to Constantinople, where he was the pupil of Georgius Pachymeres, in whose honour he composed a memorial poem. Philes appears to have travelled extensively, and his writings contain much information concerning the imperial court and distinguished Byzantines. Having offended one of the emperors by indirect remarks published in a chronography, he was thrown into prison and only released after an abject apology. Philes is the counterpart of Theodorus Prodomus in the time of the Comneni; his character, as shown in his poems, is that of a beggar poet, always pleading poverty, and ready to descend to the grossest flattery to obtain the favourable notice of the great. With one unimportant exception, his productions are in verse, the greater part in dodecasyllabic iambic trimeters, the remainder in the fifteen-syllable "political" measure.

Philes was the author of poems on a great variety of subjects; on the characteristics of animals, chiefly based upon Aelian and Oppian, a didactic poem of some 2000 lines, dedicated to Michael Palaeologus; on the elephant; on plants; a necrological poem, probably written on the death of the sons of Constantine II; a panegyric on John Cantacuzene, in the form of a dialogue; a conversation between a man and his soul; on ecclesiastical subjects, such as church festivals, Christian beliefs, the saints and fathers of the church; on works of art, perhaps the most valuable of all his pieces, or for their beauty, on Byzantine iconography, since the writer had before him the works he describes, and also the most successful from a literary point of view; occasional poems, many of which are simply beggar letters in verse.

Editions: the natural history poems in F. Lehms and F. Dümmer, Poetae baciicci et didactici (Ditototy, 1846); Manuelis Philae Carmina inedita, ed. A. Martini (1900); Manuelis Philae Carmina ed. E. Miller (1855-1857). See also C. Krumbacher, Geschichte der byzantinischen Literatur (1897).

PHILETAS of Cos, Alexandrian poet and critic, flourished in the second half of the 4th century B.C. He was tutor to the son of Potommy I. of Egypt, and also taught Theocritus and the grammarians Zenodotus. His thinness made him an object of ridicule; according to the comic poets, he carried foxes in his shoes, and so polluted himself from being eaten alive. Oster’s study of Megarian dialectical subtleties is said to have shortened his life. His elegies, chiefly of an amatory nature and singing the praises of his mistress Battis (or Bittis), were much admired by the Romans. He is frequently mentioned by Ovid and Propertius, the latter of whom imitated him and preferred him to his rival Callimachus, whose superior mythological lore was more to the taste of the Alexandrian critics. Philetas was also the author of a vocabulary called Arastra, explaining the meanings of rare
and obscure words, including words peculiar to certain dialects; and of notes on Homer, severely criticized by Aristarchus.

Fragments edited by N. Bach (1828), and T. Bergk, Poetae lyrici Graeci; see also E. W. Maass, De tribus Philaeas carminibus (1895).

PHILIDOR, FRANÇOIS ANDRÉ DACAN (1726-1795).
French composer and chess-player, was born at Dreux, on the 7th of September 1726, of a musical family. The family name was Danican, but that of Philidor, added in the middle of the 17th century, eventually supplanted the older name. François André received a musical education as a member of the corps of pages attached to the orchestra of the king; and subsequently he earned his living by giving lessons and copying music. Much of his time was, however, devoted to chess, at which he soon became an expert. He spent many years in travelling on the Continent and in England, meeting and defeating the most noted players of the time, and is regarded as the strongest player and greatest theoretician of the 18th century. Returning to France in 1754, he resolved to devote himself seriously to musical composition, and after producing several works of minor importance brought out in Paris, in the year 1759, his successful light opera, Biais le Sauvietor, which was followed by a number of others, notably Le Soldat magicien (1760), Le Jardinier et son sieur (1761), Le Sorcier (1762), and Tom Jones (1764). He died in London on the 31st of August 1795.

PHILIP (Gr. ΦΙΛΙΠΠΟΣ, found of horses, from φιλεῖν, to love, and πτως, horse; Lat. Philippus, whence e.g. M. H. Ger. Philipp, Dutch Philip, and, with dropping of the final s, It. Filippo, Fr. Philippe, Ger. Philipp, Sp. Felipe), a masculine proper name, popularized among the Christian nations as having been that of one of the apostles of Christ. Notices of distinguished men who have borne this name are arranged below in the following order: (1) Biblically; (2) Kings of Macedonia, France, Germany and Spain; (3) other rulers.

PHILIP, one of the twelve apostles, mentioned fifth in all the lists (Matt. x. 23; Mark iii. 18; Luke vi. 14; Acts i. 13). He is a mere name in the Synoptists, but a figure of some prominence in the Fourth Gospel. There he is said to have been “of Bethsaida, the city of Andrew and Peter,” and to have received his call to follow Jesus at Bethany, having previously been, it would seem, a disciple of the Baptist (John i. 43, 44; cf. 28). Philip was at that time the means of bringing Nathanael to Jesus (John i. 45), and at a later date he, along with Andrew, carried the request of the inquiring Greeks to the Master (John xii. 22). Philip and Andrew alone are mentioned by name in connexion with the feeding of the five thousand (John vi. 5, 7), and Philip is also one of the few interlocutors in John xiv. Slight though these references are, all agree in presenting Philip as of an inquiring and calculating character, slow to take the initiative, but, when convinced of the path of duty, thoroughly loyal in following it. After the resurrection he was present at the election of Matthias as successor to Judas, but he does not appear again in the New Testament history; it is, however, implied that he still continued in Jerusalem after the outbreak of the first persecution.

Little reliance can be placed on the traditional accounts of Philip, owing to the evident confusion that had arisen between him and the evangelist of the same name, who appears in the book of Acts (see below). According to Polycrates, bishop of Ephesus, in his controversial letter written to Victor of Rome towards the end of the 2nd century (Ap. Euseb. H. E., ii. 31, v. 24), the graves of Philip “of the twelve apostles,” and of his two aged virgin daughters were in (the Phrygian) Hierapolis; a third daughter, “who had lived in the Holy Ghost,” was buried at Ephesus. With this may be compared the testimony of Clement of Alexandria, who incidentally (Strom. iii. 6) speaks of Philip as having begotten children and as having given daughters in marriage. On the other hand, Proclus, one of the interlocutors in the “Dialogue of Caius,” writing of somewhat later date than the letter of Polycrates, mentions (Ap. Euseb. H. E., iii. 31) “four prophetesses, the daughters of Philip at Hierapolis in Asia, whose tomb and that of their father are to be seen there,” where the mention of the

PHILIDOR—PHILIP (KINGS OF MACEDONIA)

daughters prophecying identifies the person meant with the Philip of Acts (cf. Acts xxii. 8). The reasons for setting aside this latter identification, and for holding that the Philip who lived at Hierapolis was the Apostle are clearly stated by Lightfoot, Colossians (2) note 3, p. 45 seq., and fresh confirmation of his view has recently been afforded by the discovery of an inscription at Hierapolis, showing that the church there was dedicated to the memory of the holy and glorious apostle and theologian Philip” (Ramsay, Cities and Bishops of Phrygia, vol. i., pt. ii. p. 552).

See also Conson, “Die Töchter des Philippus” in the Zeitschrift für die neuesten lichen Wissenschaft (1901), p. 289 seq. The other view, that the Philip of Hierapolis is the Philip of Acts, is taken by Zahn, “Die Berichtigung der Geschicht des Hierapolis” (1900), vi. 158 seq.

A later stage of the tradition regarding Philip appears in various late apocryphal writings which have been edited by Tischendorf in his Acta apostolorum apocrypha, and in his Apocryphae apocryphi. According to the Acta Philippi, a work belonging at the earliest to the close of the 4th century (see Zahn, op. cit. p. 18 sqq.), Philip, with Bartholomew and his own sister Mariamne, exercised a widespread missionary activity, preaching not only throughout Asia Minor, but also in Hellas the city of the Athenians, in Scythia, and in Gaul, &c. According to one account he died a natural death; according to another he was hanged or crucified, head downwards. An apocryphal gospel, which describes the progress of the soul through the next world, bears his name (Hennecke, Neuestenl. Apokryphen, 1904, p. 40 seq.).

Since the 6th century Philip has been commemorated in the West, along with St James the Less, on the 1st of May, their relics being deposited in the same church in Rome; in the Eastern Church Philip’s day is the 14th of November, and that of James the Less the 23rd of October.

PHILIP, “the angelizer,” is first mentioned in the Acts (v. 5) as one of “the seven” who were chosen to attend to certain temporal affairs of the church in Jerusalem in consequence of the murmurings of the Hellenists against the Hebrews. After the martyrdom of Stephen he went to “the city of Samaria,” where he preached with much success, Simon Magus being one of his converts. He afterwards instructed and baptized the Ethiopian eunuch on the road between Jerusalem and Gaza; next he “caught away” by the Spirit and “found at Azotus” (Ashdod), whence “passing through he preached in all the cities till he came to Caesarea” (Acts viii.). Here some years afterwards, according to Acts xxi. 8, 9, where he is described as “the evangelist” (a term found again in the New Testament only in Eph. iv. 11; 2 Tim. iv. 5), he entertained Paul and his companion on their way to Jerusalem; at that time “he had four daughters which did prophesy.” At a very early period he came to be confounded with the apostle Philip (see above); the confusion was all the more easy because, as an esteemed member of the apostolic company, he may readily have been described as an apostle in the wider sense of that word (see further Salmon, Intro. to the New Testament, 2nd ed., p. 313 seqq.). A late tradition describes him as settling at Tralles in Asia Minor, where he became the overseer or ruler of the church. “Philip the deacon” is commemorated on the 6th of June.

PHILIP I, king of Macedonia, a semi-legendary prince, son of Argeus, was, according to Herodotus (viii. 137-139) and Thucydides (ii. 100), the third of the Macedonian kings. In the texts of Dexippus and Eusebius he ranks sixth, Caranus, Coenus and Thurimus (or Turimmas) being there regarded as the predecessors of Perdiccas I., whom Herodotus and Thucydides regard as the first king of Macedonia. Eusebius and Dexippus assign to Philip I. a reign of 38 and 35 years respectively. There is, however, no real evidence for his existence.

PHILIP II (382-336 B.C.), king of Macedonia, the son of Amyntas II., and the Lycean Eurydice, reigned 359-336. At his birth the Macedonian kingdom, including the turbulent peoples of the hill-country behind, was very imperfectly consolidated. In 370 Amyntas died, and the troubled reign of
PHILIP (KINGS OF MACEDONIA)

Philip's eldest brother, Alexander II., was cut short in 368 by his assassination. His murderer, Ptolemy of Alorus, ruled as regent for the young Perdiccas, Amyntas' second son. In 367 Philip was delivered as hostage to the Thebans, then the leading power of Greece (by whom does not seem clear). During the three years he spent at Thebes the boy no doubt observed and learnt much. When he returned to Macedonia (364) Perdiccas had succeeded in getting rid of Ptolemy; but he fell in 360–359 before an onset of the hill tribes instigated by the queen-mother Eurydice, leaving only an infant son. Various pretenders sprang up and the kingdom fell into confusion. Philip seized the throne and drove back his rivals. He now began the great task of his life—the creation of the Macedonian national army. The first experiment he made with this new organism was brilliantly successful. The hill tribes were broken by a single battle in 358, and Philip established his authority inland as far as Lake Ochrida. In the autumn of the same year he took the Athenian colony, Amphipolis, which commanded the gold-mines of Mt. Pangaeus. Their possession was all-important for Philip, and he set there the new city, called after him, Philippi. Athens was temporarily pacified by assurances that Amphipolis would be handed over to her later on. The work of fashioning the Macedonian army occupied Philip for the next few years, whilst his diplomacy was busy securing partisans within the states of Greece. He avoided as yet a forward policy, and having taken Pydna and Potidaea soon after Amphipolis, he made them over to the Olynthian confederation (see OLYNTHUS). His marriage with the fierce witch-woman, Olympias, daughter of the Epipolae king, falls in this period, and in 336 she bore him his greater son, Alexander. In 335 Philip was ready for strong action. He first attacked Abdera and Maronea, on the Thracean sea-board, and then took Methone, which belonged to Athens. An overt breach with Athens was now inevitable. In the same summer he invaded Thessaly, where the Aeolae of Larissa ranged themselves on his side against the tagus Lycombras, "tyrant" of Phereas. Phereas called in the help of the Phocian mercenaries, who had profaned Delphi, and Philip met with a check. He had, however, the advantage of now being able to present himself to the Greeks as the champion of Apollo in a holy war, and in 332 the Macedonian army won a complete victory over the Phocaeans and Phocians. This battle made Philip tagus of Thessaly, and he claimed as his own Magnesia, with the important harbour of Pagoas. Hostilities with Athens did not yet take place, but Athens was threatened by the Macedonian party which Philip's gold created in Euboea.

From 332 to 346 Philip did not again come south. He was active in completing the subjugation of the Balkan hill-country to the west and north, and in reducing the Greek cities of the coast as far as the Hellespont. For the chief of these, indeed, Olynthos, he continued to profess friendship till its neighbour cities were in his hands. Then in 340, he opened war upon it. Athens, to whom Olynthos appealed, sent no adequate forces, in spite of the uprisings of Demothenes (see his OLYNTHIAC), and in the spring of 347 Olynthos fell. Philip razed it to the ground (see OLYNTHS). Macedonia and the regions adjoining it having now been securely consolidated, Philip celebrated his "Olympian" games at Diom. In 347 Philip advanced to the conquest of the eastern districts about the Hellespont, and compelled the submission of the Thracian prince Cersobleptes. Meanwhile Athens had made overtures for peace (see the De falsa legatione of Demothenes), and when Philip, in 346, again moved south, peace was sworn in Thessaly. The time was come for Philip to assert himself in Greece, and the Phocians, who still dominated Delphi and held Thermopylae, could furnish a pretext to the champion of Pan-Hellenism and Apollo. The Phocian mercenaries at Thermopylae were bought off and Philip crossed into central Greece. Here he made Thebes his ally and visited the Phocians with crushing vengeance. The Pythian games of 346 were celebrated at the delivered Delphi under Philip's presidency. Pan-Hellenic enthusiasts already saw Philip as the destined captain-general of a national crusade against Persia (ISOCRATES, PHILIPUS, about 345). And such a position Philip had determined to secure: the Macedonian agents continued to work throughout the Greek states, and in the Peloponnesian Sparta soon found herself isolated. Euboea, too, submitted to Macedonian influence, and even received some garrisons. But more work had to be done in the Balkan highlands. In 344, or one of the following years, the Macedonian arms were carried across Epirus to the Adriatic. In 342 Philip led a great expedition north "comparable to nothing in antiquity since Darius' famous march to Scythia." In 341 his army was still campaigning in eastern Thrace, when Philip felt compelled to show his presence in Thessaly. During these years, although Athens had not overtly broken the peace of 346, there had been various diplomatic bickerings and hostile intrigues between the two powers (cf. the PHILIPICS of Demothenes). Athens had even sent emissaries to the Persian court to give warning of the proposed national crusade. She now egged on the cities of the Propontis (Byzantium, Perinthus, Selymbria), who felt themselves threatened by Philip's Thracian conquests, to declare against him. The sieges of Perinthus and Byzantium (340, 339) ended in Philip's meeting with a signal check, due in some measure to the help afforded the besieged cities by Athens and her allies. Philip's influence all over Greece was compromised. But before marching south he led another expedition across the Balkans into the country now called Bulgaria, and returned to Pella with much spoil but severely wounded in the thigh. In 338 he once more crossed into central Greece. The pretext was the contumacy shown by the Locrian town Amphissa to the rulings of the Amphyctionic Council. Philip's fortification of Elatea filled Athens with alarm. Thebes was induced to join Athens; so were some of the minor Peloponnesian states, and the allies took the field against Philip. This opposition was crushed by the epoch-making battle of Chaeronea, which left Greece at Philip's feet. In the following year (337) Philip was in the Peloponnesus, and a congress of the Greek states met at the Isthmus (from which, however, Sparta held sullenly aloof) recognized Philip as captain-general for the war against Persia. Philip returned to Macedonia to complete his preparations; an advanced force was sent into Asia in the spring of 336. But Philip's plans were suddenly blasted by his assassination in the same year during the marriage festival of his daughter at Aegae, the old capital of Macedonia. He left, however, in the Macedonian army a splendid instrument which enabled his son within ten years to change the face of the world.

Philip stands high among the makers of kingdoms. Restless energy, determination, a faculty for animating and organizing a strong people, went with unscrupulous duplicity and a full-blooded vehemence in the pleasures of sense. Yet Philip was not untouched by ideal considerations, as is proved by the respect, no doubt sincere, which he showed for Hellenic culture, by the forbearance and deference with which he treated Athens, the sacred city of that culture and his mortal foe. A special interest belongs to the Macedonian kingdom as it was shaped by Philip, since it forestalls a system which was not to find the time ripe for it in European history till many centuries later—the national kingdom quickened with the culture developed by the ancient city-states. The national kingdoms founded by the Northern races, after the fall of the Roman Empire, under the influence of the classical tradition, are the beginnings of the modern European system; Philip of Macedon foreshadows Theodoric, Charlemagne and William the Conqueror. But this first national kingdom within the sphere of Greek culture could not ultimately live between the surge of the Northern barbarians and the Roman power.

See the authorities under GRECE: History. A vivid and masterly sketch of Philip's personality and work is given in D. G. Hogarth's Philip and Alexander (1897).

PHILIP III. [AERITHARES], king of Macedonia, was the feeble-minded son of Philip II. of Macedonia by a Thessalian wife. He was chosen by the Macedonian army at Babylon in 323 to be nominal king conjointly with the infant Alexander, and was killed in Macedonia by order of Olympias (317). (See MACEDONIAN EMPIRE.)
PHILIP IV., king of Macedonia, was the son of Cassander, king of Macedonia: he reigned only one year (297–296).

PHILIP V., king of Macedonia, son of Demetrius II. and Chrysea, was an infant at his father’s death in 320–329. His cousin, Antigonus Doson, administered the kingdom as regent till his majority, when Philip was eighteen years old. Philip now ascended the throne and reigned till 179. His reign was occupied in the vain struggle to maintain the old Macedonian supremacy in the Balkan Peninsula, which became hopeless after the intervention of Rome and the decisive battle of Cynoscephalae (197). See Rome: History, § II. “The Republic” (period B, § b).

PHILIP I. (1052–1108), king of France, eldest son of Henry I. of France and Anne, daughter of Jaroslav I. (d. 1054), grand duke of Kiev, came to the throne, when a child of eight, by the death of his father on the 4th of August 1060. He had been crowned at Reims, in the presence of a number of magnates, on the 23rd of May 1059. Philip passed most of his early years in and around Paris, where the castles of lawless barons, such as that of Montlhéry, threatened even his personal safety. His minority came to an end in 1066. In the long reign that followed he showed no great ability or energy, and a looseness of morals which embroiled him with the Church. Before he was fifty years of age he became “fond of nothing but good cheer and sleep.” But he increased the lands of his house, boldly extending Philip’s dominions at the expense of William I. and William II. of England, whose power in France far exceeded his own. This he accomplished for the most part by taking advantage of the quarrels among his vassals. When Baldwin VI. of Flanders died, in 1070, his son Arnulf was attacked by his uncle Robert the Frisian, count of Holland. Philip interfered, at the prayer of Arnulf’s mother, Richildis; but the allies were defeated near Cassel on the 22nd of February 1071 and Arnulf slain. After a second war peace was sealed, apparently, by the marriage of Philip to Robert’s step-daughter Bertha, daughter of Gertrude of Saxony and Florence, count of Holland. In 1074 a new rupture led to Philip seizing Corbie, part of the dower of his aunt Adèle, who had married Baldwin IV. of Flanders. By this he secured a sort of outpost in the direction of Flanders. The other main episodes of his reign were the quarrel over the Angevin inheritance and his wars with the dukes of Normandy. In the struggle between Fulk Rechin and his brother Geoffrey the Bearded for the inheritance of their uncle, Geoffrey Martel (d. 1060), count of Anjou, Philip received from Fulk in 1069, as the price of his neutrality, Château Labon and the Gatinas. This acquisition must have been a great solace, as the Normans were the only enemies he had to fear. Philip’s age ended in a war with the rest of the domain round Pontoise, Melun and Orleans. War with William I. was chronic but intermittent. In 1076 Philip forced him to raise the siege of Dol in Brittany. Peace was made in 1077, and in December 1079 they together besieged Robert Curthose in the castle of Gerberoy. On the 8th of May 1080 the siege was raised and peace made. War with William began again in 1081 over the county of Vexin, which Philip had seized on the retirement of its count, Simon of Valois, to a monastery in 1076. William demanded reparation for the raid of Philip’s vassals and the cession of Pontoise, Chaumont-en-Vexin and Mantes, but died after sacking Mantes in the same year. In 1089 there was war between Philip and William Rufus in both Maine and the Vexin. William came in person from Maine to lead the attack in the Vexin in September, and crossed the Seine, penetrating to within 30 m. of Paris on the west; but the campaign brought no results. In his last years Philip left the duty of repelling the attacks of his Norman and other enemies to his son Louis, associating him with himself, as “king-designate,” some time between the 24th of May 1098 and the 25th of September 1100.

It is believed that Philip was married to Bertha, which was one of Philip’s greatest difficulties. On the 15th of May 1092 he carried off Bertha, daughter of Simon, baron de Montfort, wife of Fulke Rechin, and prepared to marry her, though his wife Bertha was still living. The bishops, headed by Ivo, bishop of Chartres, refused to attend the ceremony of marriage, but one was found to perform it. Philip’s open simony had long been a cause of friction with the papacy. When he added bigamy and adultery, 10 children, he confirmed his alienated state. The bishop of Chartres, in consequence, refused to bring his vassals to help Philip’s ally, Robert, duke of Normandy, against his brother William in 1094. Bertha died in that year, but Fulke was still living, and the sentence was renewed at the council of Autun on the 15th of October. Philip replied by summoning the bishops to Paris to try Ivo of Chartres for treason. He gained a respite from the papal sentence by promises of submission, but the sentence was renewed by Urban at the council of Clermont in 1095, in 1096, and in 1097, and at Poitiers in 1101, despite the protest of William IX., count of Poitiers, who entered the church with his knights to prevent his suzerain from being excommunicated on his lands. Philip was reconciled with the Church in 1104, and took an oath not to have any converse or society with Bertrada except in the presence of “non-suspect” persons. But they seem to have gone on living together, and even visited Fulk Rechin (Bertrada’s husband) in company on the 15th of October 1106. Philip died at the end of July 1108.

His reign is chiefly remarkable for the steady growth of the royal domain. In addition to the gains mentioned, he bought or captured a large slice of territory, including Bouges and Dun-le-Roi, from Eudes, Arpin, vicomte of Bourges, who was going on the crusade; and toward the end of his reign took Montlhéry, whose lord beset the southern approach to Paris. By his first queen he had four children: Louis VI., who succeeded him; Henry, who died young; Charles; and Constance, who married Hugh I., count of Champagne, and later Bohemund I., prince of Antioch. By Bertrada de Montfort he had three children: Philip, count of Montes; Fleury or Florus, who married the heiress of Nangis; and Cecilia, who married, first Tancred, prince of Galilee and Antioch, and secondly Pons de Saint Gilles, count of Tripoli.

PHILIP II. (1165–1223), known as PHILIP AUGUSTUS, king of France, son of Louis VII. and Adela, daughter of Theobald II., count of Champagne, was born on the 15th of September 1165. On the 1st of November 1170 he was associated with his father as king by being crowned at Reims, and at once his father’s illness threw the responsibility of government on him, the death of Louis on the 19th of September 1180 leaving him sole king.

The boy-king found himself and his kingdom in a difficult and humiliating position. His long strip of royal domain was hemmed in by the Angevin Empire on the west and by the kingdom of Arles on the south-east. Henry II. of England was feudal lord of the greater part of France, practically all west of a line which began at Dieppe and ended at the foot of the Pyrenees more than half-way across to the Mediterranean, while at one point it nearly touched the Rhone. Philip’s predecessors had consolidated the Capetian power within these narrow limits, but he himself was overshadowed by the power of his uncles, William, archbishop of Reims; Henry I., count of Champagne; and Theobald V., count of Blois and Chartres. He secured an ally against them, and an addition to the royal domain, by marrying, on the 28th of April 1180, Isabella, the daughter of Baldwin V., count of Flanders, and of Marguerite, sister of Philip of Alsace, the reigning count of Flanders, who ceded Arras, St Omer, Aire and Hesdin, and their districts, as Isabella’s dowry, a district afterwards called Artois. On the 28th of June 1180 Philip made a treaty with Henry II. at Gisors, and his reign thus opened auspiciously. But from 1181 to 1185 he had to struggle against a feudal league of his Champagnard uncles and other great
PHILIP II. (FRANCE) 379

barons, whose most active member was Stephen I., count of Sancerre (1152-1192). Though attacked from both north and south, the king's activity enabled him to compel the count of Sancerre to implore peace in 1181. On the death of Isabel of Vermandois, wife of Count Philip of Flanders, in 1182, Philip claimed Vermandois and seized Chauné and St Quentin, and forced his father-in-law, Baldwin of Hainaut, to support him by threatening to divorce Queen Isabel. The count of Flanders was obliged to sign the treaty of Boves in July 1185, which gave the king, in addition to the expectation of Artois, his wife's dowry, sixty-five castles in Vermandois and the town of Amiens. By 1186 Hugh, duke of Burgundy, the only member of the coalition not yet subdued, was forced to submit. Then, secure at home, the king turned against Henry II., and by the truce of Châteauroux in June 1187, gained Issoudun and the seigniory of Fréteval in the Vendômois. Though the truce was for two years, Philip assembled an army in 1189 to invade Normandy, demanding Gisors and the conclusion of the marriage which had been arranged between his sister Alice and Richard of England, who had meanwhile deserted his father. But the news came that Saladin had taken Jerusalem and Richard took the cross. Shortly afterwards Philip took advantage of a rising against his quondam friend Richard, who was duke of Aquitaine, to seize the county of Berry. At a conference at Bonmoulins on the 18th of November Richard again abandoned his father, and after a second conference at La Ferté Bernard, Philip invaded Maine and forced Henry II. to conclude the treaty of Azay on the 4th of July 1189, by which the English king did homage and surrendered the territories of Gracy and Issoudun. Henry died two days later. Pledges of mutual good faith and fellowship were renewed between Philip and Richard of England on the 30th of December 1189, and they both prepared to go on the crusade.

Before setting out Philip arranged for the government of France during his absence by his famous testament of 1190, by which he proposed to rule France as far as possible from Palestine. The power of the regents, Adela, the queen-mother, and William, archbishop of Reims, was restricted by a council composed mostly of clerks who had the king's confidence. An annual report on the state of the kingdom was to be sent him. On the way to Palestine the two kings quarrelled. At the siege of Acre Philip fell ill, and on the 22nd of July, nine days after its fall, he announced his intention of returning home. He reached Paris at Christmas 1191, having concluded on his way an alliance with the emperor Henry VI. against Richard, despite his pledges not to molest his lands. When Leopold I., duke of Austria, took Richard prisoner and delivered him to the emperor, Philip did his utmost by offers of money to prolong his captivity, and, allied with the English king's brother John, attacked Richard's dominions in the count of Flanders or Otte. Philip's success was due to the support of Philip of Flanders without Philip's consent, and the appearance of his forces in his vassal's continental fiefs. Philip's son Louis, afterwards Louis VIII., married Blanche of Castile, John's niece. But in 1200 the war was renewed, John having seized some castles from the family of Lusignan, whose head was the count of La Marche, and taken for his queen a prospective bride, Isabelle Taillefer, from Hugh, son of Hugh IX., count of La Marche. At an interview at Le Goulet on the 25th of March, Philip demanded the cession of Anjou, Poitou and Normandy to his ward, Arthur. John refused; he was summoned to Paris before the royal judges, and failing to appear was sentenced at the end of April 1202 to lose all his fiefs. Brittany, Aquitaine and Anjou were conferred on Arthur. Philip invaded Normandy, took Lyons-la-Forêt and Eu, and, establishing himself in Gournay, besieged Arques. But John, joined by William des Roches and other lords of Maine and Poitou, jealous at the increase of Philip's power, defeated and took Arthur prisoner at Mirebeau. Philip abandoned the siege of Arques in a fit of fury, marched to the Loire, burning everywhere, and then returned to Paris. But John soon alienated the Poitevin barons, and William des Roches signed a treaty with Philip on the 22nd of March 1203. Then Philip continued his great task, the conquest of Normandy, capturing the towns around the fortress of Château-Gaillard which Richard had built to command the valley of the Seine. Pope Innocent III. tried to bring about peace, but Philip was obdurate, and after murdering Arthur of Brittany John took refuge in England in December 1203. The fall of Château-Gaillard, after a siege which lasted from September 1203 to April 1204, decided the fate of Normandy. Rouen, bound by ties of trade to England, resisted for forty days; but it surrendered on the 24th of June 1204. The conquest of Maine, Touraine, Anjou and Poitou in 1204 and 1205 was little more than a military promenade, though the castles of Loches and Chinon held out for a year. Philip secured his conquest by lavishing privileges on the towns and counties. He left the great lords, such as William des Roches, in full possession of their feudal power. In 1206 he marched through Brittany and divided it amongst his adherents. A truce for two years was made on the 26th of October 1206 by which John renounced all claims in Normandy, Maine, Brittany, Touraine and Anjou, but it did not last six months. Then Poitou was thoroughly subdued, and another truce was made in 1208, little more than southern Saintonge and Gascogne being left in the hands of John. Philip had reduced to a mere remnant the formidable continental empire of the Angevins, which had threatened the existence of the Capetian monarchy.

Philip then undertook to invade England. In the assembly of Soissons on the 8th of April 1213 he made every preparation for carrying out the sentence of deposition pronounced by the pope against John. He had collected 1500 vessels and summoned all his barons when Innocent III., having sufficiently frightened John, sent Pandulf with the terms of submission, which John accepted on the 13th of May.

Disappointed of his hopes of England, Philip turned his arms against Flanders, count of Flanders. Ferdinand, son of Sancho I., king of Portugal, owed his county to Philip, who, hoping to find in him a docile protege, had married him to Jeanne, heiress of Flanders, daughter of Count Baldwin IX., who became emperor of the East, using the weak Philip of Namur, her guardian, to accomplish that end. They were married in January 1212. On the morrow of the marriage Louis, afterwards Louis VIII., seized Aire and St Omer in right of his mother, Isabella, and on this account Ferdinand refused his feudal duty in the English expedition. Moreover, the trade interests of his subjects, who got their raw wool from England, drew him to an alliance with England. Philip's attack brought this about on the 22nd of May 1213. He invaded Flanders and took the chief towns within a week; but he had part of his fleet burned by the English at Damme, and had to burn the rest to save it from falling into their hands. He returned to Paris, and Ferdinand retook most of the towns which had been taken by the king. A war of fire and pillage began, in which Philip and his son Louis burned their way through Flanders, and Ferdinand did the same through Artois.

In 1214 came the great crisis of Philip's life. All the forces against which he had been struggling united to overwhelm him. Paris was to be attacked from Flanders and Guienne at the same time. A league including his rebel vassals, Renaud of Dammartin, count of Boulogne, and Ferdinand, count of Flanders, with the emperor Otto IV. and a number of German princes of the Rhine region, had been formed in the north-east, while John of England
PHILIP II. (FRANCE)

made one more attempt to recover his heritage at the head of an army of mercenaries aided by the fickle baronage of Poitou. John landed at La Rochelle on the 16th of February 1214, and was at first successful. On the 19th of June he laid siege to La Roche-aux-Moines, the fortress which defended Angers and commanded the Loire valley; but on the approach of a royal army under Prince Louis on the 2nd of July his Poitevin barons refused to risk a pitched battle, and he fled hastily to La Rochelle. The Angevin Empire in France was lost. Meanwhile Philip himself won his greatest victory at the bridge of Bouvines, among the morasses of Flanders. At first taken by surprise, he turned the abortive attack into a complete rout. Renaud and Ferdinand were taken prisoners, and Otto IV. fled from the battlefield. The army of the allies was utterly destroyed (July 27, 1214). Nothing shows the progress of the Capetian monarchy more than the enthusiasm and joy of the people of France, as described by William the Breton, over this crowning victory. The battle of Bouvines, a decisive battle for the history of Germany as well as for France and England, sealed the work of Philip Augustus. The expedition of his son Louis to conquer England can hardly be considered as an incident of his reign, though he was careful to safeguard the rights of the French Crown. More important was the Albigensian crusade, in which he allowed Louis to take part, though he himself, preoccupied with the king of England, had refused time after time to do anything. He treated Simon de Montfort as if he were a royal baili; but it was not in virtue of any deep-laid scheme of his that in the end Amaury de Montfort, Simon's son, resigned himself to leave his lands to the Crown of France, and gave the Crown a power it had never before possessed in Languedoc.

Even more than by his conquests Philip II. marks an epoch in French history by his work as an organizer and statesman. He surrounded himself with clerks and legists of more or less humble origin, who gave him counsel and acted as his agents. His baili, who at first rather resembled the itinerant justices of Henry I., were sent into the royal domain to supervise the conduct of the prévôts and hear complaints, while in the newly acquired lands in the south local feudal magistrates were given similar powers with the title of shériff. Feudal service was more and more compounded for by a money payment, while additional taxes were raised, all going to pay the mercenaries with whom he fought Richard I. and John. The extension of the system of souages, by which abbeys, towns or lay vassals put themselves under the special protection of the king, and that of partage, by which the possessor surrendered half the interest in his estate to the king in return for protection or some further grant, increased the royal power. The small barons were completely reduced to submission, whilst the greater feudatories could often appoint a castellan to their own castles only after he had taken an oath to the king. Philip supported the clergy against the feudal lords, and in many cases against the burgesses of the towns, but rigidly excluded from them the performance of their secular duties, ironically promising to aid the clergy of Reims, who had failed to do so, "with his prayers only" against the violence of the lords of Rethel and Roucy. He clung to his right of regale, or enjoyment of the revenues of bishops during their vacancy, though it was at times commuted for a fixed payment. The attempt to raise a tithe for the crusade in 1189 failed, however, before a general resistance owing to an unfair assessment.

It has been said with some justice that Philip II. was the first king of France to take the bourgeoisie into partnership. He favoured the great merchants, granting them trade privileges and monopolies. The Jews he protected and plundered by turns, after the fashion of medieval kings. Amongst the subject towns administered by prévôts a great extension of the "custom of Lorris" took place during his reign. But it is as the ally and protector of the communes that he takes his almost unique place in French history. Before him they were resisted and often crushed; after him they were exploited, oppressed, and finally destroyed. In the case of Sensil he extended the jurisdiction of the commune to all crimes committed in the district. It is true that he suppressed some communes in the newly conquered fiefs, such as Normandy, where John had been prodigal of privileges, but he erected new communes in his own private domain, quite contrary to the custom of other kings. He seems to have regarded them as a kind of garrison against feudal unruliness, while the rents they furnished increased his financial resources. He created no new types of commune, however, except Peronne, which received a maximum of political independence, the twenty-four electors, who named the jurés and other officers, being elected by the corps de métiers.

The newly organized powers of the Crown were in evidence everywhere, interfering in the family affairs of the great feudatories and taking advantage of minorities, such as that of Theobald IV. of Champagne. The great feudatories accepted his legislation on dower in 1214 and 1219 and the établissement of 1200 making co-heirs of fiefs hold direct from the king and not from one of their number. The Tournois was substituted for the Angevin money in Normandy after 1204. The army which agreed to this action was composed entirely of nobles.

The old feudal ost was but rarely convoked. The communes, though they appear as taking part in the battle of Bouvines, compounded for their service by a money payment as early as 1194.

Philp's policy of building up a strong monarchy was pursued with a steadiness of aim which excluded both enthusiasm and scruple. But he seems to have prided himself on a certain humanity, or even generosity of temper, which led him to avoid putting his enemies to death, though he did not scruple to condemn Renaud of Dammartin to the most inhuman of imprisonments. He was impulsive and could display extraordinary activity at times, but he possessed also a certain coldness and caution. He shrank from no trickery in carrying out his ends, and had no room for pity. He could not even trust his own son with any power, and was brutal in his relations with his queen, Ingeborg. He is described by Païen Gâtineau as a "well-knit, handsome man, bale (from his illness at Acre), of agreeable face and ruddy complexion, loving good cheer, wine and women. Generous to his friends, he was miserly to those who displeased him; very skilled in the art of the engineer, catholic in his faith, far-seeing, obstinate in his resolution. His judgment was sound and quick. He was also quick in his anger, but easily appeased." As the result of his steadiness of aim and patient sagacity, at the end of his reign the Crown was victorious over the feudal nobility and the royal domain extended to the frontiers along with royal authority. Artois, the Amienois, Valois, Vermandois, the greater part of the Beauvaisis, Normandy, Maine, Anjou, Touraine, and an important part of Poitou and Saintonge, were added to the domain during his reign. The number of prévôts was increased from thirty-eight to ninety-four, and the royal revenue increased from 16,000 livres a month to 1200 livres a day.

Philip Augustus died on the 14th of July 1223. He was thrice married. His first wife, Isabella, by whom he had one son, was married to him in 1189, but he had her released in 1197. His second wife, a princess of Germany, he married in 1199, but died after a few years. His third wife, Ingeborg, he married in 1204, and she bore him two children, a son, who was called Ingjörg or Ingeborg (q.v.), daughter of Valdemar I. of Denmark. This unlucky marriage was negotiated, it is said, chiefly to acquire the old claims of Denmark over England, to be used as a weapon against Richard I. However that may be, he was soon repudiated this Danish princess, for whom he seems to have conceived an unconquerable aversion on the very morrow of his marriage to her, and in 1196, in defiance of the pope, who had refused to nullify his union with Ingeborg, married Agnes, daughter of Bertold IV., duke of Meran. This led to his excommunication and the interdict upon France, and did more to weaken him than any other act of his. In 1200 he was forced to put away Agnes and to recognize Ingeborg as his lawful wife, but he kept her in prison until 1213. By Agnes (d. 1201) he had a son Philip, called "Huepel," count of Clermont, and a daughter Mary, who married Philip, count of Namur (d. 1219), and then Henry II., duke of Brabant. Ingeborg lived until 1230.

PHILIP III.—IV. (FRANCE)

A. Molinier, Les Sources de l’histoire de France (tome iii, pp. 1–38), gives a complete bibliography of the sources for Philip’s reign, including the period of the Third Crusade.

PHILIP III. (1245-1285), surnamed “the Bold” (le Hardi), king of France, son of Louis IX. and Margaret, daughter of Raymond-Bérenger IV., count of Provence, was born on the 3rd of April 1245. His funeral monument at St Denis depicts a man with beardless, square-cut features, but lacking character and animation. The authenticity of this effigy is fairly well brought out by what is known of him from other sources. He had many of the virtues of St Louis, but neither decision of character nor devotion to duty. He was pious, charitable, of immeasurable morality, quick-tempered but placable, no great scholar, and only energetic as a hunter. The absence in him of the qualities that fit a man to rule made his court the arena of intriguing factions, which in reality ruled France during his reign of fifteen years. Matthew de Vendôme, abbot of St Denis, an old servant of Louis IX., acted as Philip’s counsellor, so the chroniclers state, throughout the reign; but he is only a shadowy figure, and it is difficult to reconcile the statement that “everything was done according to his will” with the known facts. It was probably with administration, and not policy, that Matthew was chiefly concerned. In one instance at least his advice was openly flouted. Coming to the throne by the death of his father on the 25th of August 1270, Philip began his reign by falling entirely under the influence of Pierre de la Brosse, who had been surgeon and valet-de-chambre to his father, upon whom he lavished lands and honours, making him lord (seigneur) of Langais, Châtillon-sur-Indre and Dampierre, count of England and William Dampierre, count of Flanders, strove to win his favour by gifts. But his fall was assured when Philip, who in 1271 lost his first wife, Isabella, daughter of James I., king of Aragon, married in 1274 Marie, daughter of Henry III., duke of Brabant. She was young and beautiful, and supplied a centre round which those who wished the downfall of the favourite grouped themselves. In June 1278 he was charged with various crimes, including one of poisoning his king’s eldest son, and hanged at Montfaucon. His death left the parties of Marie, the queen, and Margaret, the queen-mother, to struggle for the mastery. The first subject of dispute was the inheritance of the count of Provence, Raymond-Bérenger IV., father of Margaret and of Eleanor, wife of Henry III. of England. Upon his death, in 1245, his youngest daughter, Blanche, heiress of his baronial lands and domains, succeeded to his lands, to the exclusion of her elder sisters, who claimed some portion of them for themselves. In 1281 war nearly broke out on this question. Margaret and her friends formed the league of Macon against Charles of Anjou, but the king managed to keep them at peace. The settlement of the claims of the king of England in Aquitaine by the treaty of Amiens in 1279 was a victory for the party of Margaret.

Agenais and southern Saintonge, which fell to the Crown by the death of Alphonse of Poitiers in 1276, as part of his vast possessions in Aquitaine and Languedoc, were ceded to Edward I. of England in accordance with the treaty of Paris 1259. Another portion of the heritage of Alphonse, the Venaisin, was ceded to the papacy to redeem an old promise in general to restore to the pope the strongholds of Philip II. of France. He secretly urged his nephew’s candidacy for the imperial crown, left vacant by the death of Richard of Cornwall, king of the Romans, in 1272, but without success. In May 1275 the party of Marie secured for Philip, the king’s second son, the hand of Jeanne, the heiress of Navarre and Champagne, along with the guardianship of the kingdom of Navarre during the minority of Jeanne. But early in 1276 Jeanne’s mother, Blanche, the widow of Henry III. of Navarre and Champagne, married Edmund, first earl of Lancaster, brother of Edward I.; and she and her English husband kept Champagne until, in 1284, Jeanne came of age.

An expedition of Philip against Castile in aid of the children of his sister, Blanche, proved abortive. Regardless of this warning, he was induced in 1284 to take up the quarrel of his uncle Charles in Sicily, after the Sicilian Vespers in 1282. Two assemblies of barons and prelates were held at Bourges in November 1283 and February 1284 to deliberate on the question. This was a mere matter of form; Marie of Brabant and her party had decided the matter beforehand, and the crown of Aragon, which the French pope Martin IV. had declared forfeited by Peter, was accepted for Charles of Valois, Philip’s third son. The project was strongly opposed by Matthew of Vendôme, who was in correspondence with the king of England on the subject. It was the first warlike expedition undertaken by the house of Capet outside France. It proved a disastrous failure. The French army laid siege to Gerona on the 26th of June 1285. The town surrendered on the 7th of September, but disease and the defeat of the fleet by the Aragonese navy at Las Farmiguanas Islands led to a retreat, during which, on the 3rd of October, the king died. In the same month the garrison placed at Gerona surrendered. It is typical of Philip’s character and career that he should die thus, in an expedition undertaken against the interests of his kingdom, at the instigation of his ambitious uncle.

Philip was twice married. On the 28th of May 1262 he married Isabella, daughter of James I., king of Aragon, who died in 1271. By her he had four children: Louis, who died in 1276; Philip, born in 1268; Charles of Valois, born on the 12th of March 1279; and Robert, who died young. By his second wife, Marie (d. 1232), daughter of Henry III. of Brabant, whom he married in 1274, he had three children: Louis, count of Évreux; Margaret, who married in 1290 Edward I., king of England; and Blanche, who married Rudolph III., duke of Austria.

PHILIP IV. (1268-1314), called “le Bel” or “the Fair,” king of France, was the son of Philip III. and his wife, Isabella of Aragon. His reign, which began in October 1285, is one of the most momentous in the history of medieval Europe, yet it belongs rather to the history of France and to that of the papacy than to the biography of the king. Little is known of the personal part played by Philip in the events which started with his father’s death. They have been divided between the view which regards him as a handsome, lightharted nonentity and that which paints him as a master of statecraft who, under a veil of phlegmatic indifference and pious sentiment, masked an inflexible purpose, of which his ministers were but the spokesmen and executors. The first view seems to be borne out by the language of contemporary chroniclers. To his enemy, Bernard Saisset, he was neither man nor beast, but a statue, “the handsomest man in the world, but unable to do anything but stare fixedly at people without saying a word.” Guillaume de Nogaret, his minister, draws a far more flattering picture, enlarging on his charm, his amiability, his modesty, his charity to all men, and his piety; and the traits of this over-coloured portrait are more or less repeated by his followers. Of Philip, then, we are left with no word of any qualities of will or initiative. All of which suggests a personality mentally and physically phlegmatic, a suggestion strengthened by the fact that Bartholomäus de Neocastro (quoted by Wenc) describes him as corpulent in 1290.

Yet this was the king who with equal implacability brought the papacy under his yoke, carried out the destruction of the powerful order of the Temple, and laid the foundations of the national monarchy of France. In this last achievement Professor Finke finds the solution of a problem which Langlois had declared to be insoluble. In 1302, in the midst of a hostile assembly, Philip cursed his sons should they consent to hold the Crown of any one but God; and in this isolated outburst he sees the key to his character. “Philip was not a man of violent initiative, the planner of daring and fateful operations; otherwise there

Wenc, p. 49.
1 Finke, ii. no. 78, p. 122. Anon. to the commander of Gardeyne and Ashio: "Puol el es rey et papa et emperador! Car tot lo mon sap, quel papa no es nugn et que el fa tot go ques vol del papa et de la eglase.

wish to destroy a body which, with its privileged position and international financial and military organization, constituted a possible menace to the state. He had already persecuted and plundered the Jews and the Lombard bankers, and repeated recourse to the debasement of the coinage had led to a series of small risings. But under his rule something was done towards systematizing the royal taxes, and, as in England, the financial needs of the king led to the association of the people in the work of government.

In 1294 Philip IV. attacked Edward I. of England, then busied with the Scottish War, and seized Guienne. Edward won over the counts of Bar and of Flanders, but they were defeated and he was obliged to make peace in 1297. Then the Flemish cities rose against the French royal officers, and utterly defeated the French army at Courtrai in 1302. The reign closed with the French position unimproved in Flanders, except for the transfer to Philip by Count Robert of Lille, Douai and Béthune, and their dependencies. Philip died the 29th of March, 1314, and his wife was Jeanne, queen of Navarre (d. 1304), through whom that country passed under the rule of Philip on his marriage in 1284; three of his sons, Louis X., Philip V. and Charles IV., succeeded in turn to the throne of France, and a daughter, Isabella, married Edward II. of England.

See the Chronique of Geoffrey of Paris, edited by M. Bouquet, in vol. xxii. of the Recueil des historiens des Gaules et de la France. Of modern works see E. Bataurie, La France sous Philippe le Bel (1861); Dugad, Philippe le Bel (Ste. Claire); C. V. Langlois in L. Lavisse's Histoire de France, vol. iii. (1901); K. Wenck, Philipp der Schöne von Frankreich (Marburg, 1905); H. Finke, Pastorium und Untergang des Templordens, 2 vols. (Münster i.; W. 1907), esp. i. ch. ii.

Philip V. (c. 1294—1322), "the Tall," king of France, second son of Philip the Fair and Jeanne of Navarre, received the county of Poiitiers as an appanage, and was advanced when a year old to Jeanne, daughter and heiress of Otto IV., count of Burgundy. Three days later took place in 1297 when he was thirteen years of age. When his elder brother, Louis X., died, on the 5th of July 1316, leaving his second wife, Clemence of Hungary, with child, Philip was appointed regent for eighteen years by the parliament of Paris, even in the event of a male heir being born. Clemence's son, born on the 15th of November, lived only four days, and Philip immediately proclaimed himself king, though several of the great barons declared that the rights of Jeanne, daughter of Louis X. by his first wife, Margaret of Burgundy, ought to be examined before anything else was done. The coronation at Reims, on the 9th of January 1317, took place with the gates of the city closed for fear of a surprise. The states-general of the 2nd of February 1317, consisting of the nobles, prelates, and the burghers of Paris, approved the coronation of Philip, swore to obey him, and declared that women did not succeed to the Crown of France. The university of Paris approved this declaration, but its members did not take the oath. The Silver law was not involved, and it was later that the lawyers of the 14th century tried to connect this principle to an article of the Salic law, which accords inheritance in land (i.e. property) to males. In the Frankish law the article refers to private property, not to public law. The death of Philip's son Louis, in 1317, disarmed the opposition of Charles, count of La Marche, who now hoped to succeed to the crown himself. Odo or Eudes IV., duke of Burgundy, was married to Jeanne, Philip's daughter, and received the counties of Burgundy as her dower. The barons all did homage except Edward II. of England, and Philip's position was secured. The war with Flanders, which had begun under Philip IV. the Fair, was brought to an end on the 2nd of June 1320. The revolt of the Pastoureaux who assembled at Paris in 1320 to go on a crusade was crushed by the seneschal of Carcassonne, whither they marched. One of the special objects of their hatred, the Jews, were also maltreated heavily by Philip, who exorted 130000 livres from them (1318). Philip died at Longchamp on the night of the 2nd of January 1322.

Philip was a lover of poetry, surrounded himself with Provençal poets and even wrote in Provençal himself, but he was also one of the most hard-working kings of the house of Capet. The
insecurity of his position made him seek the support of national assemblies and of provincial estates. His reign in some ways resembled that of Edward I. of England. He published a series of ordinances organizing the royal household and affecting the financial administration, the “parlement” and the royal forests. He abolished all garrisons in the towns except those on the frontier and provided for public order by allowing the inhabitants of his towns to arm themselves under the command of captains. He tried hard to procure a unification of coinage and weights and measures, but failed owing to the opposition of the estates, who were afraid of the new taxation necessary to meet the loss involved in raising the standard of the coinage, and who held to their local measures and currency partly from conservatism, partly as a relic of local liberty. Philip as a reformer was in many ways before his time, but his people failed to understand him, and he died under the reproach of extortion.

See P. Lehugheur, Histoire de Philippe le Long (Paris, 1897); E. Lavisse, Histoire de France (Tome III, 2); and sources indicated in A. Molinier, Répertoire des sources de l'histoire de France, (1903).

PHILIP VI. (1303-1350), king of France, was the son of Charles of Valois, third son of Philip III., the Bold, and of Margaret of Sicily, and was thus the nephew of Philip IV., the Fair, whose sons, Louis X. Philip V. and Charles IV., died successively without leaving male heirs. He succeeded to the throne on the death of his cousin, Charles IV., in 1328. Before his accession Philip had enjoyed considerable influence, for he was count of Valois, Anjou, Maine, Chartres and Alençon. He had married in 1313 Jeanne (d. 1348), daughter of Robert II. of Burgundy, a determined woman who was long known as the real ruler of France. An expedition to Italy in 1319-20 against Galàs Visconti brought him little glory; he was more successful in a small expedition to Guienne, undertaken against a revolted vassal who was supported by the English.

When Charles IV. died, in February 1328, his wife was enceinte, and it became necessary to appoint a regency until the birth of the child, who would, if a son, succeed to the throne. At the assembly of barons called to choose a regent, Edward III. of England, the nephew and nearest male relation of Charles IV., put in a claim. Edward III., however, descended from the royal house of France by his mother Isabella, and the barons, probably actuated by an objection to the regency of an English king, decided that neither a woman, “nor by consequence her son, could succeed to the kingdom of France,” and Philip of Valois, in spite of his belonging to a junior branch of the family, was elected regent. On the birth of a girl to the queen widow the regency naturally led to the throne of France, and Philip was crowned at Reims on the 29th of May 1328. Navarre had not accepted the regency, that kingdom being claimed by her husband for Jeanne, countess of Evreux, the eldest daughter of Louis X., the count of Evreux himself being, like Philip of Valois, a grandson of Philip the Bold. The new king secured the friendship of the count by allowing Jeanne’s claim to Navarre, in return for a renunciation of any right to Champagne. Edward III. of England, after more than one citation, tendered verbal homage for part of Guienne at Amiens in 1329, but he declined to place his hands between those of Philip VI., and thus formally to acknowledge him as his liege lord. Two years later, however, he forwarded the acknowledgment by letters patent. Meanwhile Philip VI. had won a victory, which he turned into a massacre, at Cassel (August 23, 1328) over Bruges and the other towns of West Flanders, which under the leadership of Jakob van Artevelde had thrown off the authority of their count, Louis of Nevers. The count of Flanders was reinstated, and maintained his authority by a reign of terror.

Much harm was done to Philip VI.’s authority by the scandal arising out of the prosecution of Robert of Artois, count of Beaumont, who was the king’s brother-in-law. The count had presented to the parliament of Paris forged deeds in support of his claim to the county of Artois, held by his aunt, Mahaut, countess of Burgundy. The sudden death of Mahaut, and of her daughter and heiress, Jeanne, widow of Philip V., lent colour to other suspicions, and Robert was driven from France and his goods confiscated. He found refuge, first in Brabant and then at the English court, where he was received as a relative and a victim of false accusations.

Philip VI. enjoyed powerful alliances. In Italy he was allied with his uncle, Robert of Anjou, king of Sicily, and with his former enemy, Galàs Visconti; in the north with the duke of Brabant and the princes of the Netherlands; on the east with the reigning princes of Lorraine and Savoy; with the king of Bohemia and with Pope John XXII. at Avignon, and his successor, Benedict XII. In 1336 it seemed that the Crusade, for which Philip VI. had long been preparing, would at last start; but the relations with Edward III. of England, which had always been strained, became worse, and within a year France was embroiled on the struggle of the Hundred Years’ War. The causes which led to war, the conflict for commercial supremacy in Flanders, disputed rights in Guienne, the help given by France to the Scots, and the unnatural situation of an English king who was also a vassal of the French Crown are dealt with elsewhere (see FRANCE: History). The immediate rupture in Flanders was due chiefly to the tyranny of the count of Flanders, Louis of Nevers, whom Philip VI. had reinstated. Edward III. had won over most of Philip’s German and Flemish allies, and the English naval victory at Sluys (June 24, 1340), in which the French fleet was annihilated, effectually restored English preponderance in Flanders. A truce followed, but this was disturbed after a short duration by the disputed succession to the duchy of Brittany. Edward III. supported John of Montfort; Philip IV. his own nephew, Charles of Blois. A truce made at Malestroit in 1343 at the invitation of the pope, was rudely broken by Philip’s violence. Olivier de Clisson, who with fourteen other Breton gentlemen, was suspected of intrigue with Edward III., was invited to a great tournament in Paris. On their arrival they were murdered by Philip’s orders, and without form of trial beheaded. Then followed Edward III.’s invasion of Normandy and the campaign of Crecy (g.e.). Philip’s army was destroyed; he himself was wounded and fled from the field. He sought in vain to divert Edward from the siege of Calais by supporting the Scots in their invasion of England; but eventually a truce was arranged, which lasted until 1351. Philip VI. died at Nogent-le-roi on the 11th of August 1350.

Philip VI. met his necessities by the imposition of the hated gabelle or salt tax, which was invented by his legal advisers. The value of the coinage fluctuated continuously, to the great hindrance of trade; and although at a meeting of the States-General it was asserted that the king could levy no extraordinary taxes without the consent of the estates, he obtained heavy subsidies from the various provinces. Towards the close of his reign he acquired from Humbert II., comte de Vienne, the province of Dauphiné, and Montpellier from the king of Majorca. These acquisitions made the ultimate annexation of Provence a certainty. Philip married a second wife, Blanche of Navarre. By his first wife he left two sons—his successor, John II., and Philip of Orleans, count of Valois.

PHILIP (c. 1177-1206), German king and duke of Swabia, the rival of the emperor Otto IV., was the fifth and youngest son of the emperor Frederick I. and Beatrix, daughter of Renaut III., count of Upper Burgundy, and consequently brother of the emperor Henry VI. He entered the church, was made provost of Aix-la-Chapelle, and in 1190 or 1191 was chosen bishop of Würzburg. Having accompanied his brother Henry to Italy in 1191, Philip forsook his ecclesiastical calling, and, travelling again to Italy, was made duke of Tuscany in 1195 and received
an extensive grant of lands. In 1196 he became duke of Swabia, on the death of his brother Conrad; and in May 1197 he married Irene, daughter of the eastern emperor, Isaac Angelus, and widow of Roger II., king of Sicily, a lady who is described by Walther von der Vogelweide as "the rose without a thorn, the dove without guile." Philip enjoyed his brother's confidence to a very great extent, and appears to have been designated as guardian of the young Frederick, afterwards the emperor Frederick II., in case of his father's early death. In 1197 he had set out to fetch Frederick from Sicily for his coronation when he heard of the emperor's death and returned at once to Germany. He appears to have desired to protect the interests of his nephew and to quell the disorder which arose on Henry's death, but events were too strong for him. The hostility to the kingship of a child was growing, and after Philip had been chosen as defender of the empire during Frederick's minority he consented to his own election. He was elected German king at Mühlhausen on the 8th of March 1198, and crowned at Mainz on the 8th of September following. Meanwhile a number of princes hostile to Philip, under the leadership of Adolph, archbishop of Cologne, had elected an anti-king in the person of Otto, second son of Henry the Lion, duke of Saxony. In the war that followed, Philip, who drew his principal support from south Germany, met with considerable success. In 1199 he received further accessions to his party and carried the war into his opponent's territory, although unable to obtain the support of Pope Innocent III., and only feebly assisted by his ally Philip Augustus, king of France. The following year was less favourable to his army; and in March 1201 Innocent took the decisive step of placing Philip and his associates under the ban, and began to work energetically in favour of Otto. The two succeeding years were still more unfavourable to Philip. Otto, aided by Ottakar I., king of Bohemia, and Hermann I., landgrave of Thuringia, drove him from north Germany, thus compelling him to seek by abject concessions, but without success, reconciliation with Innocent.

The submission to Philip of Hermann of Thuringia in 1204 marks the turning-point of his fortunes, and he was soon joined by Adolph of Cologne and Henry I., duke of Brabant. On the 6th of January 1205 he was crowned again with great ceremony by Adolph at Aix-la-Chapelle, though it was not till 1207 that his entry into Cologne practically brought the war to a close. A month or two later Philip was loosed from the papal ban, and in March 1208 it seems probable that a treaty was concluded by which a nephew of the pope was to marry one of Philip's daughters and to receive the disputed dukedom of Tuscany. Philip was preparing to crush the last flicker of the rebellion in Brunswick when he was murdered at Bamberg, on the 21st of June 1208, by Otto von Wittelsbach, count palatine in Hauenstein, who, hearing that Philip had refused the hand of one of his daughters. He left no sons, but four daughters; one of whom, Beatrice, afterwards married his rival, the emperor Otto IV. Philip was a brave and handsome man, and contemporary writers, among whom was Walther von der Vogelweide, praise his mildness and generosity.

See W. von Giesebrecht, Geschichte der deutschen Kaiserzeit, Bd. V. (Leipzig, 1888); E. Winkelmann, Philipp von Schwaben und Otto IV. von Braunschweig (Leipzig, 1873-1878); O. Abel, König Ferdinand der Fantasie der Schriftsteller (Stuttgart, 1882), edited by J. Ficker (Innsbruck, 1881); R. Schwemer, Innocens III., und die deutsche Kirche während des Thronstreites von 1198-1208 (Strassburg, 1882); and R. Riant, Innocens III., Philippe de Souabe, et Boniface de Montfort (Paris, 1875).

PHILIP I., the Handsome (1478-1506), king of Spain, son of the emperor Maximilian I., and husband of Joanna the Mad, daughter of Ferdinand and Isabella, was the founder of the Habsburg dynasty in Spain, and was born at Bruges on the 22nd of July 1478. In 1492 he succeeded to the Burgundian possessions of his mother Mary, daughter of Charles the Bold, under the guardianship of his father. In 1496 he married Joanna. The marriage was one of a set of family alliances with Austria and Portugal designed to strengthen Spain against France. The death of John, the only son of Ferdinand and Isabella, opened the succession to the Spanish Crown to Joanna. In 1502 she and her husband received the homage of the cortes of Castile and of Aragon as heirs. Philip returned to Flanders before the close of the year. His life with Joanna was rendered extremely unhappy by his infidelity and by her jealousy, which, working on a neurotic temperament, precipitated her insanity. The princess gave way to paroxysms of rage, in which she was guilty of acts of atrocious violence. Before her mother's death, in 1504, she was unquestionably quite insane, and husband and wife lived apart. When Isabella died, Ferdinand endeavoured to lay hands on the regency of Castile, but the nobles, who disliked and feared him, forced him to withdraw. Philip was summoned to Spain, where he was recognized as king. He landed, with his wife, at Corunna on the 28th of April 1506, accompanied by a body of German mercenaries. Father and son-in-law had interviews at Remesal, near Pueblo de Sénabria, and at Renedo, the only result of which was an indecent family quarrel, in which Ferdinand professed to defend the interests of his daughter, whom he said was imprisoned by his husband. A civil war would probably have broken out between them; but Philip, who had only been in Spain long enough to prove his incapacity, died suddenly at Burgos, apparently of typhoid fever, on the 25th of September 1506. His wife refused for long to allow his body to be buried or to part from it. Philip was the father of the emperors Charles V. and Ferdinand I.

PHILIP II. (1527-1598) king of Spain, was born at Valladolid on the 21st of May 1527. He was the son of the emperor Charles V., and of his wife Isabella of Portugal, who were first cousins. Philip received his education in Spain. His tutor, Dr Juan Martinez Pedernales, who latinized his name to Silicio, and who was also his confessor, does not appear to have done his duty very thoroughly. The prince, though he had a good command of Latin, never equalled his father as a linguist. Don Juan de Zúñiga, who was appointed to teach him the use of arms, was more conscientious; but he had a very poor pupil. From his earliest years Philip showed himself more addicted to the desk than the saddle and to the pen than to the sword. The emperor, who spent his life moving from one part of his wide dominions to another and in the camps of his armies, watched his heir's education from afar. The trend of his letters was to impress on the boy a profound sense of the high destinies to which he was born, the necessity for keeping his nobles apart from all share in the conduct of the internal government of his kingdom, and the wisdom of distrustful counsellors, who would be sure to wish to influence him for their own ends. Philip grew up grave, self-possessed and distrustful. He was beloved by his Spanish subjects, but utterly without the power of attracting men of other races. Though accused of extreme licentiousness in his relations with women, and though he lived for years in adultery with Doña María de Osorio, Philip was probably less immoral than most kings of his time, including his father, and was rigidly abstemious in eating and drinking. His power of work was unbound, and he had an absolute love of reading, annotating and drafting despatches. If he had not become sovereign of the Low Countries, as heir of Mary of Burgundy through his father, Philip would in all probability have devoted himself to warfare with the Turks in the Mediterranean, and to the conquest of northern Africa. Unhappily for Spain, Charles, after some hesitation, decided to transmit the Netherlands to his son, and not to allow them to go with the empire. Philip was summoned in 1548 to Flanders, where he went unwillingly, and was ill regarded. In 1551 he was back in Spain, and intrusted with its government. In 1543 he had been married to his cousin Mary of Portugal, who bore him a son, the unhappy Don Carlos, and who died in 1545. In 1554, when Charles was meditating his abdication, and wished to secure the position of his son, he summoned Philip to Flanders again, and arranged the marriage with Mary, queen of England, who was the daughter of his mother's sister, in order to form a union of Spain, the Netherlands and England, before which France would be powerless. The marriage proved barren. The abdication of his father on the 16th of January 1556 constituted Philip sovereign of Spain with its American possessions, of the Aragonese inheritance
PHILIP III.—IV. (SPAIN)

in Italy, Naples and Sicily, of the Burgundian inheritance—the Netherlands and Franche Comté, and of the duchy of Milan, which his father separated from the empire for his benefit. It was a legacy of immense responsibilities and perils, for France was bound in common prudence to endeavour to ruin a power which encircled her on every side save the sea and threatened her independence. France was for a time beaten at the battles of St Quentin and Gravelines, and forced to make the Peace of Cateau Cambresis (April 2, 1559). But the death of Mary of England on the 17th of November 1558 had deprived Philip of English support. The establishment of Elizabeth on the English throne put on the flank of his scattered dominions another power, forced no less than France by unavoidable political necessities to be his enemy. The early difficulties of Elizabeth's reign secured him a deceitful peace on that side for a time. His marriage with Elizabeth of Valois on the 22nd of June, 1559, and the approach of the wars of religion, gave him a temporary security from France. But the religious agitation was affecting his own Flemish possessions, and when Philip went back to Spain, in August 1559, he was committed to a lifelong struggle in which he could not prove victorious except by the conquest of France and England.

If Philip II. had deserved his name of the Prudent he would have made haste, so soon as his father, who continued to intervene in the government from his retreat at Yuste in Estremadura, was dead, to relieve himself of the ruinous inheritance of the Low Countries. It was perhaps impossible for him to renounce his rights, and his education, co-operating with his natural disposition, made it morally impossible for him to believe that he could be in the wrong. Like the rest of his generation, he was convinced that unity of religion was indispensable to the maintenance of the authority of the State and of good order. Family pride, also, was carried by him to its highest possible pitch. Thus external and internal influences alike drove him into conflict with the Netherlands, France and England; with the first because political and religious discontent combined to bring about revolt, which he felt bound in duty to crush; with the second and third because they helped the Flemings and the Hollanderd. The conflict assumed the character of a struggle between Protestantism and Roman Catholicism, in which Philip appeared as the champion of the Church. It was a part he rejoiced to play. He became, and could not but become, a persecutor in and out of Spain; and his persecutions not only hardened the obstinacy of the Dutch, and helped to exasperate the English, but they provoked a revolt of the Moriscos, which impoverished his kingdom. No experience of the failure of his policy could shake his belief in its essential excellence. That whatever he did was done for the service of God, that success or failure depended on the inscrutable will of the Almighty and not on himself, were his guiding convictions, which he transmitted to his successors. The “service of God and his majesty” was the formula which expressed the belief of the sovereign and his subjects. Philip must therefore be held primarily responsible for the insane policy which brought Spain to ruin. He had a high ideal of his duty as a king to his own people, and had no natural preference for violent courses. The strong measures he took against disorderly elements in Aragon in 1591 were provoked by extreme misconduct on the part of a faction. When he enforced his claim to the crown of Portugal (1579-1581) he preferred to placate his new subjects by paying attention to their feelings and their privileges. He even made dangerous political concessions to secure the support of the gentry. It is true that he was ready to make use of assassination for political purposes; but he had been taught by his lawyers that he was responsible to the state, and as such had a right to act for the public good, legibus solutus. This was but in accordance with the temper of the times. Coligny, Lord Burghley and William the Silent also entered into murder plots. In his private life he was orderly and affectionate to his family and servants. He was slow to withdraw the confidence he had once given. In the painful episode of the imprisonment and death of his firstborn son, Don Carlos, Philip behaved honourably. He bore the acute agony of the disease which killed him with manly patience, and he died piously at the Escorial on the 13th of September 1598.

As an administrator Philip had all the vices of his type, that of the laborious, self-righteous man, who thinks he can supervise everything, is capable of endless toil, and jealous of his authority, and who therefore will let none of his servants act without his instructions. He set the example of the unending discussions in committee and boundless minute writing which finally choked the Spanish administration.

The Histoire de Philippe II. of M. H. Forneron (Paris, 1881), contains many references to authorities and is exhaustive, but the author has more than prejudiced Philip II. in the Martin Hume (London, 1897), it is more just in its treatment of Philip's personal character, and gives a useful bibliography. The main sources for the political history are the Documentos Inéditos para la historia de España (Madrid, 1842, &c.), vols. 1, iii., iv., vols. xxvii., xxviii., xxxiv., and the Actes des états généraux des Pays Bas, 1576-1585 (Brussels, 1861-1866); and the Calendars of State Papers, Foreign Series, Elizabeth (London, 1863-1901). See also Martin Hume, Two English Queens and Philip (1898).

PHILIP III. (1578-1621), king of Spain, son of Philip II. and his fourth wife, Anne, daughter of the emperor Maximilian II., was born at Madrid on the 14th of April 1578. He inherited the beliefs of his father, but no share of his industry. The old king had sorrowfully confessed that God had not given him a son capable of governing his vast dominions, and had foreseen that Philip III. would be led by his servants. This calculation was exactly fulfilled. The new king put the direction of his government entirely into the hands of his favourite, the duke of Lerma, and when he fell under the influence of Lerma's son, the duke of Uceda, in 1581, he trusted himself and his states to the new favourite. The king's own life was passed amid court festivities, on which enormous sums of money were wasted, or in the practice of childish piety. It was said that he was so virtuous as hardly to have committed a venial sin. He cannot be justly blamed for having been born to rule a despotic monarch, without even the capacity which would have qualified him to manage a small estate. He died at Madrid on the 31st of March 1621. The story told in the memoirs of the French ambassador Bassompierre, that he was killed by the heat of a brasero (a pan of hot charcoal), because the proper official to take it away was not at hand, is a humorous exaggeration of the formal etiquette of the court.

R. Watson and W. Thompson, History of Philip III. (1786), give the most available general account of his reign; see also the continuation of Mariana's History of Spain by Miñana (Madrid, 1877-1879).

PHILIP IV. (1605-1665), king of Spain, eldest son of Philip III. and his wife Margaret, sister of the emperor Ferdinand II., was born at Valencia on the 8th of April 1605. His reign, after a few passing years of barren successes, was a long story of political and military decay and disaster. The king has been held responsible for the fall of Spain, which was, however, due in the main to internal causes beyond the control of the most despotic ruler, however capable he had been. Philip certainly possessed more energy, both mental and physical, than his father. There is still in existence a translation of Guicciardini which he wrote with his own hand in order to qualify himself for government by acquiring a knowledge of political history. He was a fine horseman and keen hunter. His artistic taste was shown by his patronage of Velasquez, and his love of letters by his favour to Lope de Vega, Calderon, and other dramatists. He is even credited, on fairly probable testimony, with a share at least in the composition of several comedies. This good internal policy was not a foil to his government. Coming to the throne at the age of sixteen, he did the wisest thing he could by allowing himself to be guided by the most capable man he could find. His favourite, Olivares, was a far more honest man than the duke of Lerma, and was more fit for the place of prime minister than any Spaniard of the time. But Philip IV. had not the strength of mind to free himself from the influence of Olivares when he had grown to manhood. The amusements which the favourite had encouraged became the business of the
PHILIP V. (SPAIN)—PHILIP THE BOLD

king’s life. When, in 1643, the disasters falling on the monarchy on all sides led to the dismissal of Olivares, Philip had lost the power to devote himself to hard work. After a brief struggle with the task of directing the administration of the most extensive and the worst organized monarchy in Europe, he sank back into his pleasures and was governed by other favourites. His political opinions were those he had inherited from his father and grandfather. He thought it his duty to support the German Habsburgs and the cause of the Roman Catholic Church against the Protestants, to assert his sovereignty over Holland, and to extend the dominions of his house. The utter exhaustion of his people in the course of a hopeless struggle with Holland, France and England was seen by him with sympathy, but he considered it an unavoidable misfortune and not the result of his own errors, since he could not be expected to renounce his rights or to desert the cause of God and the Church. In public he maintained a bearing of rigid solemnity, and was seen to laugh only three times in the course of his life. But in private he indulged in horseplay and very coarse immorality. His court was grossly vicious. The early death of his eldest son, Baltasar Carlos was unquestionably due to debauchery encouraged by the gentlemen entrusted by the king with his education. The lesson shocked the king, but its effect soon wore off. Philip IV. died broken-hearted on the 17th of September 1665, expressing the hope that his surviving son, Carlos, would be more fortunate than himself.

The best accounts of Philip IV. will be found in the *Estudios del reinado de Felipe IV.*, by Don A. Cánovas del Castillo (Madrid, 1889); and in the introduction by Don F. Silveira to his edition of the *Cartas de Sor María de Ágreda y del rey Felipe IV.* (Madrid, 1885-1886).

PHILIP V. (1663-1746), king of Spain, founder of the present Bourbon dynasty, was the son of the Dauphin Louis and his wife, Maria Anna, daughter of Ferdinand Maria, elector of Bavaria. He was born at Versailles on the 10th of December 1663. On the extinction of the male line of the house of Habsburg in Spain he was named heir by the will of Charles II. He had shared in the careful education given to his elder brother, Louis, duke of Burgundy, by Fenelon, and was himself known as duke of Anjou. Philip was by nature dull and phlegmatic. He had learnt morality from Fenelon’s teaching, and showed himself throughout his life strongly adverse to the moral laxity of his grandfather and of most of the princes of his time. But his very domestic regularity caused him to be entirely under the influence of his two wives, Maria Louisa of Savoy, whom he married in 1702, and who died in February 1714, and Elizabeth Farnese of Parma, whom he married in December of the same year, and who survived him. He showed courage on the field of battle, both in Italy and Spain, during the War of the Spanish Succession, and was flattered by his courtiers with the title of El Amisone, or the spirited. But he had no taste for military adventure. If he had a strong passion, it was to provide for his succession to the throne of France, if his nephew, Louis XV., should die, and he indulged in many intrigues against the house of Orleans, whose right to the succession was supposed to be secured by Philip’s solemn renunciation of all claim to the French throne, when he became king of Spain. It was in pursuit of one of these intrigues that he abdicated in 1724 in favour of his son Louis. But Louis died in a few months, and Philip returned to the throne. At a later period he tried to abdicate again, and his wife had to keep him in a species of disguised confinement. Throughout his life, but particularly in the later part of it, he was subject to prolonged fits of melancholia, during which he would not even speak. He died of apoplexy on the 9th of July 1746.

The best account of Philip’s character and reign is still that given by Coxe in his *Memoirs of the Kings of Spain of the House of Bourbon* (London, 1816).
at Avignon in 1305 in the hope of obtaining a voluntary resignation from him. But the growing influence of the king’s brother, Louis of Orleans, who was on terms of great intimacy with Queen Isabel and was accused of being her lover, was a serious obstruction. Discord broke out in the council, and but for the intervention of the dukes of Berry and Bourbon the two princes would have come to an open struggle. For a brief period Philip was dispossessed of authority, but he regained it in 1402 and kept it till his death, which took place on the 27th of April 1404. The cathedral of St. Bénigne at Dijon contains his remains, and his tomb (formerly in the Chartreuse of Dijon) is now in the museum in the Hôtel-de-ville.

Although he had to curb the independent spirit of the seigneurs of Franche-Comté, and in spite of frequent collisions with his vassals in Flanders and with the citizens of Besançon (who in 1386 extracted from him a promise to respect their privileges), Philip appears to have governed his territories with sagacity and a certain moderation, and he was particularly successful in employing the resources of France in the interests of Burgundy. He granted numerous privileges to the inhabitants of Dijon, and created in 1386 two chambers des comptes, one at Dijon and the other at Lille. He was, in the phrase of a contemporary, “kindly and amiable to high and low and those of middle rank, liberal as an Alexander, noble and pontifical, in court and state magnificent.” But his liberality and his love of display involved him in enormous expense, and he left so many debts that his widow was compelled to renounce her personal estate to avoid the responsibility of discharging them. By his wife Margaret (d. 1405) he had a numerous family: John the Fearless, who succeeded him; Charles and Louis, who both died in infancy; Anthony, count of Rethel, and Philip, count of Nevers, both killed at Agincourt; Margaret, who married William of Bavaria, count of Ostrevant; Catherine, wife of Leopold, duke of Austria; Mary, wife of Amadeus VIII. of Savoy; and Bonne, who was betrothed to John of Bourbon and died young.

(See below)

PHILIP THE GOOD (1396-1467), duke of Burgundy, son of John the Fearless, duke of Burgundy, and Margaret of Bavaria, was born at Dijon on the 13th of June 1396, and succeeded his father on the 10th of September 1410. The nature of the assassination of John the Fearless (q.v.) was to drive his successor to the English side. In 1419 Philip signed with Henry V. of England the treaty of Arras, by which he recognized Henry as regent and future heir of the kingdom of France, and in 1420 gave his adherence to the treaty of Troyes. Early in December 1420 Philip entered Paris with the king of England, and subsequently took part in the defeat of the French at Mons-en-Vimeu. By a treaty concluded by Philip at Amiens in April 1423 with the dukes of Brittany and Bedford, John, duke of Bedford, married Philip’s sister Anne, and Arthur of Brittany, earl of Richmond, became the husband of Philip’s sister Margaret. A few years later discord arose among the allies. When the duke of Bedford besieged Orleans the inhabitants offered to surrender, but to the duke of Burgundy; whereupon Bedford retorted that “he did not beat the bushes for others to take the birds.” When this speech reached Philip’s ears he withdrew his troops in dudgeon, and concluded a truce with France (1429). Bedford, however, succeeded in conciliating him by promises and presents, and in 1430 Philip took part in the campaign against Compiègne.

But another conflict arose between the duke of Burgundy and the English. Jacqueline, countess of Hainaut, the divorced wife of the duke of Brabant and the heiress of Holland and Zeeland, had married the duke of Gloucester, who attempted to take forcible possession of his wife’s territories. Philip, however, himself claimed Brabant as having been bequeathed to him by his cousin Philip, the late duke, with the result that the Burgundians repulsed the troops of the duke of Gloucester, and Jacqueline was forced to recognize the duke of Burgundy as her lieutenant and herite. Moreover, the duchess of Bedford had died in 1433. Charles VII., who in spite of the efforts of the cardinal of Ste-Croix and the conferences held by him at Auxerre and Semur had hitherto refused to return to France, finally decided to take part in the conferences which were opened at St. Vaast d’Arras on the 6th of August 1435, and to which the whole of Christendom attached very high importance, all the princes of Europe and the pope and the council of Basel being represented. Philip consented to a reconciliation with the king of France, and agreed to recognize him as his legitimate sovereign on condition that he should not be required to pay him homage during his lifetime. Charles, on his part, solemnly craved pardon for the murder of John the Fearless through the mouth of the dean of the church in Paris, and handed over to the duke the counties of Mâcon, Aixerre, Bar-sur-Seine and Pontieux, and the towns on and near the Somme (Roye, Montdidier, Péronne), reserving the option of redeeming the Somme towns for 400,000 gold crowns. Philip proved a faithful ally of the king, aiding him in re-entering Paris and preparing an expedition against Calais, which, however, failed through the ill-will of his Flemish subjects (1436). In 1440 he paid the ransom of Charles of Orleans (the son of his father’s old enemy), who had been a prisoner in England since the battle of Agincourt; received him with great honour at Gravelines; and married him to Mary of Cleves, upon whom he bestowed a handsome dowry. In 1442 Philip entered into a conspiracy to give the duke of Orleans a larger share in the affairs of the kingdom. To René of Anjou, the duke of Lorraine, he showed himself less generous, setting up another claimant to the duchy of Lorraine in the person of Anthony of Vaudemont, and taking René prisoner in 1411; it was not until 1436 that he consented definitively to release René on condition that he should abandon several strong places and pay an enormous ransom. In 1445, at the conferences of Châlons-sur-Marne, the duchess of Burgundy renounced these claims in her husband’s name in order to assure the execution of the treaty of Arras.

Philip was frequently disturbed by the insubordination of the Flemish communes. He had to quell seditions at Liège (1430), Ghent (1432) and Antwerp (1433). In 1438 he drove the duchess out of Bruges by the revolting citizens, their revolt which he repressed with great severity. In 1448 the citizens of Ghent rose in rebellion, but, disappointed of French support, they were defeated at Ruppegmond and in 1453 were overwhelmed at the battle of Gavre, where they lost 20,000 dead on the field. At a banquet shortly afterwards Philip vowed that he would lead a crusade against the Turks, who had seized Constantinople, and the knights of his court swore to follow his example. The expedition, however, did not take place, and was but a pretext for levying subsidies and for knightly entertainments. In 1459 Philip sent an embassy under the duke of Cleves into Italy to take part in the conferences preparatory to a fresh expedition against the Turks, but this enterprise likewise fell to the ground. In 1456 the duke of Burgundy had given an asylum to the Dauphin Louis (afterwards Louis XI.), who had quarrelled with his father and had been forced to leave France. The “fox who would rob his host’s hen-roost,” as the old king called Louis, repaired his protector by attempting to sow discord in the ducal family of Burgundy, and then retired to the castle of Genappe in Brabant. At Charles VII.’s death, however, Philip was one of the first to recognize the new king, and accompanied him to Paris. During the journey Louis won over the seigneurs of Croy, the principal counsellors of the duke of Burgundy, and persuaded Philip to allow him to redeem the Somme towns for the sum stipulated in the treaty of Arras. This proceeding infuriated Philip’s son Charles, count of Charolais, who prevailed upon his father to break his pledge and declare war on the king of France. On the 12th of April 1465 Philip handed over to his son the entire administration of his

4 This was the singular vow known as “the vow of the pheasant,” from the fact that Philip placed his hand solemnly on a pheasant, which had been brought to him by his herald, and vowed that he would fight the Turks and challenge their sultan to single combat.
PHILIP, LANDgrave of Hesse (1504-1567), son of the landgrave William II., was born at Marburg on the 13th of November 1504. He became landgrave on his father's death in 1509, and having been declared of age in 1518, was married in 1523 to Christina, daughter of George, duke of Saxony (d. 1539). In 1522 and 1523 he assisted to quell the rising of Franz von Sickingen (q.v.), who had raised Hesse five years previously, and in 1525 he took a leading part in crushing the rebellion of the peasants in north Germany, being mainly responsible for their defeat at Frankenhausen. About this time Philip adopted the reformed faith, of which he was afterwards the zealous and daring defender. Indifferent to theological, or even to patriotic, considerations, his plans to protect the reformers rested upon two main principles—unity among the Protestants at home and military aid from abroad. The success of his system was as much due to the league of Schmalkalden, aimed primarily at overthrowing the house of Habsburg; to this end aid was sought from foreigner and native, from Protestant and Catholic alike. Envoyes were sent repeatedly to France, England and Denmark; Turkey and Venice were looked to for assistance; the jealousy felt towards the Habsburgs by the Bavarian Wittelsbachs was skilfully fomented; and the German Protestants were assured that attack was the best, nay the only, means of defence. Before the formation of the league of Schmalkalden Philip was very intimate with Zwingli, and up to the time of the reformer's death, in 1531, he hoped that material aid would be forthcoming from his followers. In 1526 he had aided John the Constant, elector of Saxony, to form an alliance of reforming princes; and in 1529 he called together the abortive conference at Marburg, hoping thus to close the breach between Lutherans and Zwinglans. More aggressive was his action in 1528. Deceived by the forgeries of Otto von Pack (q.v.), he believed in the existence of a conspiracy to crush the reformers, and was only restrained from attacking his enemies by the influence of John of Saxony and Luther. He succeeded, however, in compelling the archbishop of Mainz and the bishops of Würzburg and Bamberg to contribute to the cost of his mobilization. Philip was freely accused of having employed Pack to concoct the forgery; and, although this charge is doubtless false, his eager acceptance of Pack's improved statements aroused considerable ill-feeling among the Catholics, which he was not slow to return. In 1529 the landgrave signed the "protest" which was presented to the diet at Speis, being thus one of the original "Protestants." In 1530 he was among the subscribers to the confession of Augsburg; and the formation of the league of Schmalkalden in the same year was largely due to his energy.

His next important undertaking, the restoration of Ulrich, duke of Württemberg (q.v.) to his duchy, was attended with conspicuous success. Württemberg had passed into the possession of the Habsburgs, but after Philip's brief and victorious campaign in 1534 the humiliation of Charles V. and his brother, the German king, Ferdinund I., was so complete that it was said the landgrave had done more for Protestantism by this enterprise than a thousand of Luther's books would do. After this victory Philip entertained the idea of coming to terms with Charles V. on the basis of extensive concessions to the Protestants; but he quickly returned to his former plans for leading a general attack on the Habsburgs. The Concord of Wittenberg, made in 1536, was favourable for these schemes, but after five years spent in assiduous preparation war was prevented by the serious illness of the landgrave and the lukewarmness of his allies. Recovering from his malady, he had returned to his intrigues when an event happened which materially affected the fortunes of the Reformation. His union with Christina was not a happy one, and having fixed his affections upon Margaret von der Saal (d. 1566), he obtained an opinion from Protestant theologians that bigamy was not forbidden by Holy Writ. Luther and Melanchthon at length consented to the marriage, but stipulated that it should be kept secret, and it was celebrated in March 1546. The marriage, however, became known, and a great outcry arose against Philip, whose friends quickly deserted him. He objected to Luther's counsel to deny the existence of a second marriage; abused John Frederick, elector of Saxony, for not coming to support him; and caused bigamy to be publicly defended. Alarmed, however, by the strength of his enemies, and by their evident determination to punish him as a bigamist, he in June 1541 made a treaty with Charles V. at Regensburg. In return for a general pardon he undertook to break off relations with France and England and loyally to support the emperor.

During these years Philip had been forwarding the progress of the Reformation in Hesse. This was begun about 1526, when an important synod was held at Homburg; the university of Marburg was founded in the interests of the reformers in 1527; and after the diet of Spires in 1529 the work was conducted with renewed vigour. The Catholic worship was suppressed, and the secularized church revenues supplied an endowment of the new university.

The peace between the emperor and the landgrave was soon broken. In 1542 Philip persuaded the league of Schmalkalden to attack Henry II., duke of Brunswick-Wolfenbüttel, ostensibly in the interests of the Protestant towns of Brunswick and Goslar. The duchy was quickly over run, and Henry—a Catholic prince—driven out; but the good understanding between the emperor and the landgrave was destroyed, and the relations between Protestants and Catholics became worse than before. Nor was the fissure in the Protestant ranks closed, and Charles took advantage of this disunion to conquer Gelderland and to mature his preparations for overthrowing the league of Schmalkalden. Unlike John Frederick of Saxony, Philip divined, or partly divined, the emperor's intentions, and urged repeatedly that the forces of the league should be put in order. This advice passed unheeded, and when Charles suddenly showed his hand, and in July 1546 issued the imperial ban against the landgrave and the elector, it was seen that the two princes were almost isolated. Fighting began along the upper Danube, and when indecision and want of funds had ruined the league's chances of success, Philip returned to Hesse and busied himself with seeking help from foreign powers; while in April 1547 John Frederick was captured at Mühlberg. After this defeat the landgrave was induced to surrender to Charles in June by his son-in-law, Maurice, now elector of Saxony, and Joachim II., elector of Brandenburg, who promised Philip that he should be pardoned, and were greatly incensed when the emperor refused to assent to this condition. There is, however, no truth in the story that the word einiges was altered by an imperial servant into einiges, thus making the phrase "without any imprisonment" in the treaty of surrender to read "without perpetual imprisonment."
Charles V. at the hands of Maurice in 1552; and after the conclusion of the peace of Passau in this year he returned to Hesse. Although less active than formerly, the landgrave did not cease to intrigue on behalf of the Protestants while continuing the work of reforming and organizing the Church in Hesse. In 1562 he aided the Hugenots with troops, and he was frequently in communication with the insurgents in the Netherlands; but his efforts to form a union of the Protestants were fruitless. Philip, who is sometimes called the Magnanimous, died at Cassel on the 31st of March 1567. By Christina he had four sons and five daughters, and according to his directions the landgraviate was partitioned at his death between his sons. He had also by Margaret von der Saal seven sons, who were called counts of Dietz, and one daughter.

PHILIP, JOHN (1773-1851), British missionary in South Africa, was born on the 14th of April 1775, at Kirkcaldy, Fife, the son of a schoolmaster in that town. After having been apprenticed to a linen-draper, and for three years a clerk in a Dundee business house, he entered the Horton (Congregational) Theological College, and in 1804 was appointed to a Congregational chapel in Aberdeen. In 1818 he joined the Rev. John Campbell in his second journey to South Africa to inspect the stations of the London Missionary Society, and reported that the conduct of the Cape Colonists towards the natives was deserving of strong reprobation. In 1822 the London Missionary Society appointed him superintendent of their South African stations. He made his headquarters at Cape Town, where he also established and undertook the pastorate of the Union Chapel. His indignation was arousal by the barbarities inflicted upon the Hottentots and Kaifers (by a minority of the colonists), and he set himself to remedy their grievances; but his zeal was greater than his knowledge. He misjudged the character both of the colonists and of the natives, his cardinal mistake being in regarding the Afrikaners as a people, and the English as so few to the European in intellect and capacity. It was the period of agitation for the abolition of slavery in England, where Philip's charges against the colonists and the colonial government found powerful support. His influence was seen in the ordinance of 1828 granting all free coloured persons at the Cape every right to which any other British subjects were entitled. During 1826-1828 he was in England, and in the last-named year he published Researches in South Africa, containing his views on the native question. His recommendations were adopted by the House of Commons, but his unpopularity in South Africa was great, and in 1830 he was convicted of libelling a Cape official. The British government, however, caused the Cape government to conform to the views of Philip, who for over twenty years exercised a powerful, and in many respects unfavourable, influence over the destinies of the country. One of Philip's ideals was the curing of colonial "aggression" by the creation of a belt of native reserves and a Native Cape Colony. In Sir Benjamin D'Urban and Philip found a governor anxious to promote the interests of the natives. When however at the close of the Kaffir War of 1834-1835, D'Urban annexed the country up to the Kei River, Philip's hostility was aroused. He came to England in 1836, in company with a Kaffir convert and a Hottentot convert, and aroused public opinion against the Cape government. His views triumphed, D'Urban was dismissed, and Philip returned to the Cape as unofficial adviser to the governor on all matters affecting the natives. For a time his plan of buffer states was carried out, but in 1846 another Kaffir rising convinced him of the futility of his schemes. The Kaffir chief who had accompanied him to England joined the enemy; and many of his converts showed that his efforts on their behalf had effected no change in their character. This was a blow from which he did not recover. The annexation of the Orange River Sovereignty in 1848 followed, finally destroying his hope of maintaining independent native states. In 1849 he severed his connexion with politics and retired to the mission station at Hankey, Cape Colony, where he died on the 27th of August 1851.

See South Africa; History: G. M'C. Theal's History of South Africa since 1705 (London, ed. 1908); Missionary Magazine (1836-1851); R. Wardlaw's Funeral Sermon, 1852.

PHILIP, KING (c. 1639-1676), chief sachsen of the Wampanoag Indians in America, and the son of Massasoit (d. 1662)—as the English, mistaking their (great) chief for a proper name, called Wosamequin (Yellow Feather)—who for forty years was the friend and ally of the English colonists at Plymouth. To Massasoit's two sons, Wamsutta and Metacomet, the English gave the names respectively of Alexander and Philip. Alexander succeeded his father as sachem, and in the same year, while in Marshfield, whither he had gone to explain certain alleged unfriendly acts toward the English, was taken ill; he died on his way home. Philip, who succeeded Alexander, suspected the English of poisoning his brother. The English had grown stronger and more numerous, and had begun to meddle in the internal affairs of the Indians. In 1667 one of Philip's Indians accused him to the English of attempting to betray them to the French or Dutch, but this charge was not proved. In 1671 the Plymouth authorities demanded that the Wampanoags should surrender their arms; Philip consented, but his followers did not comply; and measures were taken to enforce the promise. Philip thereupon went over to the general council, and paid an annual tribute, and not to sell lands or engage in war with other Indians without the consent of the Plymouth government. In 1674, when three Wampanoags were executed at Plymouth for the alleged murder of Sassamon, an Indian convert who had played the part of informer to the English, Philip could no longer hold his followers in check. There were outbreaks in the middle of June 1675, and on the 24th of June the massacre of whites began. There was no concerted movement of the various tribes and the war had not been previously planned. The Nipmuck Indians rose in July; the tribes along the Connecticut river in August; those in the present states of Maine and New Hampshire in September and October, and the Narragansets in December, when (on the 10th) they were attacked and seriously crippled, in what is now the township of South Kingstown, Rhode Island, by the English (under Governor Josiah Winslow of Plymouth), who had no named the Plymouth colony took quick measures of defence, guarded its frontier, maintained its alliance with the Mohegans, and suffered little injury. Massachusetts and Plymouth were slower in acting and suffered great loss. Rhode Island raised no troops, and suffered severely. Early in the autumn Philip went nearly as far west as Albany in an unsuccessful attempt to get aid from the French and the Mohawks and supplies from the Dutch traders. At Deerfield on the 18th of September about 60 English were killed and the settlement was abandoned. In the spring of 1676 it became evident that the Indian power was waning. The warriors had been unable to plant their crops; they were weaker numerically and more poorly armed than the English, and the latter had also made an alliance with the friendly Naticks and the Niantics. On the 1st of August 1676 Philip's wife and nine-year old son were captured, and on the 11th of the same month an Indian traitor guided the English to the sachem's hiding place in a swamp at the foot of Mount Hope (in what is now the township of Bristol, Rhode Island), where early the next morning he was surprised, and while trying to escape was killed by an Indian. The head of Philip was sent to Plymouth and set
PHILIPPA OF HAINAUT—PHILIPPINES

on a pole in a public place, where it remained for a quarter of a century; his right hand was given to his slayer, who preserved it in rags and carried it about by exhibition in the New England towns. The struggle was now over in southern New England, but it continued along the north-eastern frontier till the spring of 1678, and nearly every settlement beyond the Piscataqua was destroyed. In the colonies of Plymouth, Massachusetts, Rhode Island and Connecticut six hundred men (or about 9% of the fighting population), besides many women and children, had been killed; thirteen settlements had been completely destroyed, and about forty others were partly burned. Plymouth had incurred a debt greater than the value of the personal property of her people. The Indians suffered even worse; in addition to the large number of men, women and children slain, great numbers, among them the wife and son of Philip, were sold into slavery in the Spanish Indies and the Bermudas. Many others migrated from New England to New York; and the few remaining Indians, feeble and dispirited, were no longer a power to be reckoned with. Philip was an Indian patriot and statesman, not a warrior; he united the tribes in their resistance to the colonists, but was not a great leader in battle.

See George M. Bodges, Soldiers in King Philip's War (Leominster, Mass., 1869); John Corham Palfrey, History of New England, vol. iii. (Boston, 1864); and especially George W. Ellis and John E. Morris, King Philip's War (New York, 1906). See also Enlisting Passengers Relating to King Philip's War (Boston, 1716), new addition, edited with notes by H. M. Dexter, Boston, 1865, the account by Colonel Benjamin Church (1639-1718), one of the principal leaders of the English, of the warfare in south-eastern New England, in which he took part; it is one of the most famous and realistic accounts of early Indian warfare.

PHILIPPA OF HAINAUT (c. 1314-1366), queen of the English king Edward III., was the daughter of William the Good, count of Holland and Hainaut, and his wife Jeanne de Valois, granddaughter of Philip III. of France. Edward visited the court of Count William in 1336 with his mother Isabella, who immediately arranged the marriage between him and Philippa. After a dispensation had been obtained for the marriage of the cousins (they were both descendants of Philip III.) Philippa was married by proxy at Valenciennes in October 1327, and landed in England in December. She joined Edward at York, where she was married on the 30th of January 1328. Her marriage dower had been seized by the queen dowager Isabella to pay a body of Hainauters, with whose help she had compassed her husband's deposition. The alliance ensured for Edward in his French wars the support of Philippa's influential kindred; and before starting on his French campaign he secured troops from William the Good. as well as from the count of Gelderland, the count of Julick, and the emperor Louis the Bavarian. Her mother Jeanne de Valois, visited her in 1331 and further cemented the community of interests between England and Flanders. Before 1335 Philippa had established a small colony of Flemish weavers at Stratford, and she afterwards interested in the growing trade by repeated visits to the town. She also encouraged coal-mining on her estates in Tyndale. Her eldest son, Edward the Black Prince, was born in 1330, and she subsequently bore six sons and five daughters. In November 1342 she became guardian of John of Gaunt and her younger children, with their lands. Her agents are said to have shown great harshness in collecting the feudal dues with which to supply her large household. The anecdotes of her piety and generosity which have been preserved are proof, however, of her popularity. She interceded in 1331 with the king for some carpenters whose careless work on a platform resulted in an accident to herself and her ladies, and on a more famous occasion her prayers saved the citizens of Calais from Edward's vengeance. There is a generally accepted story, based on the chronicles of Jehan le Bel and Froissart, that she summoned the English forces to meet the Scottish invasion of 1346, and encouraged the troops with her magnificent Cross. She certainly exercised considerable influence over her husband, whom she constantly accompanied on his campaigns; and her death on the 1st of August 1366 was a misfortune for the kingdom at large, since Edward from that time came under the domination of the rapacious Alice Perrers. Philippa was the patron and friend of Froissart, who was her secretary from 1361 to 1366, Queen's College, Oxford, was not, as is stated in Skelton's version of her epitaph, founded by her, but by her chaplain, Robert of Egesfield. Her chief benefactions were made to the hospital of St Katharine's by the Tower, London. See Agnes Strickland, Lives of the Queens of England, vol. i.

In addition to the account given in his Chronicles, Froissart wrote a formal eulogy of her, which has been lost.

PHILIPPEVILLE, a seaport of Algeria, chief town of an arrondissement in the department of Constantine, and 45 m. N. by E. of that city, on the Bay of Stora, in 36° 53' N. 6° 24' E. It is connected by railway with Constantine, Batna and Biskra. The town derives its importance from the port of Constantine. The harbour works, with every vessel in port, having been destroyed by a storm in 1878, a more commodious harbour was built, at a cost of about £1,200,000. From Cape Skikda, on the east a mole or breakwater projects 4,592 ft. to the W.N.W., while from Château Vert on the west another mole runs out 1,131 ft. to the north, leaving an entrance to the port about 96 ft. wide. The protected area comprises an outer and an inner basin. The depth of water at the entrance is about 33 ft., alongside the quays about 20 ft. The quays are faced with blocks of white marble brought from the quarries at Filila, 16 m. distant. Pop. (1906), of the town 16,539, of the commune 26,050, of the arrondissement, which includes 12 communes, 147,607.

Philippeville occupies the site of successive Phoenician and Roman cities. By the Romans, under whom it attained a high state of prosperity, it was named Ruscica. In the middle ages the town ceased to be inhabited. The site was purchased from the Arabs by Marshal Valée in 1838 for £6. Some parts of the Roman theatre remain, but the stones of the amphitheatre, which stood without the walls of the modern town, and which the French found in an almost perfect state of preservation, were used for building purposes, and the roads were cut through the site. On a hill above the town are the Roman reservoirs, which have been restored and still supply the town with water. They are fed by a canal from the Wadi Beni Meleh. The Roman baths, in the centre of the modern town, serve as cellars for military stores.

PHILIPPI (Turk. Filibejik), a city of ancient Macedonia, on a steep hill near the river Gangites (mod. Augista), overlooking an extensive plain and at no great distance from the coast of the Aegean, on the highway between Neapolis (Kavalla) and Thessalonica. Originally called Crenides (Fountains), it took its later name from Philip II. of Macedon, who made himself master of the neighbouring gold mines of the Hill of Dionysus, and fortiied the city as one of his frontier-towns. In 42 B.C., after the victory gained over the senatorial party by Octavius and Antony, it became a Roman colony, Colonia Julia Philippensis, which was probably increased after the battle of Actium (Col. Aug. Julia Phil.). The inhabitants received the Jus Italicum, and Philippus was one of the specially designated "cities" (Acts xvi. 12; see Marquardt, Röm. Staatsverwaltung, i. 187). The city was twice visited by St Paul, whose Epistle to the Philippians was addressed to his converts here. The site, now uninhabited, is marked by ruins—the substructions of an amphitheatre, parts of a great temple—which have furnished interesting inscriptions. A little to the east is the huge stone monument of C. Vibius, known to the Turks as Dikeltashlar and to the Greeks as the Manger of Bucephalus.

See Heuzey and Daumet, Mission arch. en Macédoine, Paris (1865), and other authorities in bibliography of MACEDONIA: Corp. Insr. Loud. (q.v. B.D. E.)

PHILIPPINES, EPISTLE TO THE, a book of the New Testament. Communications had already passed between the Christians of Philipp and Paul, not only when he was at Thessalonica (iv. 15-16), but at some subsequent period (iv. 18), when Epaphroditus had brought him a present of money from them. It is possible that this gift was accompanied by a letter. At any rate the extant epistle is the answer to one received from the Philippian Christians, who had evidently desired information about the
PHILIPPIANS

391

apostle's health and prospects (i. 12), assured him of their prayers (i. 19), and wondered whether he, their pride and glory (καθότιμος), would return to them (i. 25). In this letter, viz. (i. 12), Paul assures them of his loving interest in their present attainments and future progress in the faith of the gospel (i. 3–11); then, relieving their anxiety about his own prospects, he expresses the confident hope that he will be released and thus be able to return to them (i. 12–26). Meanwhile they are to avoid any pride or fastidiousness which might break their unity 1 as a church (i. 27–ii. 18), and they are promised a visit from two of Paul's coadjutors 2 who are well known to them (ii. 19–30). At this point the letter suddenly swerves 3 into a passionate warning against some errorists of Judaism (ii. 1–11), after which the appeal for unity at Philippi is reiterated (iv. 2–5), and the epistle closes with some personal details (iv. 10–23).

Paul is a prisoner when he writes, and the place of composition may therefore be Caesarea or Rome (Acts xxviii. 16, 30–31). The phrase οἷα Ἐκκλησίας (iv. 22) suits Rome better than Caesarea, and, while παράσκευα (i. 13) does not necessarily imply the capital, it is most naturally understood of Rome 4 But the whole tone of the epistle suggests that Paul expected a speedy end to his case. Now at Caesarea this was out of the question. His appeal to Caesar involved a protracted process, and it is very difficult to put expressions like, e.g. of ii. 23 into such a situation.

Paul's exordium is, of course, a turn of phrase, a reminder of his apostolic mission, a pointer to the position of the apostle at Caesarea, or can the latter town be said to have been a centre of vigorous Christian propaganda (i. 17). Finally, the contention that no visit of Timothy to Rome is known is an argument from silence which is of little more weight than the plea of Spitta that the cupidity of Felix (Acts xxiv. 26) was excited by the arrival of the money from Philippi (Phil. iv. 16).

A further examination of the epistle shows that it must have been written towards the close of the διαλόγισμον of Acts xxviii. 30, not in the earlier part of the Roman captivity. Paul is on the edge and eve of the great decision. Behind him (i. 12–13) lies a period during which considerable progress has been made in the local preaching and extension of the gospel, nor does the language of the apostle suggest that this fresh departure in the propaganda was stimulated by the mere novelty of his arrival. Furthermore, the relations between the Philippians and their Levite, or any fair estimate, an interval of time which only a few weeks, not several months, can have reached them; money was collected (ii. 25, iv. 18) and then forwarded by Epaphroditus, who fell sick after he reached the capital; news of this again floated back to Philippi, and subsequently Paul heard of the Philippians' concern (ii. 26). Not till then did he compose this letter.

Philippians is thus the last extant letter we possess from Paul, unless some of the notes embedded in the pastoral epistles are to be dated subsequent to its composition. It unites the close of his career in Rome with the beginning of his mission work in Europe (iv. 15; cf. Acts xvi. 12), and illustrates not merely the situation of the apostle at Rome, but the terms of exceptional affection which existed from first to last between him and the

1 For the strong Christian consciousness of solidarity, presupposed in the Philippians, see Von Dobschutz's Christian Life in the Primitive Church (1875), p. 162.
2 The touch of acerbity in ii. 21 (after i. 14) is probably to be explained by the fact that Paul had found some of the brethren reluctant to undertake a journey to Macedonia, or to perform some other service which he desired, and the words only express the momentary disappointment of a man who was imprisoned and ready to die for the gospel " (Drummond). Cf. Renan's Antichrist (Eng. trans. p. 485.
3 The so-called logion (Justin's) De resurrection, 9: ἐπεί καὶ ἐπήρμησεν τοῦ καθότιμον ὁ θεος, seems a mere echo of ii. 20.
4 On iv. 8 Von Soden notes (History of Early Christian Literature, p. 114) that it is as if we heard the ripple of the waves at the meeting of the two streams which have their source in Zion and the Parthenon.
5 If the expression meant (a) the praefecti praetorio or officials charged with the care of prisoners under trial, i.e. the supreme imperial court, or (b) the praetorian guard, or (c) their barracks, it would almost follow. But conceivably it might mean the palace, i.e. of Herod (Acts xxiii. 35). The balance of probabilities falls, however, in favour of the court hypothesis.

Macedonian churches. The main argument for putting it earlier is derived from the admitted affinities between it and Romans, the Colossian and Ephesian epistles containing; it is held, a more advanced christology (so Lightfoot especially; and Hort, Judaistic Christianity, pp. 113–129). But such considerations are not decisive. Paul wrote from time to time, not in the execution of a literary plan, but as different objects or interests called out his powers. The Philippians did not require, and therefore did not receive, the same elaborate warnings as the Asiatic churches. Hence on the one hand it is unreal to lay stress on coincidences with Romans, as if these necessarily implied that both epistles must have been composed shortly after one another, while again the further stage of thought on Christ and the Church, which is evident in Colossians, does not prove that the latter must have followed the former. Upon the whole, the internal evidence of the epistle strongly favours its position as the last of the captivity epistles.

The attempts made during the 19th century to disprove the Pauline authorship now possess merely an historic interest, nor have the various hypotheses of more or less extensive interpolation won any serious support. More significance attaches to the view that the epistle is made up of two separate notes, the Pauline, to Philippi and the Galilean, to his friends, found in the abrupt hiatus of iii. 1, and evidence is led from supposed inconsistencies between the earlier and the latter parts of the epistle. But the flexibility of a letter-writer, under different moods of feeling, which would naturally lead to rapid transitions, may be adduced as some explanation of the latter phenomena. The exegesis does not absolutely necessitate a partition of the epistle, which (so Heinrichs and Paulus) would make iii. 1–iv. 20 a special letter addressed to some inner circle of the apostle's friends (in spite of iv. 10 seq.), or take iii.–iv. (Hausrath, History of N. T. Times, iv. 162 seq. and Bacon, Story of St Paul, pp. 367 seq.) as earlier than i.–ii. Besides, as Pfeifer points out, the hypothesis is shipwrecked on the difficulty of imagining that "each of the epistles bad but one essential part: the first, in particular, lacking an expression of thanks for the gift from the Philippians, which must nevertheless, according to ii. 25, have already taken place." In his letter to the Philippians (iii. 2) Polycarp indeed observes that Paul wrote πηγήκατος to them; but if they could not be taken as equivalent to a single despatch, it could not necessarily be inferred that the letter is an independent theory of the canonical Philippians. Polycarp may have known of more than one Pauline note to Philippi, no longer extant, or he may be referring loosely to 2 Thessalonians, which was addressed to a neighbouring Macedonian church. The exegetical arguments are, in short, the final court of appeal, and their verdict tells rather in favour of the epistle's integrity. The simplest account of iii. 1 is to suppose that Paul started afresh to complete or supplement what he had already written, possibly because some fresh tidings from Philippi had reached him in the interval. Psychologically the change from ii. 19 seq., with its note of farewell, to the impassioned outburst of iii. 2 seq., is not incredible in an informal letter from a man like Paul. The hiatus is striking, but it cannot be held to necessitate an editorial dovetailing of two separate epistles. It is doubtful, therefore, if the ingenious attempts to analyse Philippians have proved much more convincing than the similar movement of literary criticism upon the first Philippi of Demosthenes, where research has swung back in the main to a conservative position (cf. A. Baron in Wiener Studien, 1884, 172–205).

The first clear echoes of the epistle are heard in Polycarp, though it was probably known to Clement of Rome and Ignatius (cf. the evidence tabulated in The New Testament in the Apostolic Church).

PHILIPPIC, classical literature, a series of orations delivered by Demosthenes against Philip of Macedon. The name was applied to the speeches of Cicero against Mark Antony, and "Philippic" has passed into general use in the sense of an impassioned invective or declamation.

PHILIPPICUS, East Roman emperor, 711–713, was the son of the patrician Nicophorus, and became distinguished as a soldier under Justinian II. His proper name, which indicates his Armenian origin, was Bardanes. Religiously a Monothelite party, he made some pretensions to the throne on the outbreak of the first great rebellion against Justinian; these led to his relegation to Cephalonia by Tiberius Absimarus, and subsequently to his banishment, by order of Justinian, to Cherson. Here Bardanes, taking the name of Philippicus, successfully incited the inhabitants to revolt, and on the assassination of Justinian he at once assumed the purple. Among his first acts were the deposition of Cyrus, the orthodox patriarch of Constantinople, in favour of John, a member of his own sect, and the summoning of a concilium by Eastern bishops, which abolished the canons of the sixth general council. Meanwhile, Theodatus, king of the Bulgarians, plundered up to the walls of Constantinople, and shortly afterwards the Saracens made similar inroads from the Asiatic side. The reign of Philippicus was brought to a close through a conspiracy headed by two of his generals, who caused him to be blinded.

PHILIPPINES, or THE PHILIPPINES, an archipelago belonging to the United States of America, situated about 500 m. off the S.E. coast of Asia between 4° 40' and 21° 10' N, and between 116° 40' and 126° 35' E. It is bounded W. and N. by the China Sea, E. by the Pacific Ocean, and S. by the Celebes Sea and the coastal waters of Borneo. Of the large islands, Luzon (49,069 sq. m.) is the most northerly, and Mindanao (36,922 sq. m.), the most southerly. Between Luzon and Mindanao are Samar (5031 sq. m.), Negros (4881 sq. m.), Panay (4611 sq. m.), Mindoro (3851 sq. m.), Leyte (2722 sq. m.), Cebu (1762 sq. m.), Bohol (1441 sq. m.) and Masbate (1296 sq. m.). Further west and separated from the southern portion of this chain is the long narrow island of Palawan or Paragua (4072 sq. m.). The total land area of the Philippines is about 115,026 sq. m., and 92% of this is included in the eleven islands named above. There are twenty others, which have an area ranging from 106 sq. m. to 692 sq. m., and the total number of islands enumerated within the archipelago is 3141; of these 2775 contain less than 1 sq. m. of land.

Physical Features.—The islands are mainly of volcanic origin, and their surface is much broken by hills, isolated volcanoes and mountain ranges, trending north and south, north-west and south-east, and east and west. The volcanic country along the east coast of central and northern Luzon is the Sierra Madre range, rising in occasional peaks to more than 4500 ft. and seldom less than 3500 ft. On the west coast are the Caraballo Occidentales, and on the east coast the mountains which trend southward from the Luzon Mountain Archipelago to Mindanao and the Celebes Sea. The Caraballo Orientalis are of very complex form; the central ridge is some parts a rolling plateau, but it rises in a mountain range, and numerous lofty spurs project from it. Much of the Zambales range has an average height of 4000 ft. and more, and several peaks are more than 5000 ft. high. Between the Sierra Madre and Caraballo Occidentales is the valley of the Cagayan river, about 50 m. wide, and east of the Zambales range a lowland exist, about 150 m. long and 50 m. wide, and not more than 100 ft. above the sea except in the central part, where its width is 1,500 ft. The extinct volcano of Arayat rises to 3549 ft. The greater part of southern Luzon is occupied by isolated volcanoes and irregular masses of hills and mountains. Mt. Mayon (916 ft.), near the south coast, is a perfect cone and is fringed by a beautiful littoral fringe. Of lesser prominence are Mt. Banáan (7382 ft.), Mt. Isarog (6634 ft.) and Mt. Masaraga (5244 ft.). The island of Mindanao is traversed north to south by mountain ranges, which rise in occasional peaks to more than 1000 ft. Above the sea except in its central portion, where the mountains trend north-west and south-east. The Lower course of this river and the south coast is a mountain range with a north-west and south-east trend. On the south coast of the island is Mt. Iglit, (103,12 ft.), an extinct volcano and the highest elevation in the archipelago.

Each of the larger islands between Luzon and Mindanao, except Samar and Bohol, is traversed longitudinally by a single mountain range with occasional spurs. In Leyte there are several isolated volcanic cones, two of which, in the north part, exceed 4000 ft. In Mindoro the range is broad, extending from coast to coast, and it culminates at Mt Halcón (about 8800 ft.). In Negros is Mt Carloto, (8120 ft.) and several summits exceeding 6000 ft. In Panay is Mt Madaia (7264 ft.) and several other peaks exceeding 4000 ft. The highest peaks in Masbate are about 2500 ft. high, and in Cebú not much more than 2000 ft. In Samar there are a number of isolated ranges, several peaks exceeding 3000 ft. Bohol is a very hilly, but the northern portion is more level. Palawan, 275 m. long and about 15 m. wide, is traversed throughout its length by a range of mountains with an average height of 4000 to 5000 ft. and several peaks exceeding 6000 ft. In the south of the island the ranges connect not only the islands within the archipelago, but also the archipelago itself with Borneo and Celebes, so that only shallow channels connect the interior waters with the Pacific Ocean and the Sea of Borneo. The lowlands of the north and north-east coast of Luzon, about 10,000 sq. m., or nearly one-fourth of the island. The Rio Grande de Mindanao (known in its upper course as the Rio Pulangia) drains to the south and west a large area in central and southern Mindanao. It is about 200 m. wide, and drains to the north-west the mountain valley in east Mindanao, which drains to the north-west the mountain valley in east Mindanao, which drains to the north-west the mountain valley in east Mindanao, which drains to the north-west the mountain valley in east Mindanao, which drains to the north-west the mountain valley in east Mindanao, which drains to the north-west the mountain valley in east Mindanao.
PHILIPPINE ISLANDS

935

Ago rises in the mountains on the north border, flows south, south-west and north-west, and discharges through several channels into the Gulf of Lingayen. Each of these has a great number of small tributaries, and along the coast of this lowland basin are many lagoons and estuaries. The west coast is especially important as a water way from which Laguna de Bay to Manila Bay. The Rio Bicol, which rises in Lake Bato and flows N.N.W. into San Miguel Bay, is the principal river of south Luzon. Samar, Panay, Leyte, Mindanao and the remaining islands are much lower. In fact, a few of those in Samar, Panay and Negros are of considerable size.

In the lowland basin of central Luzon, 6 m. inland from Manila Bay, is Laguna de Bay, the largest body of fresh water in the Philippines. In the southern part of the Bay is a little island, and its coast-line, broken on the north by two hilly peninsulas, is 108 m. long. Lake Taal, a few miles south-west of Laguna de Bay, occurs on the floor of a great volcano. It is 179 m. long and 12 m. wide. The country surrounding the lake is covered with sandstones of various colors, and its mountainous islands are all volcanic rock.

The territory of the area near its centre is the active volcano of Taal, 1050 ft. high. In north Luzon is Lake Cagayan. In Mindanao there are lakes Lanao, Cotabato, and Bulusan in the west-central portion and lakes Maasin, Pinays, and Panguat in the valley of the Agusan. There are small lakes in some of the other islands.

Geology.—The Philippines appear to be the remnants of a somewhat complex system of mountain arcs, which from their similarity of form and direction seem to be in some way connected with the mountain range of Annam. The oldest rocks exposed are gneiss, talc-schist, and serpentinite, with intrusive masses of gabbro and diabase. The formation is overlaid by a limestone, upon which rests conformably a series of sandstone, shale, and conglomerate. The beds are unknown. In some of the islands unmetamorphic limestone (Eocene) occurs. Coral limestones, probably of Middle Tertiary age, are also found, sometimes 4000 ft. above the sea, and marine fossils have been identified. These are seen in the low-lying depressions. Volcanic rocks of modern date cover extensive areas, especially in the southern part of Luzon and Mindanao. In Luzon trachytic tuffs are sometimes interstratified with sandstones. It is often difficult to show that the eruptions had already begun in the Eocene period.

Volcanoes and Earthquakes.—There are twelve active volcanoes in the archipelago. They are Babuyan Claro, Camiguin de Babuyanes and Disulog in the Babuyanes Islands, Apo Cagua or Caua in north Luzon; Taal, Mayon and Bulusan in south Luzon; Canlaon and Magasao in Negros; Camiguin de Mindanao in the island of Camiguin, off the north coast of Mindanao; and Apo and Camiguin the northeastern islands. Only a few have been recorded of any of these, however, except Taal and Mayon, and there has been no great eruption of Taal since 1754. But there were eruptions in 1834, 1849, 1852, and 1887, and of these, those of 1814 and 1897 were of great violence. That of 1897 began practically without warning on the 23rd of June, became alarming on the 24th and destructive on the 25th, and ceased on the 30th. Streams of lava covered and destroyed villages and injured persons, as far as the town of San Fernando. The fluid lava extended more than 7 m. eastward, and a rain of ashes extended 100 m. to the east and 75 m. to the west. There are eight other volcanoes, which although extinct, possess volcanic cones. They are Arroy, Banjao, San Cristobal, Isarog and Malinao in south Luzon, and Macatun and Matutum in Mindanao.

Earthquakes are frequent and occasionally violent. In the seven years ending March 1909, the various regions of the archipelago were visited by about 50 earthquakes; 16 of these, in ten different regions, occurred in the decade from 1890 to 1900. There were in the same decade alone, and of these one of the town of Zamboanga in west Mindanao, and caused considerable loss of life by falling buildings and immense sea waves. A new island appeared at this time off the coast of Bicol. Among the few islands which have been discovered in the history of the kingdom, the largest is the island of Palawan, in the region of Mayon volcano, in the region of Taal volcano, on Masbate island, and along the north shore of Luzon. The islands of Cebu, Bohol, Negros and Palawan are very well marked.

Fauna.—The Philippines, politically speaking, and the Philippines zoologically, are not identical areas; Balabac, Palawan and the Calamianes being characterized by the occurrence of numerous Bird species, the remaining islands by the occurrence of larger groups of mammals. The following list contains the names of the animals that are found on the remaining islands. Although the Philippines are commonly held to form an eastern extension of the Indo-Malayan sub-region, there is a large amount of specialization in the fauna of the islands, characterized by the occurrence of a number of rare species, all of which are found in the island. Some of these species are found in the remaining islands. Although the Philippines are commonly placed among the islands of the region, there are a number of species that are found only in the Philippines, and these are the subject of this section. The species of the philippine islands are divided into two main groups, the Philippine Islands and the Philippine Archipelago.

The native birds are few and are found in the southern part of the islands. The birds that are found in the southern part of the islands are those that are found in the great volcanic area of the islands. The birds that are found in the northern part of the islands are those that are found in the lowlands and the coastal regions. The birds that are found in the lowlands are those that are found in the lowlands and the coastal regions. The birds that are found in the coastal regions are those that are found in the coastal regions.

the cool season, and herons, bitterns and ducks are at all times. The birds of prey, 45 species, of which 22 are peculiar to the group, vary in size from a tiny falcon not larger than a sparrow (Microkara), to an immense monkey-catching eagle (Pithecophaga jefferyi). This is strong enough to seize monkeys as they feed from tree to tree. There are 21 species of hornbills not one occurs outside of the Philippines. Frog-mouths, bee-keepers, night-hawks and swifts are found in considerable variety. One of the last (Clodius), which occurs in the Finlayson range, is found by the Chinese. The best nests are obtained on the precipitous sides of the Peñon de Corom, between Cujon and Busuanuga.

There may also be mentioned 21 cuckoos, 1 cockato, 20 parrots and other birds of song, wood birds, thrushes, thrashers, thras, and many other species, all of which are usually well supplied with food.

Reptiles and batrachians are abundant, but have been little studied. Pythons occur throughout the group, and sometimes attaining enormous size. There are numerous snakes, but the mortality from snake-bite is low. Geckos may be seen on the walls and ceilings of any house. Flying lizards abound in the forests. Large iguanas are numerous. Their eggs are prized by the Chinese, who consider them a delicacy. The large chameleon of the islands is highly esteemed. Crocodiles are extremely numerous in many of the streams, and are occasionally found in the sea along the coasts. Specimens have been obtained measuring 18 ft. in length. Large turtles are also common. They are often captured by the fishermen, and their flesh is highly appreciated as an article of food. A considerable business is done in tortoise-shell. Frogs occur in great variety. One small species approaches in size the very large ant-thrash, as well as a large number of birds for which English names cannot be readily supplied.

Fish, especially marine fishes, are numerous and varied. About 500 species of food fishes have been found, and common among them are the bongos or milkfish, the banak or mullet, mackerel, eels, herring, anchovies and the cap bonito. The "dalag," which is found in the paddy-fields during the wet season, is a favourite with the natives.

The Philippines are famous for the variety, beauty and abundance of their land mussels. Fresh-water and marine mussels are also very numerous. While most of the species are of interest chiefly to the conchologist, there are a number of edible forms. The shells of Placuna placentia, L., split into thin flat plates and coated with a delicate white film, are used as covers for window glass. The valves of the giant clam (Tridacna) sometimes attain a length of 5 ft. and weigh hundreds of pounds. Pearl-oysters are abundant in the southern waters of the archipelago. Peculiar to the Philippines are the so-called "breast-clam" - the valves of the pearl nautilus are commonly used by the Visayans for drinking cups. The great opercula of certain marine forms, bracelets and other ornaments are carved, while the hard shells of the conch and other species are sometimes employed in place of knives for harpoons and spears. While these are thoroughly classified, but much still remains to be done with the marine species.

Arthropoda are very abundant and as yet little known. Shrimps, crabs, lobsters form an important source of food supply. Molluscs are numerous in the wet lowlands. Bees are abundant, and wild honey and wax are gathered in considerable quantities. The number of species of ants is very large. Some of them infest the roots of sugar palms and other trees, while others, so-called "white ants," infest great damage on wooden buildings. Plagues of locusts occasionally, during a drought, ruin growing crops; in damp wet weather these insects are destroyed by a fungus growing on them which turns them into powder.

Land-lacewms swarm in the damp lowland forests. The coral beds of Mindanao and the Sulu Archipelago are of unsurpassed beauty, and Guimaras, Cebu and Siquior are completely covered with large trees in their forests. Flora.—The rich and varied flora of the Philippines is essentially Malay, intermixed with Chinese and Australian elements, but with sufficient individuality to constitute a sub-region, there being at least 700 species peculiar to the archipelago. More than two-thirds of the tropical forests are composed chiefly of broad-leaved trees, common among which are the bamboo, the coco and other palms, and the banyan tree; but on the higher mountains the forests are composed chiefly of coniferous trees, of which the most common are the mahogany, the ebony, the hardwoods, the iroko, the tulipwood, and the cedars. All of these trees are of commercial or local value, among them are woods well suited for structural purposes, inside finishing, cabinet work and carriage making. Plants valuable for their fibre number about 300, and among them is the abaca (Musa textile), from the leaves of which Manila hemp is made. There are gutta-percha, India-rubber and other trees and plants yielding gums, the banana, mango, and many other trees and plants yielding fruits; and various trees and plants yielding nuts, spices, oils, and medicines.

Climate.—A uniformly high temperature, excessive humidity, heavy rainfalls and violent tropical storms, known as typhoons or baguio, are characteristic of the Philippine climate. At Manila the mean annual temperature is about 80° F., the range of mean monthly temperature 6°-8°, from 77° in January to 83.5° in May; and the average temperature (as a mean of the period from 1881 to 1905) 39.9°, from 60.8° in January 1881 to 100.0° in May 1889. In accordance with the monthly variations in temperature at Manila the year is divided into three seasons: temperate (November, December, January and February), the rainy (March, April, and May), and the intermediate (March, July, September and October). Throughout the archipelago the mean annual temperature varies much more with the altitude than with the latitude, but the range in mean monthly temperature is also greater, being 7° in the south-east, 9° in the south-west, and 12° in the north of the islands. The highest temperature, 95°, is in the month of October, when the winds blow from the south-west. During the period from 1865 to 1902 the mean annual rainfall varied from 55.6 in. in 1885 to 173.7 in. in 1867; in July, August, September, and October there was a fall of 57.8 in. In July, August, and September, the rainfall was less in the north than in the south, and during the month of February, March and April only one-tenth of them are rainy. On the Pacific coast of Luzon, Samar, Leyte and Mindanao the rainy season is from November to May, when the winds blow from the east. In the southern and central islands the rainfall is distributed throughout the year. At each station the range of rainfall at 41 observation stations widely distributed throughout the archipelago varied from 16-2 in at Zamboanga in west Mindanao to 152 in. at Masinloc, on the west coast of central Luzon. The Philippines are visited on the average by two typhoons annually.

The production of sugar, tobacco, coco-nuts and rice. Most of the hemp (538,200 acres in 1902) is grown in south Luzon and in Samar and Leyte, while smaller crops are produced in Cebú, Mindoro, Mindanao, Bicol, Panay, and in the island of Negros; the crop became of commercial importance about 1835, and in 1907 the yield for export amounted to 112,965 tons. About two-thirds of the sugar is produced in Negros, but it is an important crop in the provinces of Pampanga and La Union. In the province of Batangas, on the south coast of Luzon, in the south and east of Panay, and in Cebú. The production increased from about 6000 tons in 1855 to 3000,000 tons in 1893, and for many years prior to 1893 was the leading occupation of the island. Since the occupation the crop has been smaller. The total acreage in 1902 was 177,620 acres, and in 1907 the yield for export was 118,955 tons. Approximately one-half of the tobacco, 77,632 acres yielding 1,250,000 lbs. of leaf, and the remainder, which is of inferior quality, in the neighboring provinces of Union, Ilocos Norte and Albur, and in Panay, Cebú, Masbate and Negros. The natives chew betel nuts instead of tobacco, and to the perineal 60,000,000. The rich soil of the lowlands of the province of Laguna is especially well adapted to the culture of the coco-nut palm, and since the American occupation considerable land in this province that had formerly been devoted to sugar
has been planted with these trees. They thrive well also in most lowlands along the coast; in 1902 about 375,000 acres were devoted to the culture of them.

Rice is the staple food of the natives. When the Philippines were ceded to the United States, rice was of great commercial importance, and until the 19th century it was the chief article of export, but as the culture of the more profitable crops of hemp, sugar and coco-nuts was extended it became an article of import. As late as 1893, 62.4% by weight of the rice imported was grown in the provinces of Benguet and Luzon; in 1902 there were in these provinces about 5525 acres of cotton. Many tropical fruits grow wild but their quality is often inferior; these cultivated mainly extensives are mangos and bananas. Grapes, table and champagne varieties, are grown in Central Luzon, where wine has been made for centuries. Hemp has been cultivated in the United States and are grown successfully in the province of Benguet. The natives cure little for the garden vegetables common to Europe and America, but in the vicinity of Manila and other large centres of population grow a large variety of plants for consumption by European and American inhabitants.

With the exception of the water-buffalo, which is indispensable for agricultural purposes, the domestic animals are very inferior in quality and few in numbers. In some provinces, the horses, which are of Spanish and Chinese origin, are small and poorly cared for; some American horses have been introduced for the purpose of improving the breed. The cattle, which are of Australian and Indian origin, are nearly all short-horned. About nine-tenths of them were by the end of the 19th century. Swine are numerous and are of a kind known in the United States as "razorbacks." Ducks are found in great variety, and the principal branch of the poultry industry consists in the raising of game-cocks for cock-fighting, which is the national sport.

Mineral Resources.—Numerous mineral deposits have been discovered, but little has been determined with respect to their value. Sub-bituminous coal is widely distributed. That near the surface of the earth is of inferior quality and few in numbers. Those of larger size are of better quality and are of commercial importance. There are promising fields near Danao, in Cebu; on the island of Polillo, off the coast of Luzon; in the south of Mindoro; on the island of Catanduanes, in the south of Batangas; and on the Island of Mindanao. The largest deposits are in the north of Mindanao; and in the north-east corner of Negros. Gold has been found in small quantities in nearly all the provinces. There is some gold mining by the natives. The gold mines of the Philippines have been operated in the provinces of Benguet and Ambos Camarines in Luzon, and in the island of Masbate. Copper is scarcely less widely distributed than gold, but the production of its occurs in the provinces of Bulacan, Tasay, and in the island of Mindanao. There are extensive deposits of iron ore (magnetite and hematite) in the province of Bulacan, Luzon. Iron ore has been found in other provinces of Luzon and in the islands of Cebu, Panay and Mindanao. There are large deposits of manganese in the province of Marinduque, and in Mindanao considerable silver is associated with the lead. Among other minerals are sulphur, limestone, gypsum and phosphates.

Manufactures.—The manufacturing industry consists mainly in providing the increasing number of foreign residents and the inhabitants, by the natives of wearing apparel, furniture, household utensils, and other articles required to supply their productive wants. The most important factories are those for the manufacture of cotton and sugar, hemp and silk, soap, and paper goods. In the manufacture of sugar most of the mills in use extract only about three-fifths of the juice from the cane; in 1902 about 73% of it was manufactured by 328 miles operated by steam; 47 miles by water; and 77 miles operated by water-power. In the principal rice-producing districts the rice is threshed and cleaned by machines, but in other districts more primitive methods are employed. Most of the cloth which the natives wear the women weave in their own homes. There are three principal varieties: sinamay, which is made from selected hemp fibres and is worn by both men and women; jusi, which is made from a mixture of hemp and pineapple-plant fibres with or without the addition of some cotton and silk and is used for making women’s dresses and men’s shirts; pina, which is made from the fibre of "leaves of the pineapple-plant and is used for making women’s garments, handkerchiefs and scarfs. "Nipa", made from the fibre of the agave or maguey plant and worn by women, is also an important utilitarian fibre. The banana leaf is used as a roof covering and as wrapping for food. The leaves, split bamboo and various grasses. Mats, rugs and carpets are made principally of split bamboo; chairs and beds of baling and other woods and of rattan. Alcohol is distilled from nipa, a peculiar species of palm, pugahan (Caryota urens) and Indian corn. Other manufactures of the natives include vehicles of various kinds, harness, indigo, coco-nut oil, soap, salt and lime.

Population.—The total population of the archipelago was enumerated in the census of 1903 was 7,653,428. Of this number, 6,987,888 were classed as civilized and 674,740 as wild; 7,570,288 or 99.2% were native-born and 56,138 were foreign-born; 7,539,652 were of the Malay or brown race, 4,029,97 were of the yellow race, 24,016 were of the black race, 14,271 were of the white race, and 15,419 were of mixed races. Of the black race 23,511, or 97.8%, were Negritos, who are believed to be the aborigines of the Philippines. Nearly all of these live in a primitive state in the interior of Luzon, Panay, Mindanao and
Negros. They are very short of stature, 4 ft. 10 in. being about the average height of a full-grown man, and the women are short and their colour is black, their skulls decidedly round, their hair thick and frizzy, their legs thin and almost without calves, and their toes so prehensile that they can use them nearly as well as their fingers. They tattoo themselves and wear very little clothing, usually only a geastreng. They have no fixed abodes but roam about in groups of a few families. They are skilful with the bow and in throwing stones, and they can easily kindle a fire, even in the wet season, by rubbing together two pieces of dry bamboo. Their food consists principally of game, roots and wild fruits. The women, who do all the work, collect wax and honey, which are their principal staples in trade. Few Negritos live to be fifty years of age. The brown race, which came from the south in successive waves of immigration beginning in prehistoric times, is composed of twenty-three distinct tribes varying widely in culture, language and appearance; their languages however belong to one common stock and there is a general resemblance in physical features and in quality of mind. The great bulk of the population, approximately 90%, is included in seven Christian tribes as follows: Visayan, 3,719,530; Tagalog, 1,496,922; Bicol, 1,453,980; Pampangan, 280,984; and Cagayán, 159,648. The Visayans are the principal inhabitants of the islands in the central part of the archipelago (Panay, Cebú, Negros, Leyte, Bohol, Samar, Masbate and Paragua) and on the north and east coasts of Mindanao; they were perhaps the most civilized people in the archipelago when discovered by the Spaniards, by whom they were originally called Pintados because they were in the habit of painting their bodies; but since then their progress has been less rapid than that of the Tagálogs—who constitute the bulk of the population of Manila and central Luzon and the majority of the population of Mindanao—who are now the most cultured of the brown races in the Philippines. Most of the Ilocanos are in the western half of north Luzon; most of the Bicolans in south Luzon; most of the Pangasinans in the province of Pangasinan, which borders on the Gulf of Lingayén; most of the Pampangans in the province of Pampanga, which borders the north shore of Manila Bay; and most of the Cagayáns in the valley of the Cagayan River. More than three-fourths of the wild population is included in the Moro, Igorot and Negrito tribes. The Igorots (197,938 wild and 13,382 civilized) are the chief representatives of the early Malay immigration to the archipelago. They are the principal inhabitants of the provinces of Lepanto-Bontoc and Benguet in north Luzon and are numerous in the mountain districts of neighbouring provinces. Among the wildest of their head-hunting is still a common practice; but the majority are industrious farmers laying out their fields on artificial terraces and constructing irrigation canals with remarkable skill. The Moros (275,224 wild and 2323 civilized) were the last of the Malays to migrate to the islands; they came after their conversion to the Mahomedan religion, and their migration continued until the Spanish conquest. More than one-half of them are in Mindanao and they are the principal inhabitants of the small islands of Jolo, Basilan, Siasi and Tawi Tawi south-west of Mindanao. Slavery is common among them. They are generally miserably poor, uneducable and haughty. Nearly three-fourths of the representatives of the Chinese and 97-5% of the representatives of the yellow race come from China. The mixture of the races is principally that of the Chinese with the Malays or the Spaniards with the Malays. More than half the representatives of the white race (1903) were Americans. Most of the inhabitants live in groups of villages. In 1903 there were 13,400 villages and nearly three-fourths of them contained fewer than 600 inhabitants each. Laog in north Luzon with a population of 10,690, Iloilo in Panay with a population of 19,054, Cebú with a population of 16,330, and Nueva Cáceres in south Luzon (10,201), were the only towns with a population exceeding 10,000; and Manila (210,928) was the only city. After the 1903 census many towns were enlarged by annexation of suburbs. 

**Government.**—At the beginning of the American occupation, in August 1898, a purely military government was established; but in May 1899 the military authorities began the re-establishment of civil courts, and in July of the same year they began the organization of civil municipal governments. To continue the work of organizing and establishing civil government the President of the United States appointed in February 1900 a Philippine Commission of five members, with William H. Taft as chairman. On the 1st of September 1900 this body assumed the legislative functions of the central government at Manila; on the 4th of July 1901 the executive authority was, by order of the president, transferred from the military governor to Judge Taft, whom he had appointed civil governor; on the 6th of September 1901 the Philippine Commission, by authority of the president, established the four executive departments, of interior, commerce and police, finance and justice, and public instruction; and on the 29th of October 1901 the president appointed a vice-governor. The Congress of the United States, in an act approved on the 1st of July 1902, ratified and confirmed the government as thus established, but required that future appointments by the president of the governor, vice-governor, members of the commission and heads of the executive departments should be made with the consent of the Senate. The organic act contained a bill of rights, providing for the establishment of a popular assembly of 20 members after the census of 1905, and for the extension of the protection of the United States to the Moro and other southern islands of the Philippines, and more definitely provided for the organization of the judiciary. The first popular assembly, of 80 members, was opened at Manila on the 16th of October 1907, and since then the legislature has been composed of two branches, the Philippine Commission (five Americans and four, formerly three, Filipinos), and the Philippine Assembly. The members of the Assembly are elected by districts (the population of which is approximately equal) for a term of two years. A voter must be twenty-three years of age, must have been a resident of the municipality for six months, must not be a citizen or subject of any foreign country, and must possess at least one of the following qualifications: have been an office-holder under Spanish rule, own real estate worth 500 pesos, pay taxes amounting annually to 30 pesos, or be able to speak, read and write either Spanish or English. The legislature meets annually; a regular session is limited to 90 days, and a special session to 30 days. Justice is administered principally by a supreme court, courts of first instance, and courts of justices of the peace. The supreme court consists of seven members, four Americans and three Filipinos; and the chief justice and associate justices of the supreme court are appointed by the president of the United States with the consent of the Senate. The judges of the courts of first instance are appointed by the governor with the consent of the Philippine Commission. A judgment of the supreme court of the Philippines which affects any statute, treaty, title, right or privilege of the United States may be reversed, modified or affirmed by the Supreme Court of the United States; an appeal to the Supreme Court of the United States may also be had in any cause in which the value in controversy exceeds $25,000. The most common form of provincial government is that by a governor, who is elected biennially by the municipal councillors in convention, and a secretary, a treasurer, a supervisor, and fiscal or prosecuting attorney, who are appointed by the Philippine Commission. Each municipality is governed by a president, treasurer, a supervisor and fiscal or prosecuting attorney, all of whom are elected biennially by the qualified electors of the municipality. The Philippine “municipality” is an administrative area, often sparsely settled, is often called a town, and may be compared to a New England township; the municipalities are the units into which the provinces are divided. Each municipality is made up of barrios or small villages (about 13,400 in the entire archipelago) and of one, or more, more thickly peopled areas, each called a poblacion, and resembling the township “centre” of New England.

**Education.**—The establishment of an efficient system of elementary schools has been an important part of the work of the American administration. Under Spanish rule the Church established colleges and seminaries for training priests, but the Spanish system of secular schools for elementary instruction, established in 1865, accomplished little; the schools were taught by unqualified native teachers and the supervision of them was very lax. The American
system, established by the Philippine Commission in 1901, provides a course of instruction (in the English language) for 11 years: 4 primary, 3 intermediate and 4 secondary. In the intermediate and secondary departments there is a choice of six courses: general, teaching, commerce, agriculture, household and commercial business. The administrative head of the system is the director of education, who is appointed by the commission, and who arranges the course of study, approves the plans for school houses, determines in what points American teachers shall teach, divides the archipelago into school divisions, and appoints a division superintendent in each, and supervises the examination of teachers and the application of Insular school funds. Associated with him is a division inspector, who is also appointed by the commission. In each school division, of which there were 35 in 1908, the division superintendent appoints the native teachers, prepares for the municipal councils estimates of school expenditure, makes appropriations for the Insular school funds. In each municipality there is a school board consisting of the president of the municipality and from four to six other members as the division superintendent shall determine; one-half of them are the eastern boundary of the colony. From the are appointed by the division superintendent. In 1902 there were 928 American teachers employed in the Philippine schools; the employment of American teachers is only a temporary policy, however, and by 1908 the number has been reduced to 795. In 1910 there were more than 6000 Filipino teachers who were teaching English to more than 500,000 pupils. The total number of children of school age in the islands probably reaches 2,000,000. The Insular appropriations for the maintenance of Filipino students at educational institutions in the United States; in 1908 the number so provided for was 130. Besides the elementary schools there are at Manila the Philippine Normal School, the Philippine Institute, the School of the Province, the School of Commerce and the school for the instruction of the deaf and blind, and in 1908 the Philippine legislature passed an act for the establishment of a university of the Philippines.

Financial revenues derive largely from customs duties and internal revenue taxes. In 1909 the receipts were $22,739,000, the expenditure $23,337,000, and the total bonded indebtedness $16,000,000. (N. D. M.)

History.—The Philippine Islands were discovered by Magellan in March 1521. The first island on which he landed was between Samar and Dinagat. Then sailing south he touched at Mindanao, from which he sailed north-west, past Bohol to Cebú. Here he found a good harbour in the bay on which the city of Cebú now stands. He made an alliance with the natives, who undertook to supply him with provisions. With his new allies he crossed to the little island of Mactan, where he was killed in a skirmish. A Portuguese by birth, he had been sailing in the employ of King Charles I. of Spain (the emperor Charles V.), with the object of proving that the Moluccas lay within that part of the world which Pope Alexander VI. and the treaty of Tordesillas (June 7, 1494) had given to Spain and not to Portugal. Magellan named his discovery the Archipelago of Santa Luzara. The Spaniards, however, called the group the Islas de Poniente (Western Islands). The Portuguese called them the Islas de Gricia. The distinction was not accidental. To the Portuguese they could have access by the southern sea, to the Spanish by the western. The Spanish point of view was that the eastern extreme verge of the national domain. In 1529, by the treaty of Saragossa, Spain relinquished to Portugal all claims to the Moluccas, and agreed that no Spanish should trade or sail west of a meridian drawn 297 leagues east of the Moluccas. This was a plain renunciation of any rights over the Philippines, which lie several degrees west of the Moluccas. This fact, however, was ignored and in 1542 an attempt to conquer the Philippines was made by Ruy Lopez de Villabos (c. 1500-1544). Villabos chose to honour the heir-apparent of the Spanish throne by naming some of the islands which he discovered, west and north of Magellan’s discovery, the Islas Filipinas. After the accession of Philip II. (1555-1558) a much more important expedition was fitted out on the Mexican coast, under the direction of the distinguished conquistador, Miguel López de Legaspi (1524-1572). In the sailing directions, issued in 1561, for the use of this expedition, the phrase “las Islas Filipinas” was used as applying to the entire archipelago. Starting on the 2nd of November 1564, from Navidad, with four ships built and equipped on the spot, Legaspi began an enterprise which entitles him to a place among the greatest of colonial pioneers. He was accompanied by five Augustinian friars and four hundred men. In 1565 he founded, on the island of Cebú, San Miguel, the first permanent Spanish settlement in the islands, destined to become the Villa de San-Fint-simo Nombre de Jesus, later the city of Cebú. In 1571 the city of Manila was founded and became the insular capital. Legaspi’s conquest of the islands was facilitated by the fact that there were no established native states, but rather a congeries of small clan-like groups, the headship of which was hereditary. Legaspi was reinforced from time to time by small contingents of troops and friars. Although he encountered enormous obstacles, including famine and mutiny, the hostility and treachery of the natives and of foreigners, and the neglect of the home government, he laid a sure foundation for permanent Spanish occupation.

By a combination of tact, courage and resoluteness he won the hearts of the natives, repelled the Portuguese and, notwithstanding the great distance from Spain, established the new colony on a practical basis. Before his death in 1572 he had explored and pacified a large part of the island territory, had established trade, and had arrested the progress of Mahommedanism.

The conquest of the Philippines was essentially a missionary conquest. Inspired by apostolic zeal the friars braved the terrors of life in the remote villages, raised the natives from barbarianism and taught them the forms of Christianity. As a result of their labours the Christian Filipinos stand unique as the only large mass of Asians converted to Christianity in modern times. The friars promoted the social and economic advancement of the natives, cultivated the national taste for music, introduced improvements in agriculture and imported Indian corn and cacao from America. Tobacco was introduced by the government.

The colonial government was patterned on that of Spanish America. The powers of the governor-general were limited only by the audiencia or supreme court, of which he was president, and by the residenza or official investigation at the expiration of his term. The islands were subdivided into provinces under alcaldes mayores who exercised both executive and judicial functions. The favouritism and corruption that honeycombed the civil service of Spain frequently resulted in placing in responsible positions persons who were entirely untrustworthy. Hairdressers were made into alcaldes, and sailors were transformed into gobernadores by the miraculous grace of royal decrees. The provinces were subdivided into pueblos, each under a native gobernadorcillo, elected annually. The permanent offices could be bought, sold and inherited. The mistake was made of paying very low salaries to the officials, who took this as a justification for illegal exactions. The difficulty of securing proper officials gradually resulted in the more important civil functions being handed over to the friars, who frequently exercised a benevolent despotism. In more than half of the twelve hundred villages there was no other Spaniard beside the priest. The Spanish soldiers were the only other foreigners, and the natives of the southern islands were frequently little narrative history worth recording. There were border wars with rebellious savage tribes, attacks made by Chinese pirates seeking plunder or refuge, volcanic eruptions, earthquakes, tornadoes and the periodical visits of marauders from the southern islands.

In 1762, however, as an incident of the war between Spain and England, a British fleet of thirteen ships, under the command of Admiral Samuel Cornish (d. 1770) and Brigadier-British Occupation of Manila. The available Spanish army consisted of about 500 men, while the attacking force numbered 6930. After a bombardment, Manila fell and on the 5th of October the British entered the city. By the terms of the capitulation the whole of the archipelago was surrendered to the British and an indemnity of 4,000,000 pesos was to be paid. As there was no governor-general at the time, the British were obliged to treat with the acting-governor, the Archbishop Manuel Antonio Rojo; but his authority was set aside by a war-party who rallied around Simon Anda y Salazar, a member of the audiencia. Anda proclaimed himself governor-general and practically
succeeded in confining the British to Manila. At the close of the war the Philippines were returned to Spain. Manila was evacuated in March 1764.

For the first quarter of a century after the Spanish conquest the islands were allowed free trade. Then came the familiar restrictions, limiting commerce to a fixed amount annually, and effectively checking economic development. In 1591 direct trade between the Philippines and South America was prohibited. In 1593 trade between the Philippines and Mexico, the only route open between the colony and Spain, was limited to two ships annually, the ships not to exceed 300 tons burden. The result was that the command of the Acapulco galleon was rarely worth less than $50,000. The passenger fare from Manila to Acapulco, at the end of the 18th century, was $1000. This monopoly lasted until the Mexican War of Independence forced the Spanish government to regard the Philippines as being in the East instead of the West. Spain's colonial policy was not based on an exaltation of the commercial ideal. However much the administrators may have fallen short in actual practice, the Spanish ideal was to preserve and civilize the native races, rather than to establish lucrative trading posts where the natives might be easily exploited. In America the lawgiver provided elaborate safeguards for the protection of the Indians were, to a large degree, nullified by the lust for gold and silver and the consequent demand for labourers in the mines. In the Philippines the humane policy of the home government had no such powerful obstacles to contend with. Business was not developed. The natives were allowed to live the indolent life of the tropics. Compared with the results of English or Dutch colonization the conversion and civilization of the Filipinos is a most remarkable achievement. Notwithstanding the undeniable vices, follies and absurd illiberals of the Spanish colonial régime, the Filipinos were the only group in the East Indies that improved in civilization in the three centuries following their discovery. The chief defect in the Spanish Philippine policy was that while it made converts it did not make citizens. Self-reliance, free-thought and mental growth were not encouraged. Progress in scientific knowledge was effectively blocked by the friars. Their presses confined their activities to the production of catechisms, martyrlogies and handbooks in the native languages after the fashion of the presses of Mexico. Five hundred works were printed and distributed in college alone before 1800. To reach the masses unfamiliar with Spanish, manuals of devotion and outlines of Christian doctrine were translated into the various native languages. Of the Bible itself, no part was translated or published. A knowledge of reading and writing was generally diffused throughout the group.

The era of discontent may be said to have begun in 1825 when the loss of her colonies on the mainland of America caused Spain to take a more immediate interest in the Philippines, and increased emigration to the islands. Between 1840 and 1872 thirty newspapers were founded. The introduction of secular books and papers, more or less surreptitiously, helped to spread the seeds of sedition. In 1832 the Spanish Filipino Bank was established. In 1836 foreign trade, hitherto confined to Manila, was permitted to enter the port of Iloilo, and foreign traders were allowed to open branch houses outside of the capital. The change in Spain's economic policy, including an attempt to exploit the coalfields and to encourage both agriculture and commerce, helped to awaken hitherto dormant sentiments. In 1862 Filipinos were sent to Spain for the education of Spanish youth. In 1878 they had been expelled. In 1859 they were permitted to return on the understanding that they were to devote themselves to education.

The Spanish Revolution of 1868 caused a further influx of Spaniards and also the introduction of the pernicious "spoils system." With every change of ministry in Madrid came a new lot of hungry politicians anxious to fill even the more humble colonial offices. The opening of the Suez Canal in 1869, followed by the establishment of direct steam communication between Spain and the Philippines, sounded the death knell of the peaceful missionary era and brought about the definite entry of the islands into the world of commerce and progress.

The friars, by perpetuating medieval conditions in a country that is now being opened to contact with the civilized world, increased the feeling of discontent. The natural result was a violent conflict. The more advanced Filipinos desired the fulfillment of the decrees of the Council of Trent whereby the incumbencies in Christianized towns and villages should be held by regular clergy and not by friars. Filipinos had, for generations been ordained into priesthood although not received into monastic orders. This measure was really aimed at the political and economic supremacy of the Spanish-born friars, who had by this time acquired 400,000 acres of agricultural land, more than half of it in the vicinity of Manila. The agrarian question added to the growing discontent. All the revolutions began in the province of Cavite, where the friars owned 125,000 acres. In 1872 the secret agents of the friars induced the native garrison at Cavite to mutiny and thus give the friars an excuse to press for vigorous action. The mutiny was not successful, but Father Burgos, the leader of the reform party, was publicly garrotted with three other native priests; and the native clergy were declared to be incompetent to have the cure of souls. Several of the most educated Filipinos were convicted of treason and banished.

With the increased facilities for European travel Filipinos began to visit Europe and return with new and broader notions of life. The most distinguished of the travellers was José Rizal (1861–1896). Born in Calainha, in the province of Luzon, of pure Tagalog parentage, he attended the newly reopened Jesuit university in Manila. He was then sent to Europe to complete his studies, first in Madrid, where he became a doctor of medicine, and later in Germany, where he received the degree of Ph.D. He came into touch with advanced methods of scientific research, acquired great ability as a writer, keen perception of truth and an unfailing realization of the defects of his own people, and the unpleasant but essential fact that to have better government they must first desire it. His propaganda, aimed at the small body of Filipinos who had sufficient education to appreciate political satire, was very effective. His most famous novel, Noli me tangere, was published in 1886. In this he drew a masterly picture, not only of the life and customs of the friars but also of the Filippino chiefs or caciques, subservient to the powers above, tyrannical to those below, superstitious, unprogressive, and grasping. Caciquismo or "bossism," government by local aristocrats, was the prime feature of village life in the islands during the entire period of Spanish rule and existed long before their arrival.

The campaign of Rizal, Marcelo del Pilar, Graciano Lopez Jaena and Apolinario Mabini, the leaders in the "Young Filipino Party," was a protest against both the domination of the friars and economic and administrative caciquismo. To escape the vengeance of the friars, Rizal was obliged to flee to Europe. In 1892 he returned to the islands on the assurance of the governor, Eugenio Despujols y Dusay, that he might live there in peace. His enemies, however, succeeded in having him arrested on a charge of treason. Meanwhile he had organized a reform party under the title of Liga Filipina. Its object had been to procure, by peace means, several reforms in the government of the islands, the chief of which were the expulsion of the friars, and the withdrawal of the governor-general's arbitrary power to deport Filipinos. The friars imported their demand, and met the case half-way by banishing Rizal to Mindanao. Incensed by the failure of their plot, the friars obtained the recall of Despujols.

The new governor, Ramón Blanco, was like Despujols and many of his predecessors, humane at heart, but he could do little more than hold in check the tyrannical schemes of the clergy. The banishment of Rizal convinced the reform party that peaceful endeavour was futile. A secret organization, the Katipunan, was therefore started to secure reforms by force of arms. It was founded by Andrés...
Bonifacio, a schoolmaster of Cavité. In 1895–1896 the friars acting as spies for the government, obtained the banishment of many hundreds of natives.

On the day after the Katipunan conspiracy had been brought prematurely to light by a traitor, three hundred prominent Filipinos were lodged in prison. This precipitated the revolt. The *insurrectos* attacked the civil guard outside the city, but were unsuccessful. A week later some hundreds of insurgents attacked the powder magazine at San Juan del Monte, but were completely routed. Four of their chiefs were taken prisoners and executed in Manila. Ten days after the plot was discovered Manila and five other provinces were officially proclaimed in a state of siege. The *insurrectos* concentrated all their energies upon Cavité province. Several villages fell into their hands. The insurgent commander-in-chief was Emilio Aguinaldo. He was born in 1869 in Cavité, son of a native farmer of considerable ability, and of a half-caste mother whose father was a Chinaman. After attending the Tagálog school at Cavité he entered the Jesuit College in Manila but did not graduate. In 1893 he became municipal alcalde of Cavité, and later joined the Katipunan.

The government was in a difficult position. General Blanco had extremely few European troops at his disposal, and it was doubtful how far native troops could be trusted. Reinforcements were on the way from Spain, but the demands of Cuba had already depleted the Peninsula of the best fighting material. Blanco, blamed for not acting at once, was recalled. In December 1896 General Camilo García de Polavieja (b. 1838) arrived as his successor, with General José Lachambre (b. 1846) as chief of staff. Before Blanco left he had released Rizal and allowed him to go to Spain, but the friars caused his arrest and he was sent back to Manila, where he was executed by Polavieja’s orders in December 1896.

Lachambre took the field in Cavité with energy and succeeded in quelling the rebellion in that province. He was then despatched north. Numerous small battles were fought with Aguinaldo and the insurgents, who were repeatedly defeated only to re-appear in other places. Polavieja’s demand for more troops having been refused, he resigned, and was succeeded in the spring of 1897 by General Fernando Primo de Rivera. Hostilities continued, but the wet season set in, making operations extremely difficult. Before Primo de Rivera could make much headway against the insurgents affairs in Cuba became so serious that the Spanish government cabled him that pacification was most urgently desired. As a result he suspended operations and signed the treaty of Búacabaté (Dec. 12, 1897), by which Aguinaldo and thirty-five of his chief followers were allowed to retire to Hongkong with a cash indemnity of 400,000 pesos. The Madrid government refused to confirm the terms of peace, and the peace rejoicings in Manila were followed by the persecution of all those who were known to have sympathized with the movement.

On the 15th of February 1898 in Havana harbour, the U.S.S. *Maine* was blown up. On the 15th of March Primo de Rivera, learning that the American Commodore George Dewey was on the way, and following his promise to the insurgents, decided to leave his forces in Manila. He left his fleet under the command of the Spanish Admiral Patricio Montojo (b. 1839) stated that, in the event of a conflict, his own fleet would be inevitably destroyed. Primo de Rivera was now recalled and General Basílio Augusti (b. 1840) took his place. With a new governor-general all plans had to be reconsidered. Before suitable defences could be made, word came from Hongkong that Dewey had started for Manila and Montojo hurriedly sailed from Subig Bay to Cavité, barely in time to anchor before Dewey arrived. Few among his crew understood handling a gun properly, and owing to the poor care which his vessels had received they were actually inferior to the individual vessels of the American squadron. Commodore Dewey arrived in the Bay of Manila on the 1st of May, and totally destroyed or disabled the Spanish fleet. The surrender of the city was refused. The Americans occupied Cavité. The battle of Manila Bay and the defeat of the Spanish fleet destroyed the prestige of Spain throughout the islands. Insurrections began in nearly every province. Aguinaldo and his friends were allowed to come to Cavité in an American transport. With the approval of Commodore Dewey, who allowed arms to be supplied him, Aguinaldo successfully renewed his campaign against the Spaniards until practically all Luzon, except the city of Manila and suburbs, was in his control. Reinforcements arrived, and on the 13th of August Manila was taken by the Americans, under General Wesley Merritt (b. 1836).

The refusal of General Merritt to permit Aguinaldo’s troops to enter Manila created resentment on the part of the Filipinos. A so-called constitutional convention was held at Malolos, and a constitution was adopted. At the same time the Visayan Republic was organized, and it professed allegiance to Aguinaldo’s government. Neither Aguinaldo’s government nor the Visayan government was able to maintain order, and the whole country was subject to the boting of robber bands. The treaty of peace between the United States and Spain, by which the Philippine Islands passed into the hands of the former, was signed in Paris on the 10th of December 1898, but it was not confirmed by the Senate until the 6th of February 1899. During this period the Filipinos were left in the lurch. On the 4th of February hostilities broke out between the Americans and the Filipinos. The latter were defeated on the 5th, at Paseo, with heavy loss. The American troops, now under General E. S. Otis (b. 1838), following up the enemy, drove them out of Malolos and then withdrew to Manila to await reinforcements, which brought the total American force up to about 60,000 men. It is unnecessary to trace in detail the gradual conquest of the islands, or the hundreds of engagements, often small, between the rebels and the Americans. Owing to the nature of the country, and the hope of securing independence from a possible overthrow of the Republican party in the United States, the war was prolonged for two or three years. With the capture of Aguinaldo on the 23rd of March 1901, the resistance became little more than that of guerrillas.

Civil government was introduced as fast as possible. During 1899 a Philippine commission, headed by Dr. Jacob G. Schurman of Cornell University, was sent by President McKinley to report on the state of affairs. In February 1900 a second and more powerful commission was appointed, consisting of Judge W. H. Taft, Professor D. C. Worcester (b. 1860), General L. E. Wright (b. 1846), Mr. H. C. Ide (b. 1844), and Professor Bernard Moses (b. 1846). Under the presidency of Mr. Taft it began to exercise a legislative jurisdiction in September 1900. Its first act was to appropriate $1,000,000 for the construction and improvement of roads. It next provided for the improvement of Manila harbour, which involved an expenditure of $3,000,000. The fifth act extended to the islands the benefits of a civil service based on merit. In 1901 a general school law was passed under which 1000 American school teachers were introduced. They were scattered among 500 towns, to teach 2500 Filipino teachers English and modern methods of school teaching. A law for the abolition of the old femal alcalde and provision of a judiciary, a supreme court, the enactment of a code of civil procedure, the establishment of a bureau of forestry, a health department, and an agricultural bureau and a bureau of constabulary, made up of native soldiers officered by white men. Ladrónism was very widely distributed under Spanish rule, and the old guardia civil committed outrages almost equal to those of the brigands themselves. The new constabulary has been eminently successful in maintaining law and order. Great progress has been made in the scientific mapping of the islands.

On the 4th of July 1901 the office of military governor was abolished, the military forces being largely recalled, and the part remaining being made henceforth subordinate to the civil authorities. Mr. Taft became governor-general. A general amnesty was granted to all rebels and political prisoners who would take the oath of allegiance to the United States.
Roosevelt signed an act establishing the civil government of the Philippines and providing for a new legislative body. A census was authorized and was taken in 1900. The act of 1902 also authorized the purchase of land belonging to the friars. Although among such an ignorant and diversified body as that of the Filipinos public opinion can hardly be said to exist, there is no doubt that the hatred of the friars was practically universal. When the revolution came the members of the four orders had to flee for their lives, although the people who killed or imprisoned those who could catch were generally good Catholics. As the insular government could not safely allow the friars to return to their parishes the friars’ lands were bought for $7,000,000. Mr Taft managed the delicate task of negotiating with the Vatican without arousing the hostility of either Catholics or Protestants. On the 1st of February 1904 General L. E. Wright became governor. He was succeeded in 1905 by Mr H. C. Ide, who was succeeded by General James T. Smith in 1906. The elections for the first Philippine A. F. W. Atlee held on the 30th of July 1907, and 31 Nationalists, 26 Progressists, 33 Independents and others were elected. The total vote cast was about 100,000. In many districts the Nationalists’ candidates promised that if they were returned immediate independence would follow. When the Assembly met it became apparent that a great majority were more anxious to act as a dignified branch of the legislature than to maintain consistency with their pre-election declarations. The legislature convened for its second session on the 1st of February 1900. During this session 72 laws were passed, of which 23 had been introduced by the Commission and 49 by the Assembly. Among the acts was one providing for the continuance of Spanish as the official language of the courts until 1913; an act providing for bankruptcy; and an act fixing the age of majority at 21 years.

Governor Smith left the islands in May 1900 and was succeeded by Governor Forbes, who on the 6th of August 1909 the Philippine and Canton had been laid down as the boundaries between the Islands and the United States (see Communications and Commerce). On the 2nd of November 1909 delegates were elected for the second Philippine Assembly. (II. Bl.)

PHILIPPINES (Bulgarian, Plediv; Turkish, Felibe), the capital of Eastern Rumelia, and of the department of Philippopolis, Bulgaria; situated in the midst of picturesque granite mountains, and near the right bank of the river Maritsa, 96 m. E.S.E. of Sofia. The city, 10 m. W. of A. D. Devins, Pop. (1906) 45,574, of whom a large majority are Bulgarians and Turks, with a small number of Greeks, Jews, Armenians or gipsies. Philippopolis is on the main railway from Vienna to Constantinople, via Belgrade and Sofia. The Maritsa is navigable up to this point, and as the city has communication by rail both with the port of Dédagatch on the Mediterranean and that of Burgas on the Black Sea, and is situated in a remarkably fertile country, it has become the chief commercial centre of southern Bulgaria, and is the seat of both Greek and Bulgarian archbishops. The residences of the richer Greeks and Bulgarians occupy the slopes of the largest eminence, the Jambaz-bëg, in the centre of the city; between it and the Nobet-bëg, from the summit of which there is a magnificent view of the city, is the Armenian quarter; near the bridge over the Maritsa is the poorer Turkish quarter; and south-west of the Jambaz-bëg there is a suburb of Turks. On the other side of the river, to the south of the Jambaz-bëg a monument has been erected by the Russians in commemoration of the war of 1877, and near this is the new palace of the king of Bulgaria. The Sahub-bëg is crowned by a clock-tower. Not far from it are the beautiful Exhibition Park laid out in 1892 and the fine Journaidi-Jami Mosque. Near the Maritsa are the remains of the ancient konak (palace) of the Turkish pashas, the public park formed by the Russians in 1877, the gymnasia, and the new Greek cathedral. The city has a large commerce in rice, attic of roses, and cacoons; other exports being wheat, wine, tobacco, alcohol and hides.

Eumolpia, a Thracian town, was captured by Philip of Macedon and made one of his frontier posts; hence its name of Philippiopolis, or “Philip’s City.” Under the Romans Philippiopolis or Triontium became the capital of Thracia; and, even after its capture by the Goths, when 100,000 persons are said to have been slain, it continued to be a flourishing city till it was again occupied by the Bulgarians in 1203. It passed under Turkish rule in 1363; in 1816 it was destroyed by an earthquake; and in 1846 it suffered from a severe conflagration. During the war of 1877-78 the city was occupied by the Russians (see also BULGARIA: History).

PHILIPPUSBURG, a town of Germany, in the grand duchy of Baden, situated on a sluggish arm of the Rhine, 15 m. N. of Karlsruhe, on the railroad Bruchsal-Germersheim. Pop. (1905) 2625. It has manufactures of tobacco and cigars, and some trade in cattle and hops. Philippusburg, formerly an important fortress, originally belonged to the ecclesiastical principality of Spires, and was named Udenheim. In 1338 it was surrounded with walls by bishop Gerhard. A later bishop of Spires, Philipp Christoph von Söttern, made the place his residence early in the 14th century, strengthened the fortifications, and renamed it Philippusburg after himself. At the peace of Westphalia in 1648, the city was left to the Squires, and in 1668 it was once more restored to them. In 1659 the dilapidated fortress fell an easy prey to the French under Marshal Berwick, who, however, lost his life beneath its walls. It was restored to Germany in 1735, and was again besieged by the French in 1799. The town was assigned to Baden in 1803.

See Nopp, Geschichte der Stadt Philippusburg (Philippusburg, 1881).
PHILIPPUS, M. J.—PHILISTINES

PHILIPPUS, MARCUS JULIUS, Roman emperor A.D. 244 to 249, often called "Philip the Arab," was a native of Bostium in Arabia Trachonitis. Having entered the Roman army, he rose to be praetorian prefect in the Persian campaign of Gordian III., and, inspiring the soldiers to slay the young emperor, was raised by them to the purple (244). Of his reign little is known except that he celebrated the secular games with great pomp in 248, when Rome was supposed to have reached the thousandth year of her existence. A rebellion broke out among the legions of Moesia, and Decius, who was sent to quell it, was forced by the troops to put himself at their head and march upon Italy. Philip was defeated and slain in a battle near Verona. According to Christian writers, he was a convert to Christianity.

See Aurelius Victor, Caesares, 28; Eutropius, ix. 3; Zonaras, xii. 145.

PHILIPHS, AMBROSE (c. 1675-1749), English poet, was born in Shropshire of a Leicestershire family. He was educated at Shrewbury school and St John's College, Cambridge, of which he became a fellow in 1699. He seems to have lived chiefly at Cambridge until he resigned his fellowship in 1708, and his pastorals probably belong to this period. He worked for Jacob Tonson the bookseller, and his Pastoral opened the 6th volume of Tonson's Miscellanies (1709), which also contained the pastorals of Pope. Philips was a stanch Whig, and a friend of Steele and Addison. In Nos. 22, 23, 30 and 32 (1713) of the Guardian he was injudiciously praised as the only worthy successor of Spenser. The writer of the papers, who is supposed to have been Thomas Tickell, pointedly ignored Pope's pastorals. In the Spectator Addison applauded him for his simplicity, and for having written English eclogues unencumbered by the machinery of classical mythology. Pope's jealousy was roused, and he sent an anonymous contribution to the Guardian (No. 49) in which he drew an ironical comparison between his own and Philips's pastorals, censuring himself and praising Philips's worst passages. Philips is said to have threatened to cane Pope with a rod he kept hung up at Button's coffee-house for the purpose. It was at Pope's request that Gay burlesqued Philips's pastorals in his Shepherd's Week, but the parody pleased by the very quality of simplicity which it was intended to ridicule. Samuel Johnson describes the relations between Pope and Philips as a "perpetual reciprocation of malevolence." Pope lost no opportunity of scoffing at Philips, who figured in the Bathos and the Dunciad, as Macer in the Characters; and in the "Instructions to a porter how to find Mr Curll's authors" he is a "Pindaric writer in red stockings." In 1718 he started a Whig paper, The Freethinker, in conjunction with Hugh Boulter, then vicar of St Olave's, Southwark. He had been made justice of the peace for Shropshire, was elected attorney-general, and in 1717 a commissioner for the lottery, and when Boulter was made archbishop of Armagh, Philips accompanied him as secretary. He sat in the Irish parliament for Co. Armagh, was secretary to the lord chancellor in 1726, and in 1733 became a judge of the prerogative court. His patron died in 1742, and six years later Philips returned to London, where he died on the 8th of June 1749.

His contemporary reputation rested on his pastoral and epistles, particularly the description of winter addressed by him from Copenhagen (1709) to the earl of Dorset. In T. H. Ward's English Poets, however, he is represented by two of the simple and charming pieces addressed to the infant children of Lord Carteret and of Daniel Pulteney. These were scoffed at by Swift as "little flams on Miss Carteret," and earned for Philips from Henry Carey the nickname of "Namby-Pamby." Philips is also associated with Henry Holland's Life of John Williams (1700): The Thousand and One Days; Persian Tales (1722), from the French of F. Pétis de la Croix; three plays: The Distrest Mother (1712), an adaptation of Racine's Andromaque; The Briton (1722); Humphry, Duke of Gloucester (1723). Many of his poems, which included some translations from Sappho, Anacreon and Pindar, were published separately, and a collected edition appeared in 1748.

PHILIPS, JOHN (1676-1708), English poet and man of letters, son of Dr Stephen Philips, archdeacon of Shropshire, was born at his father's vicarage at Bampton, Oxon, on the 30th of December 1676. He was educated at Winchester and Christ Church, Oxford. He was a careful reader of Virgil and of Milton. In 1701 his poem, The Splendid Shilling, was published without his consent, and a second unauthorized version in 1705 induced him to print a correct edition in that year. The Splendid Shilling, which Addison in The Tatler called "the finest burlesque poem in the British language," recites in Miltonic blank verse the miseries consequent on the want of that piece of money. Its success induced Philips to the notice of Robert Harley and Henry St John, who commissioned him to write a Tory counterblast to Joseph Addison's Campaign. Philips was happier in burlesquing his favourite author than in genuine imitation of a heroic theme. His Marlborough is modelled on the warriors of Homer and Virgil; he rides precipitate over heaps of fallen horses, changing the fortune of the battle by his own right arm. Cider (1708) is modelled on the Georgics of Virgil. Cacalia, an imitation of Milton (1706), although printed without his name, may safely be ascribed to him. In all his poems except Blenheim he found an opportunity to insert a eulogy of tobacco. Philips died at Hereford on the 15th of February 1708/9. There is an inscription to his memory in Westminster Abbey.

See The Whole Works of John Philips, to which is prefixed his Life, by Mr G.[J.] Sewell (3rd ed., 1720); Johnson, Lives of the Poets; and Biographia Britannica.

PHILIPS, KATHARINE (1663-1664), English poet, daughter of John Fowler, a merchant of Buckersbury, London, was born on the 1st of January 1631. Her father was a Presbyterian, and Katharine is said to have read the Bible through before she was five years old. On arriving at years of discretion she broke with Presbyterian traditions in both religion and politics, became an ardent admirer of the king and his church policy, and in 1647 married James Philips, a Welsh royalist. Her home at the Priory, Cardigan, became the centre of a "society of friendship," the members of which were known to one another by fantastic names, Mrs Philips being "Orinda," her husband "Antenor," Sir Charles Cotterel "Poliarchus." The "matchless" Orinda, as her admirers called her, posed as the apostle of female friendship. There was much solid worth under her affectations, and she procured the respect and friendship she inspired. Jeremy Taylor in 1659 dedicated to her his "Discourse on the Nature, Offices and Measures of Friendship," and Cowley, Henry Vaughan the Silurist, the earl of Roscommon and the earl of Cork and Orrery all celebrated her talent. In 1662 she went to Dublin to pursue her husband's claim to certain Irish estates, and there she completed a translation of Corneille's Pompe à, produced with great success in 1665 in the Smock Alley Theatre, and printed in the same year both in Dublin and London. She went to London in March 1664 with a nearly completed translation of Corneille's Horace, but died of smallpox on the 22nd of June. The literary atmosphere of her circle is preserved in the excellent Letters of Orinda to Poliarchus, published by Bernard Lintot in 1705 and 1706. "Poliarchus." (Sir Charles Cotterel) was master of the ceremonies at the court of the Restoration, and afterwards translated the romances of La Calprenède. Mrs Philips had two children, one of whom, Katharine, became the Countess of Oxford and Warwick. She was born at Pembroke. According to Mr Gosse, this lady may have been "Joan Philips," the author of a volume of Female Poems... written by Ephelia, which are in the style of Orinda, and display genuine feeling with very little reserve.

PHILISTINES, the general name for the people of Philistia (Ass. Palaššā, Piliššā; Eg. pr-t-š), a district embracing the rich lowlands on the Mediterranean coast from the neighbourhood of Jerusalem to the mouth of the Jordan. "Philistine," as a term of contempt, hostility or reproach, appears first in English, in a sense equivalent to "the enemy," as early as the beginning of the 17th century, and later as a slang term for a bullfighter or a sheriff's officer, or merely for drunken or vicious people generally. In German universities the townsfolk
of Jaffa (Joppa) to the Egyptian desert south of Gaza (on the subsequent extension of the name in its Greek form Palaestina, see History).

1. Egyptian Evidence.—The name is derived from the Purasati, one of a great confederation from north Syria, Asia Minor and the Levant, which threatened Egypt in the XXth Dynasty. They are not among the hordes enumerated by Rameses II. or Merneptah, but in the eighth year of Rameses III. (c. 1200-1190) the Purasati hold a prominent place in a widespread movement on land and sea. The Syrian states were overwhelmed and the advance upon Egypt seemed irresistible. Rameses, however, collected a large fleet and an army of native troops and mercenaries and claimed decisive victories. The Egyptian monuments depict the flight of the enemy, the heavy ox-carts with their women and children, and the confusion of their ships. But the sequel of the events is not certain. Even if the increasing weakness of the Egyptian Empire did not invite a repetition of the incursion, it could have allowed the survivors to settle down, and about a century later one of the peoples formerly closely allied with the Purasati is found strongly entrenched at Elchat, south of the Red Sea, nearer port of Dyreh, with scant respect for the traditions of the past. That some definite political changes ensued in this age have been inferred on other grounds, and the identification of the Purasati with the Philistines may permit the assumption that the latter succeeded in occupying the district with which they have always been associated.

The Egyptian monuments represent the Purasati with a very distinctive feather head-dress resembling that of the Lyceans and Mycenaenaeans. Their general physiognomy is hardly Cilician or Hittite, but European. Their arms comprise two short swords, a longer spear, a round shield, and they sometimes wear a coat of mail; a curious feature is their tactics of fighting in a circle of protecting shields. The chariots resemble the Hittite with two crossed receptacles for the weapons, but obviously these were not used by the Purasati alone. On archaeological grounds the Purasati have been connected with the people of Keftiu, i.e. Mycenaenae of Crete, although a wider application of this term is not to be excluded.

2. History.—Biblical tradition, too, has recognized the Philistines as immigrants from Caphtor (Amos ii. 7). They appear in the pre-Mosaic age (Gen. xxii. 32, 34, xxvii.), at the Exodus of the Israelites (Ex. xiii. 17, xv. 14), and the invasion of Palestine. They are represented as a confederation of five cities (Ashdod, Ascalon [Ashkelon], Ekron, Gath and Gaza) which remained unconquered (Joshua xiii. 2 seq.), Judges iii. 3; contrast Joshua xv. 45-47, xix. 43). The institution of the Hebrew monarchy (c. 1000 B.C.) follows upon periods of Phœnician oppression (Judges iii. 11, 7, 11, xili. 2-5; see Samson; Eli; Samuel; Saul; David). The subjugation of them is ascribed by the authors Philister; they were "outsiders," the enemies of the chosen people. It is supposed that this use arose in 1600 B.C. or soon after—a "town and gown" row in which a student had been killed and a sermon preached on the text "the Philistines be upon you, Samson" (see Quarterly Review, April 1899, 435, note, quoted in the New English Dictionary). "Philistines" thus became the name of contempt applied by the later inhabitants of these countries, which were considered beneath them in intellect and taste, and was first so used in English by Carlyle, and Matthew Arnold (Essays in Criticism). "Heinrich Heine," (1885) gave the word its modern and its final connotation, as signifying "inaccessible to and impatient of ideas."—[ED.]

1 So the Papyrus first published by W. Golenischeff (Rec. d'Egypte, xxi. 74 sq.), on which see A. Erman, Zeit. f. alt. Sprache, pp. 1-14 (1900); W. M. Müller, Mittel. d. vorderasiatischen Gesell., pp. 14 sqq. (1900); J. H. Breasted, Hist. of Egypt, pp. 513 sqq.; Historical Records, iv. 274 sqq.; H. W. Hogg, in the Theolog. Series i. of the publications of university of Manchester, p. 90 sqq. to Samuel (1 Sam. vii. 13), Saul (xiv. 47), and David (2 Sam. viii. 1; for Solomon see Kings x. 20); but they evidently recovered their independence, and we find that twice within a short time the northern Israelites laid siege to the border fortress of Gibbethon (1 Kings xv. 27, xvi. 15). Although this place has not been identified, it is mentioned in a list of Danite cities with Ajalon, Ekron, Eltekeh and Timnah (Joshua xix. 44, xxi. 23), names of importance for the history. Somewhat later the evidence becomes fuller, and much valuable light is thrown upon the part which the Philistine coast played in the political history of Palestine. Gaza, the most southerly and famous of the Philistine towns, was the terminus of the great caravan-route from Edom and south Arabia, with whose Bedouin it was generally on good terms. It was the "outpost of Africa, the door of Asia" (G. A. Smith), the stepping-off point for the invasion of Egypt, and the fortress which, next in importance to Lachish, barred the maritime road to Phœnicia and Syria. It is necessary to realize Gaza's position and its links with trading centres, since conditions in the comparatively small and half-desert land of Judah depended essentially upon its relations with the Edomites and Arab tribes on the south-east and with the Philistines on the west. Jehoshaphat's supremacy over the Philistines and Arabians (1 Kings xiv. 29), confirmed by the capture of Gaza after the defeat of Asa (1 Kings xxii. 47) is followed by the revolt of Lelannah (near Lachish) and Edom against his son Jehoram (2 Kings viii. 20, 22). The book of Chronicles mentions Philistines and Arabians, and knows of a previous warning by a prophet of Maresiah (east of Lachish; 2 Chron. xx. 37, xxi. 16). In like manner, the conquests of Uzziah over Edom and allied tribes (2 Kings xiv. 22, see 2 Chron. xxvii. 7) and over Gath, Ashdod and Jabinah (ibid. v. 6) find their sequel in the alliance of Samaria and Damascus against Ahaz, when Edom recovered its independence (so read for "Syria" in 2 Kings xvi. 6), and the Philistines attacked Beth-sheanesh, Ajalon, Timnah, &c. (2 Chron. xxvii. 18 seq.). These notices at least represent natural conditions, and the Assyrian inscriptions now are our authority. Tiglath-pileser IV. (734 B.C.) marched down and seized Gaza, removing its gods and goods. Its king Hanun had fled to Muṣṣri, but was pursued and captured; Ascalon,Judah and Edom appear in a list of tributaries. Muṣṣri was entrusted to the care of the Arab tribes (the desert district), but continued to support anti-Assyrian leagues (see below). It is recorded again in 720 (two years after the fall of Samaria) was in alliance with Gaza and north Palestine. Assyria under Sargon defeated the southern confederation at Rapīpī (Raphia on the border of Egypt) and captured Hanun; the victory is evident from the submission of the queen of Aribi (Arabia), the sabaean Itamara, and Muṣṣri. This Muṣṣri appears to have been a district outside the limits of Egypt proper, and although tribes of the Delta may well have been concerned, its relations to Philistia agree with the independent biblical account of the part played previously by Edom and Arab tribes (see Mizraim). But the disturbances continued, and although desert tribes were removed and settled in Samaria in 715, Muṣṣri and Philistia were soon in arms again. Ashdod (see Isa. xx.) and Gath were taken and sacked, the people removed, and fresh colonies were introduced. Judah, Edom and Moab were also involved, but submitted (711 B.C.). Scarcely ten years passed and the whole of Palestine and Syria was again torn with intrigues. Sennacherib (Sargon's successor in 705) marched to the land of the "Hittites," traversed

2 See G. A. Smith, Hist. Geog. of the Holy Land, chs. ix. seq.; and M. A. Meyer, History of the City of Gaza (New York, 1907). For the later history of Gaza, see Index, s.v. Minos; the resemblance between the Minaean of South Arabia and Cretan Minos has afforded grounds for all kinds of speculations, ancient (Pliny vi. 157) and modern.

3 Between the central Judea plateau and the latter lay the "lowlands" (Shephelah), a district open equally to Judeans and Philistines alike.

4 Cf. Gaza and Edom against Judah in Amos i. 6, and, for the part played by Damascus, the later vicissitudes under the Nabataeans (Nepherus, Ant. xiii. 13, 3). It is difficult to date the alliance of Syria and Philistia against Israel in Is. xi. 11 (on the text, see the commentaries).
the coast and, descending from Sidon, took Jaffa, Beth-dagon, Beneberak, Ekron and Timnah (all in the district ascribed to the southern Dan). At Eltekeh (also in Dan) the allies were defeated. Farther south came the turn of Ascalon, Lachish and Libnah; Judah under Hezekiah suffered severely, and its western cities were transferred to the faithful vassals of Ekron, Ashdod and Gaza. The immediate subsequent events are obscure (see further Hezekiah). In the 7th century B.C., Ashdod, Ashdod and Ekron were Assyrian vassals, together with Judah, Moab and Edom—in all, twenty-two kings of the "Hittites"—and the discovery of Assyrian contract-tablets at Gezer (c. 650) may indicate the presence of Assyrian garrisons. But as the Assyrian power declined Egyptian monarchs formed plans of aggrandizement. Herodotus mentions the Scythian invasion and sack of the temple of Aphrodite Urania (Astarte) at Ascalon, also the prolonged siege of Ashdod by Psammetichus, and the occupation of Kadyris (7 B.C.) by Necho (i. 105, ii. 157 sqq., iii. 5). But the Babylonian Empire followed upon traditional lines and thrust back Egypt, and Nabonidus (555 B.C.) claims his vassals as far as Gaza. The Persians took over the realm of their predecessors, and Gaza grew in importance as a seat of international commerce. Nehemiah speaks not of Philistines, but of Ashdodites (iv. 7), speaking an "Ashdodite" dialect (xiii. 24); just as Strabo regards the Jews, the Idumaeans, the Gazans and the Ashdodites as four cognate peoples having the common characteristic of combining agriculture with commerce. In southern Philistia at least, Arabian immigration became more pronounced. In the time of Cambyses Arabs were settled at Jenysos south of Gaza (Herod. iii. 3), and when Alexander marched upon Egypt, Gaza with its army of Arabs and Persians offered a strenuous resistance. Recent discoveries near Tell Sandahannah (or Maarash) have revealed the presence of North Arabian (Edomite) names about the 2nd century B.C.1 On the history of the district see further Jews; Maccabees; Palestine.

Philistine Traditions.—The interdependence of the south Palestinian peoples follows from geographical conditions which are unchangeable, and the fuller light thrown upon the last decades of the 8th century B.C. illuminates the more fragmentary evidence elsewhere.2 Hence the two sieges of the Philistine Gibbethon by the Israelites (above) obviously have some significance for Judean history, but the Judah annals unfortunately afford no help (see Asa). Again, the Aramean attack upon Israel by Hazael of Damascus leads to the capture of Gath (2 Kings xii. 17), and this, together with the statement that he took "the Philistines" from Jehoahaz of Israel (ibid. xii. 22, Lucian's recension), bears upon Judah, but the statements are isolated. Somewhat later, the Assyrian king Adad-nirari IV. claimed tribute from Edom, Philistia and Beth-Omri (the Israelite kingdom); the curious omission of Judah has suggested that it was then included with the second or third of these (see Jews, § 12). The Philistines may finally have had a prominent place in popular tradition, and the story of Isaac and the Philistine Abimelech (Gen. xxvii., cf. xxxi. 32) is of great interest for its unbiased representation of intercourse, enmity, alliance and covenant. But it is important to notice that a parallel story (xx.) is without this distinctively Philistine background, and this variation is significant. One account of the Israelite invasion conceived a conquest of earlier giant inhabitants (Anakim) who survived in Gaza, Gath and Ashdod (Joshua xii. 21 seq. contrast xiii. 3), but were driven out from Hebron by Caleb (Joshua xv. 14, cf. Num. xiii. 22, 28). The Philistines themselves are called the remnant of the Anakim (Jer. xviii. 1, so the Septuagint), or as Caphtorim replace the earlier Avvim (Deut. ii. 23, see Joshua xiii. 3). Samuel's great defeat of the Philistines leads to "peace between Israel and the Amorites" (1 Sam. vii. 14); and the migration of the Danites is placed after Samson's conflicts with the Philistines (Judges xviii. seq.), or is due to the pressure of Amorites (i. 34). Even in David's fights with the Philistines in Judah, Jerusalem is Jebusite, neighbouring non-Israelite cities are Hivite or Amorite (Joshua ix. 7, 2 Sam. xii. 2), and his strange adversaries find a close parallel in the semi-mythical sons of Anak (2 Sam. xxi. 16, 18, 20, 22). This fluctuation, due partly to the different circles in which the biblical narratives took shape, and partly to definite reshaping of the traditions of the past, seriously complicates all attempts to combine the early history of Israel with the external evidence. The history of the Philistine district goes back long before the time of the Purasati (c. 1200 B.C.), and if the references to Philistines in pre-Mosaic times are treated as anachronisms, those which can be applied to the 12th—11th century do not at once acquire an historical value.3 The references of the time of the Exodus, the Invasion and the "Judges"—whatever chronological scheme be adopted—must be taken in connexion with a careful examination of all the evidence. It is inherently not improbable that a recollection has been preserved of Philistine oppressions in the 11th century, but it is extremely difficult to sketch any adequate sequence of events, and among the conflicting traditions are situations equally applicable to later periods of hostility. Biblical history has presented its own views of the Israelite and Judean monarchies; Israel has its enemies who come pouring forth from the south (1 Sam. xiii. 17, 18), while the founder of the Judaean dynasty has intimate relations with a Philistine king Achish (or Abimelech, Ps. xxxvii.), or, from another point of view, clears the district of a prehistoric race of giants. In the stories of Samson and Samuel, the Philistines are located in the maritime plain, whereas, in the oldest traceable account of Saul's rise (apparently shortly before 1000 B.C.) they hold Israel (1 Sam. ix. 16, xii. 3 seq., xiv. 1, 11). But there is a historical continuity between the two situations, and the immediate predecessor of Saul and Jonathan is lost. The biblical evidence does not favour any continued Philistine domination since the time of Rameses III., who indeed, later in his reign, made an expedition, not against the Purasati, but into North Syria, and, as appears from the Papyrus Harris, restored Egyptian supremacy over Palestine and Syria. Upon the (incomplete) external evidence and upon a careful criticism of the biblical history of this period, and not upon any promiscuous combination of the two sources, must depend the value of the plausible though broad reconstructions which have been proposed.4

Considerable stress is often laid upon Goliath's armour of bronze and his iron weapon, but even David himself has heimet, sword and coat-of-mail at his disposal (1 Sam. xvii.), and suits of armour had already been taken from Mesopotamia by Tethmosis III. Chariots of iron are ascribed to the Canaanites (Joshua xii. 18), and Judges xxx. 4; and iron references to iron are treated as unhistorical (Gen. iv. 22, Num. xxxii. 22, xxv. 16, Deut. iv. 20, vii. 9, xiv. 1, xv. 2, xvii. 48, xxxii., 23; Joshua vi. 19, 24) Goliath's iron spear-head must be judged together with the whole narrative in the light of a consistent historical criticism.5

1 The inhabitants of Ascalon besieged by Rameses II. are represented as Hittites. For an attempt to treat the pre-Mosaic references, as see A. Noordzij, De Filistijnjen (Kampen, 1905).

2 See on these, W. M. Müller, Miillerii, d. vorseraisal. Geiss. p. 35; F. Delitzsch, Geschichte d. vorderasiat. Alterth., 1720 seq. and cf. H. W. Hogg, op. cit. p. 91. For the suggestion that the "Philistines" have in certain cases taken the place of another ethnic, see S. A. Cook, Crit. Notes on O. T. History, pp. 43 seq., 127 seq., 111 seq. 126 seq., ed. cf. another view of T. K. Cheyne, Decline and Fall of Kingdom of Judah (1908), pp. xx. seq.

3 The introduction of iron has been ascribed to about 1000 B.C. (Macalister, Quart. Stutum, p. 321 [1905], as against p. 122 [1904]; H. Vincent, Camaan d'apres l'exploration recente, p. 225 seq.). I need hardly be said that the height and might of Goliath must be regarded in the same way as Num. xxxii. 32; Deut. ii. 11. The men of the heroic age are giants, as were the 'Ad and Thamud to the later Arabs.
PHILISTUS

4. Conclusions.—The Philistines appear in the Old Testament as a Semitic or at least a thoroughly Semitized people. Their proper names show that before and even during the Persian age their languages differed only dialectically from Hebrew. Among the exceptions must be reckoned Achish (Sept. Ἀχίς), with which has been compared Ikau, a king of Ekron (6th century) and the “Keftian” name Akasha of the XXth Egyptian dynasty. Names in -ath (Goliath; Ahuzzath, Gen. xxvi.) are not restricted to Philistines, and Phicol (ibid.) is too obscure to serve as evidence. The religion is not novel. The male god Dagon has his partner Astare (q.v.), and Baal-zebub, a famous oracle of Ekron (2 Kings i.) finds a parallel in the local baals of Palestine.1 Even when the region seems to be completely Hellenized after the Persian age, it is not so certain that Greek culture pervaded all classes.2 G. F. Moore, Ency. Bib. col. 3726, although a certain amount of foreign influence probably made itself felt upon the coast-towns at all times. The use of the term ἀλλάξοντα in Maccabean and later writings (cf. the contemptuous hatred of Ben Sira, Ecclesiasticus i. 26, and the author of Jubilees xxiv. 30 sqq.) correctly expresses the conditions of the Greek age and the Maccabean wars, and naturally any allusion to the situations of many centuries previously is quite unnecessary. Similarly, the biblical evidence represents the traditions in the form which they had reached in the writer’s time, the true date of which is often uncertain. Antagonism between Philistines and Israelites was not a persisting feature, and, although the former are styled “uncircumcised” (chiefly in the stories in the book of Samuel), the term gained new force when the expulsion of uncircumcised aliens from the sanctuary of Jerusalem was proclaimed in the writings ascribed to Ezekiel (ch. xlvii.).

In fact the question arises whether the history of the Philistines is not that of a territorial designation, rather than that of the lineal descendants of the Purasati, who, if one of the peoples who took part in the events of the XXth Dynasty, may well have bequeathed their name. The Mediterranean coast-land was always exposed to incursions of aliens, and when Carians appear as royal and temple guards at Jerusalem (2 Kings xi. 4), it is sufficient to recall old Greek traditions of a Carian sea-power and relations between Philistia and Greek lands.3 Even the presence of Carians and Ionians in the time of Psammetichus I. may be assumed, and when these are planted at Daphne it is possible that Psammetichus III. also is Phoenician (Jer. xxvi. 20–27).4 The Philistine colony (viz. Tahtanhes, Jer. xxiii. seq.) appeared after the 15th–14th centuries, now illuminated by the Amarna tablets, their own history is perhaps earlier.5 But there is no reason at present to believe that their entrance caused any break in the archaeological history. The apparently “Aegean” influence which enters into the general “Amarna” period seems to begin before the age of the Amarna tablets (at Lachish), and it passes gradually into later phases contemporary with the

---

1 See further, F. Schwall, Zeit. Wissens. Theol. xxxiv. 103-108. A few Hebrew words have been regarded as Philistine loan-words, so especially F. Moortgat, “Phoenaica,” R.A.S. Proc. 1909, and seven (ςεπανος) the title applied to the five lords of the Philistine confederation; seven otherwise means “axle,” and may have been applied metaphorically like the Arab. ψαλτ (W. R. Smith). On the other hand, a common origin in Asia Minor is also possible for these words.

2 In the prophetic writings the Philistines are denominated (with Ammon, Moab and Edom) for their vengeance upon Judah (Ezek. xxv. 15–17). With Tyre and Sidon they are condemned for plundering Judah, and for kidnapping its children to sell to the Greeks (Joel iii. 4–8; cf. Amos i. 6–12; 1 Macc. iii. 41). They are threatened with a foe from the north (Jer. xxv. 20; Isa. xiv. 29–31; see PHAINAN), as also is Phoenicia (Jer. xxxii. 23–24); but they depend (cf. Zech. ix. 3–8). Judah is promised reprisals (Zeph. ii. 7; Obad. 16), and a remnant of the Philistines may become worshippers of Yahweh (Zech. ix. 7). The historical backgrounds of these passages are based.

3 See J. L. Myres, Journal of Hellenic Studies, xxvi. 84 sqq. (1906); especially pp. 108, 127 sqq.

4 This is suggested by the recent discovery at Phaestos in Crete of a disk with evidence of a Philistine clientele (see J. J. Evans, Scripta Minos (Oxford, 1909), pp. 22 sqq.; E. Meyer, Sitzungsberichte of the Berlin Academy for the 21st of October 1909.)

Israelite monarchy. There is a fairly continuous intercourse with external culture (Cypriote, early and late Greek), and, if Gath be identified with Tel es-Safi, Blasis and Macalister, who excavated it, found no trace of any interruption in its history. Only at Gezer—perhaps Philistine, 2 Sam. v. 25—there has been found evidence for a strange race with several distinctive features. Bricked vault tombs were discovered containing bodies oustretched (not contracted); the deposits were of an unusually fine character and comprised silver, alabaster and even iron. The culture appears to find Carian and Lydian parallels, and has been ascribed provisionally to the 13th–10th centuries. So far, however, of the cities lying within or immediately exposed to Philistine influence, the discoveries at Gezer are unique.

According to the biblical traditions the Philistines are the remnant of Caphtor (Jer. xxvii. 4, Amos ix. 7), and the Caphtôrîm drove out the aboriginal Avva from Gaza and district, as the Horites and Rephaim were displaced by Edom and Ammon (Deut. ii. 23). These Caphtôrîm, together with Ludim (Lydians) and other petty peoples, apparently of the Delta, are once reckoned to Egypt (Gen. x. 14).6 By Caphtor the Septuagint has sometimes understood Cappadocia, which indeed may be valid for its age, but the name is to be identified with the Egyptian K(a)ptar, which in later Ptolemaic times seems to mean Phoenicia, although Kefih had another connotation. The Cherethis, associated with the Philistine district (1 Sam. xxx. 14, 16, Ezek. xxv. 16, Zeph. ii. 5 seq.), are sometimes recognized by the Septuagint as Cretans, and, with the Pelethites (often taken to be a rhyming form of Philistines), they form part of the North Coast of Judaeans (2 Sam. xviii. 18, xx. 7, 1 Kings i. 38, 44; to 2 Sam. xx. 23 the Hebrew text has Carites). However adequate these identifications may seem, the persistence of an independent clan or tribe of Cherethis-Cretans to the close of the 7th century would imply an unbroken chain of nearly six hundred years, unless, as is inherently more probable, later immigrations had occurred within the interval. But upon the ethnological relations either of the south Palestinian coast or of the Delta it would be unsafe to dogmatize. So far as can be ascertained, then, the first mention of the Philistines belongs to an age of disturbance and change in connexion with movements in Asia Minor. Archaeological evidence for their influence has indeed been adduced,7 but it is certain that some account must be taken also of the influence which the Philistines exercised in the Ionian world for, whether from the Levant or from the north, were not confined to the age of Rameses III. alone, and the biblical evidence, especially, while possibly preserving some recollection of the invasion of the Purasati, is in every case late and may be shaped by later historical vicissitudes. It is impossible that Palestine should have remained untouched by the external movements in connexion with the Delta, the Levant and Asia Minor, and it is possible that the course of internal history in the age immediately before and after 1000 B.C. ran upon lines different from the detailed popular religious traditions which the biblical historians have employed. (See further PALESTINE: History.)

For older studies, see F. Hitzig, Uebersicht der Philister (1845), with the theory of the Pelagian origin of the Philistines; K. Stark, Dionysus u. d. philist. Käste (1852), and (with special reference to earlier theories) W. Robertson Smith’s art. in Ency. Brit., 9th ed.

PHILISTUS, Greek historian of Sicily, was born at Syracuse about the beginning of the Peloponnesian War (432 B.C.). He was a faithful supporter of the elder Dioniysus, and commander

---

7 v. 13 seq. may be a secondary addition “written from specially intimate acquaintance with the (later?) Egyptian geography” (J. Skinner, Genesis, p. 214).

8 See D. G. Hogarth, Ionia and the East, pp. 28 sqq. (Oxford, 1909); Evans, Scripta Minos, pp. 77 sqq.
of the citadel. In 386 he excited the jealousy of the tyrant by secretly marrying his niece, and was sent into banishment. He settled at Thriss, but afterwards removed to Adria, where he remained until the death of Dionysus (366). He was then recalled by the younger Dionysus, whom he persuaded to dismiss Plato and Dion. When Dion set sail from Zancynthus with the object of liberating Syracuse from the tyrannis, Philius was entrusted with the command of the fleet, but he was defeated and put to death (356). During his stay at Adria, Philius occupied himself with the composition of his Συζητάω, a history of Sicily in eleven books. The first part (bkss. i.–vii.) comprised the history of the island from the earliest times to the capture of Agrigentum by the Carthaginians (406); the second, the history of the elder and the younger Dionysus (down to 363). From this point the work was carried on by Philius's fellow countryman Athanas. Cicero (ad. Q. Fr. ii. 13), who had a high opinion of his work, calls him the miniaturist Τυχυδίδης ("pussillus Thucydidēs"). He was admitted by the Alexandrian critics into the canon of historiographers, and his work was highly valued by Alexander the Great.

Müller, Fragmenta historiicorum Graecorum, vol. i. (1841); C. Wachsmuth, Einleitung in das Werk des Thucydidēs. In: Geschichte der Geschichtsquellen, E. Adam, 3rd edn. (1843); A. Holm, Geschichte Siciliens im Altert. (1870–1898).

PHILLAU, a town of British India, in Jullundur district, Punjab, on the north bank of the river Sutlej, 8 m. N. of Ludhiana. Pop. (1901), 69,686. Founded by the Mogul emperor Shah Jahan, it was long of importance as commanding the crossing of the Sutlej. At the Mutiny in 1857 the fort contained the siege train, which was sent safely to Delhi; but the sepoys regiment in the cantonment shortly afterwards mutinied and escaped. The fort is now occupied by the police training school and the central bureau of the criminal identification department.

PHILLMORE, Sir Robert Joseph (1810–1885), English judge, third son of a well-known ecclesiastical lawyer, Dr. Joseph Phillimore, was born at Whitehall on the 5th of November 1810. Educated at Westminster and Christ Church, Oxford, where a life-long friendship with W. E. Gladstone began, his first appointment was to a clerkship in the board of control, where he remained from 1832 to 1835. Admitted as an advocate at Doctors' Commons in 1839, he was called to the bar at the Middle Temple in 1841, and rose very rapidly in his profession. He was engaged as counsel in almost every case of importance that came before the admiralty, probate or divorce courts, and became successively master of faculties, commissary of the deans and chapters of St. Paul's and Westminster, official of the archdeaconries of Middlesex and London, and chancellor of the dioceses of Chichester and Salisbury. In 1853 he entered parliament as member for Tavistock. A moderate in politics, his energies were devoted to non-party measures, and in 1854 he introduced the bill for allowing viva voice evidence in the ecclesiastical courts. He sat for Tavistock until 1857, when he offered himself as a candidate for Coventry, but was defeated. At the same time he was appointed judge of the Chancery Court in 1857, Queen's Counsel in 1858, and advocate-general in admiralty in 1862, and succeeded Dr. Stephen Lushington (1782–1873) as judge of the court of arches five years later. Here his care, patience and courtesy, combined with unusual lucidity of expression, won general respect. In 1875, in accordance with the Public Worship Regulation Act, he resigned, and was succeeded by Lord Penzance. When the Judicature Act came into force the powers of the admiralty court were transferred to the High Court of Justice, and Sir Robert Phillimore was therefore the last judge of the historic court of the lord high admirals of England. He continued to sit as judge for the new admiralty, probate and divorce division until 1883, when he resigned. He wrote Ecclesiastical Law of the Church of England, a book which still holds its ground, Commentaries on International Law, and a translation of Lessing's Laocoon. He married, in 1844, Charlotte Anne, daughter of John Denison of Ossington Hall, Newark. He was knighted in 1862, and created a baronet in 1881. He died at Shiplake, near Henley-on-Thames, on the 4th of February 1885. His eldest son, Sir Walter G. F. Phillimore (b. 1845), also distinguished as an authority on ecclesiastical and admiralty law, became in 1897 a judge of the high court.

PHILLIP, John (1817–1867), Scottish painter, was born at Aberdeen, Scotland, on the 19th of April 1817. His father, an old soldier, was in the service of the Prince of Wales, and the son became an errand-boy to a tinsmith, and was then apprenticed to a painter and glazier. Having received some technical instruction from a local artist named William Mercer, he began, at the age of about fifteen, to paint portraits. In 1834 he made a very brief visit to London. About this time he became assistant to James Forbes, an Aberdeen portrait-painter. He had already gained a valuable patron. Having been sent to repair a window in the house of Major P. L. Gordon, his interest in the works of art in the house attracted the attention of their owner. Gordon brought the young artist under the notice of Lord Panmure, who in 1836 sent him to London, promising to bear the cost of his art education. At first Philip was placed under T. M. Joy, but he soon entered the schools of the Royal Academy. In 1839 he figured for the first time in the royal academy exhibition with a portrait and a landscape, and in the following year he was represented by a more ambitious picture of "Tasso in Disguise relating his Persecutions to his Sister." For the next ten years he supported himself mainly by portraiture and by painting subjects of national incident, such as "Presbyterian Catechizing," "Baptism in Scotland," and the "Spacewife." His productions at this period, as well as his earlier subject-pictures, are reminiscent of the practice and methods of Wilkie and the Scottish genre-painters of his time. In 1851 his health showed signs of delicacy, and he went to Spain in search of a warmer climate. He was brought face to face for the first time with the brilliant sunshine and the splendid colour of the south, and it was in coping with these that he first manifested his artistic individuality and finally displayed his full powers. In the "Letter-writer of Seville" (1854), commissioned by Queen Victoria at the suggestion of Sir Edwin Landseer, the artist is struggling with new difficulties in the portrayal of unwonted splendours of colour and light. In 1857 Philip was elected an associate of the Royal Academy, and in 1859 a full member. In 1855 and in 1860 further visits to Spain were made, and in each case the painter returned with fresh materials to be embodied with increasing power and subtlety in the long series of works which won for him the title of "Spanish Phillip." His highest point of execution is probably reached in "La Gloria" (1864) and a smaller single-figure painting of the same period entitled "El Cigarillo." These Spanish subjects were varied in 1860 by a rendering of the marriage of the princess royal with the crown prince of Prussia, executed by command of the queen, and in 1863 by a picture of the House of Commons. During his last visit to Spain Philip occupied himself in a careful study of the art of Velázquez, and the copies which he made fetched large prices, having been secured by the royal academies and the royal Scottish academies. The year before his death he visited Italy and devoted attention to the works of Titian. The results of this study of the old masters are visible in such works as "La Loteria Nacional," left uncompleted at his death. During this period he resided much in the Highlands, and seemed to be returning to his first love for Scottish subjects, painting several national scenes, and planning others that were never completed. He died in London on the 27th of February 1867.

His works were collected in the International Exhibition of 1873, and many of them are engraved by T. Oldham Barlow. In addition to the paintings already specified the following are among the most important: "Life and Death among the Gipsies of Sicily" (1851), "El Paseo" (1855), "Collection of the Offertory in a Scotch Kirk" (1855), "A Gipsy Water-carrier in Seville" (1855), "The Prayer of Faith shall save the Sick" (1855), "The Dying Contrabandist" (1856), "The Priest of Seville" (1859), "Early Career of Murillo" (1865), "A Chat round the Brasero" (1866).

PHILLIPS, Adelaide (1833–1882), American contralto singer, was born at Stratford-on-Avon, England, her family emigrating to America in 1840. Her mother taught dancing,
and Adelaide began a career on the Boston stage at ten years old. But in 1850 her talent for singing became evident, and through her voice and looks she soon was known in London and other English cities. In 1852 she returned to America an accomplished vocalist; and for many years she was the leading American contralto, equally successful in oratorio and on the concert platform. She died at Carlsbad on the 3rd of October 1882.

PHILLIPS, EDWARD (1630-1696), English author, son of Edward Phillips of the crown office in chancery, and his wife Anne, only sister of John Milton, the poet, was born in August 1630 in the Strand, London. His father died in 1641, and Anne Phillips eventually married her husband’s successor in the crown office, Thomas Agar. Edward Phillips and his younger brother, John, were educated by Milton. Edward entered Magdalen Hall, Oxford, in November 1650, but left the university in 1651 to be a bookseller’s clerk in London. Although he entirely differred from Milton in his religious and political views, and seems, to judge from the free character of his Mysteries of Love and Eloquence (1658), to have undergone a certain revival from his former beliefs, he remained on affectionate terms with his uncle to the end. He was tutor to the son of John Evelyn, the diarist, from 1663 to 1672 at Sayes Court, near Deptford, and in 1677-1679 in the family of Henry Bennet, earl of Arlington. The date of his death is unknown but his last book is dated 1696.

His most important work is Theatrum poetarum (1678), a list of the chief poets of all ages and countries, but principally of the English poets, with short critical notes and a preface Discourse of the Poets and Poetry, which has usually been traced to Milton’s hand. He also wrote A New World in Words, or a General Dictionary (1658), which went through many editions; a new edition of Baker’s Chronicle, of which the section on the period from 1650 to 1668 was written by himself from the royalist standpoint; a supplement (1676) to John Speed’s Theatre of Great Britain; and in 1684 Enchiridion linguae latinae, said to have been taken chiefly from notes prepared by Milton. Aubrey states that all Milton’s papers came into Phillips’s hands, and in 1694 he published a translation of his Letters of State with a valuable memoir.

His brother, JOHN PHILLIPS (1621-1706), in 1652 published a Latin reply to the anonymous attack on Milton entitled Pro Rege et populo anglicano. He appears to have acted as unofficial secretary to Milton, but, disappointed of regular political employment, and chafing against the discipline he was under, he published in 1655 a bitter attack on Puritanism entitled A Satyr against Hypocrites (1655). In 1656 he was summoned before the privy council for his share in a book of licentious poems, Sportive Wit, which was suppressed by the authorities but almost immediately replaced by a similar collection, Wit and Drollery. In Monition (1660) he ridiculed the astrological almanacs of William Lilly. Two other skits of this name, in 1661 and 1662, also full of coarse royalist wit, were probably by another hand. In 1678 he supported the project of engravings for Observations, writing on his behalf, says Wood, “many lies and villanies.”

Dr Oates’s Narrative of the Popish Plot indicated was the first of these tracts. He began a monthly historical review in 1688 entitled Modern History or a Monthly Account of all Considerable Occurrences, Civil, Ecclesiastical and Military, followed in 1690 by The Present State of Europe, or a Historical and Political Mery. The work was supplemented by a preliminary volume giving a history of events from 1688. He executed many translations from the French, and a version (1687) of Don Quixote.

An extended, but by no means friendly, account of the brothers is given by Wood, Athen Oxonienses, ed. Bliss, iv. 704 seq.), where a long note on the subject is devoted to a refutation of William Godwin’s Lives of Edward and John Phillips (1815), with which is reprinted Edward Phillips’s Life of John Milton.

PHILLIPS, JOHN (1800-1874), English geologist, was born on the 23rd of December 1800 at Marden in Wiltshire. His father belonged to an old Welsh family, but settled in England as an officer of excise and married the sister of William Smith, the “Father of English Geology.” Both parents dying when he was a child, Phillips came under the charge of his uncle; and after being educated at various schools, he accompanied Smith on his wanderings in connexion with his geological maps.

In the spring of 1845 Smith went to York to deliver a course of lectures on geology, and his nephew accompanied him. Phillips accepted engagements to give similar courses in various parts of England: he also undertook, as in the principal Yorkshire towns to arrange their museums and give courses of lectures on the collections contained therein. York became his residence, where he obtained, in 1825, the situation of keeper of the Yorkshire museum and secretary of the Yorkshire Philosophical Society. From that centre he extended his operations to towns beyond the county; and in 1831 he included University College, London, in the sphere of his activity. In that year the British Association for the Advancement of Science was founded at York, and Phillips was one of the active minds who organized its machinery. He became in 1832 the first assistant secretary, a post which he held until 1859. In 1834 he accepted the professorship of geology at King’s College, London, but retained his post at York. In 1834 he was elected F.R.S.; in later years he received hon. degrees of L.L.D. from Dublin and Cambridge, and D.C.L. from Oxford; while in 1845 he was awarded the Wollaston Medal by the Geological Society of London. In 1840 he resigned his charge of the York museum and was appointed on the staff of the Geological Survey of Great Britain under De la Beche. He spent some time in studying the Palaeozoic fossils of Devon, Cornwall and West Somerset, of which he published a descriptive memoir (1841); and he made a detailed survey of the region of the Malvern Hills, of which he prepared the elaborate account that appears in vol. ii. of the Memoirs of the Survey (1848). In 1844 he became professor of geology in the university of Dublin. Nine years later, on the death of H. E. Strickland, who had acted as substitute for Dean Buckland in the readership of geology in the university of Oxford, Phillips succeeded to the post of deputy, and at the dean’s death in 1856 became himself reader, a post which he held to the time of his death. During his residence in Oxford he took a leading part in the foundation and arrangement of the new museum erected in 1859 (see his Notices of Rocks and Fossils in the University Museum, 1863; and The Oxford Museum, by H. W. Acland and J. Ruskin, 1859; reprinted with additions 1893). Phillips was also keeper of the Ashmolean museum (1854-1871). In 1859-1860 he was president of the Geological Society of London, and in 1865 president of the British Association. He dined at All Souls College on the 23rd of April 1874, but on leaving him he slipped and fell down a flight of stone stairs, and died on the following day.

From the time he wrote his first paper “On the Direction of the Dilluvial Currents in Yorkshire” (1827), down to the last days of his life, Phillips continued a constant contributor to the literature of science. The pages of the Philosophical Magazine, the Journal of the Geological Society, and the Quarterly Magazine of Natural Philosophy contain valuable essays by him. He was also the author of numerous separate works, which were of great benefit in extending a sound knowledge of geology. Among these may be specially mentioned: Illustrations of the Geology of Yorkshire (in two parts, 1829 and 1833), ed. of pt. i. in 1838, 3rd ed., by R. Etheridge, in 1875); A Treatise on Geology (1837-1839); Memoirs of William Smith (1844); The Rivers, Mountains and Sea-Coast of Yorkshire (1853); Manual of Geology, Practical and Theoretical (1855); Life of William Smith (1856); Geology of Oxford and the Valley of the Thames (1871). To these should be added his Monograph of British Belemnitidae (1865), for the Palaeontographical Society, and his geological map of the British Isles (1873).

See Biographical Memoir, with portrait, in Geol. Mag. (July 1870).

PHILLIPS, SAMUEL (1814-1894), English journalist, the son of a Jewish tradesman in London, was born on the 28th of December 1814. He was educated at University College, London, and then at Göttingen. Having renounced the Jewish faith, he returned to England and entered Sidney Sussex College, Cambridge, with the design of taking orders. His father’s death, however, prevented this, and in 1841 he took to literary work. He wrote a novel, Caleb Stukely (1862), and other tales, and about 1845 began a connexion with The Times as literary critic. In the following year he purchased the John Bull newspaper, and edited it for a year. Two volumes of his Essays from The Times appeared in 1852 and 1854. Phillips took an active part in the formation of the Crystal Palace Company, and wrote their descriptive guides. In 1852 the university of Göttingen
PHILLIPS, S.—PHILLIPS, WENDELL

407

conferr'd upon him the honorary degree of LL.D. He died at Brighton on the 14th of October 1854.

PHILLIPS, STEPHEN (1818—1884), British poet and dramatist, was born on the 28th of July 1868 at Somerton near Oxford, the son of the Rev. Stephen Phillips, precentor of Peterborough Cathedral. He was educated at Stratford and Peterborough Grammar Schools, and entered Queen's College, Cambridge; but during his first term at Cambridge, when F. R. Benson's dramatic company visited the town, he joined it, and for six years played various small parts. In 1890 a slender volume of verse was published at Oxford with the title Primavera, which contained contributions by him and by his cousin Laurence Binyon and others. In 1894 he published Ereumus, a long poem of loose structure in blank verse of a philosophical complexion. In 1896 appeared Christ in Hades, forming with a few other short pieces one of the slim paper-covered volumes of Elkin Mathews's "Shilling Garland." This poem arrested the attention of watchful critics of poetry, and when it was followed by a collection of Poems in 1897 the writer's position as a new poet of exceptional gifts was generally recognized. This volume contained a new edition of "Christ in Hades," together with "Marchesa," The Woman with the Dead Soul, "The Wife" and shorter pieces, including "Michael." The poem Colossus, offered for the best new book of its year, ran through half a dozen editions in two years, and established Mr Phillips's rank as poet, which was sustained by the publication in the Nineteenth Century in 1898 of his poem "Endymion." George Alexander, the actor-manager, moved perhaps by a certain clamour among the critics for a literary drama, then commissioned Mr Phillips to write him a play, the result being Paolo and Francesca (1900), a drama founded on Dante's famous episode. Encouraged by the great success of the drama in its literary form, Mr Alexander produced the piece at the St James's Theatre in the course of 1901. In the meantime, Mr Phillips's next play, Herod: a Tragedy, had been produced by Beersbom Tree on the 31st of October 1900, and was published as a book in 1901; Ulysses, also produced by Beersbom Tree, was published in 1902; The Sin of David, a drama on the story of David and Bathsheba, translated into the times and terms of Cromwellian England, was published in 1904; and Nero, produced by Beersbom Tree, was produced in 1903. In the plays of the revised method of Shakespeare and the Elizabethans, to revitalize the method of Greek drama. Paolo and Francesca (which admitted certainly one scene on an Elizabethan model) was the most successful, the subject being best adapted to the lyrical cast of Mr Phillips's poetical temperament; but all contained fine poetry, skilfully stage-managed by a writer who had practical experience of stage craft.

For bibliography up to July 1903, see English Illustrated Magazine new series, vol. xvi. p. 442.

PHILLIPS, THOMAS (1770-1843), English portrait and subject painter, was born at Dudley in Warwickshire on the 18th of October 1770. Having acquired the art of painting at Birmingham, he visited London in 1790 with an intention of going to Beersbom, West. He spent a year in employment on the windows in St George's Chapel at Windsor. At first Mr Phillips painted a view of Windsor Castle, and in the next two years he exhibited the "Death of Talbot, Earl of Shrewsbury, at the Battle of Castillon," "Ruth and Naomi," "Elijah restoring the Widow's Son," "Cupid disarmed by Euphrosyne," and other pictures. After 1796, however, he mainly confined himself to portrait-painting. It was not long before he became the chosen painter of men of genius and talent, notwithstanding the rivalry of Hoppner, Owen, Jackson and Lawrence; and he left behind portraits of nearly all the illustrious characters of his day. In 1804 he was elected associate and in 1808 member of the Royal Academy. In 1824 Phillips succeeded Fuseli as professor of painting to the Royal Academy, and office which he held till 1832. During this period he delivered ten Lectures on the History and Principles of Painting, which were published in 1833. He died on the 20th of April 1845.

PHILLIPS, WENDELL (1811-1884), American orator and reformer, was born in Boston on the 20th of November 1811. His father, John Phillips (1770-1823), a man of wealth and reformer, graduated at Harvard College in 1788, and became successively "town advocate and public prosecutor," and in 1822 first mayor of Boston, then recently made into a city. Wendell Phillips himself attended the public Latin school, entered Harvard College before he was sixteen, and graduated in 1831 in the same class with the historian John Lathrop Motley. He graduated at the Harvard law school in 1834, and was admitted to the bar in Boston. He soon came under the influence of the anti-slavery movement, witnessing in 1835 the mobbing, in Boston, of William Lloyd Garrison. On the 8th of December 1837 a meeting was held at Faneuil Hall to express the sentiments of the people on the murder of Elijah P. Lovejoy, at Alton, Illinois, for defending his press from a pro-slavery mob. In the same year Mr Phillips was made in opposition to its general current by James T. Austin (1784-1870), attorney-general of the state, who said that Lovejoy had died "as the fool dieth," and compared his murderers to the men who threw the tea into Boston harbour just before the War of Independence. The speech seemed likely to divide the audience, when Wendell Phillips took the platform. "When I heard," he said, "the gentleman lay down principles which placed the murderers of Alton side by side with Otis and Hancock, with Quincy and Adams, I thought these pictured lips (pointing to their portraits) would have broken into voice to rebuke the recreant American, the slanderer of the dead." This appeal not merely determined the sentiment of the meeting, it gave Wendell Phillips his first fame and determined his career. Although loving his profession, and this especially for the opening it gave in the direction of public life, he practically stepped outside the sphere dearest to young Americans, and lived henceforth the life of an agitator, or, like his father, that of a "public prosecutor." Accepting unhesitatingly the Garrisons' methods of war, he became a Glauber and disunionist, he lived essentially a platform life, interested in a variety of subjects, but first and chiefly an abolitionist. In 1855, however, after the Civil War, he broke with Garrison over the question of discontinuing the Anti-Slavery Society, and from that date until the society was disbanded in 1870 he, instead of Garrison, was its president. He was not, moreover, like his great leader, a non-resistant, nor was he, on the other hand, like John Brown, borne on by irresistible necessity to overt action. Nor did he find, like his fellow-worker, Theodore Parker, the leisure to keep up his scholarship and lead in part the life of a student. Early study and travel had indeed furnished him with abundant material for rhetorical illustration; and he was also a great reader of newspapers, but he used to say that he knew in his whole life but one thing thoroughly, namely, the history of the English Civil War, and there were few occasions when he could not draw from it the needful illustration. His style of eloquence was direct and brilliant, but eminently self-controlled. He often surprised his hearers by the quietness of his manner and the command of his voice which turned out most brilliant and most irresistible were the close. He may be said to have introduced the direct and colloquial manner upon the American public platform, as distinct from the highly elaborated and often ornate style which had been established by Edward Everett; nor has there ever been a reversion since his day to the more artificial method. He was capable at times, nevertheless, of highly sonorous periods with superb climaxes; yet his favourite style was the conversational. His logic, while never obtruded, was rarely at fault; but he loved the flash of the rapier, and
PHILLIPS, W.—PHILLPOTTS

PHILLIPSBURG, a town of Warren county, New Jersey, U.S.A., on the Delaware river, opposite Easton, Pennsylvania, and about 51 m. N.N.W. of Trenton, N.J. Pop. (1900) 10,052, of whom 990 were foreign-born; (1910 U.S. census) 13,903. Served by the Central of New Jersey and other railways, the town is situated in the river bottom and on a bluff which commands beautiful views. The river is spanned here by several bridges. The town has railway shops and various manufactures. In 1905 the value of the factory products was $6,684,173 (45-8% more than in 1900). Phillipsburg was settled about 1750. It was only a straggling village when the Morris Banking and Canal Company was chartered in 1824, but its growth was accelerated by the canal (no longer used), by the establishment in 1848 of an iron furnace, and by the completion of the Central Railroad of New Jersey to this point in 1852; the town was incorporated in 1861.

PHILLPITSE, a mineral of the zeolite group; a hydrated potassium, calcium and aluminium silicate, approximating to (K₂, Ca)₃Al₆(AlO₂)₄(SiO₂)₄·9H₂O. It varies somewhat in composition, and a variety ("pseudophillite") containing rather less silica has the formula (K₂, Ca)₃Al₆(SiO₂)₄·4H₂O. Crystals are monoclinic, but only complex cruciform twins are known, these being exactly like twins of harmotome (q.v.). Crystals of phillipite are, however, usually smaller and more transparent and glassy than those of harmotome. Spherical groups with a radially fibrous structure and bristled with crystals on the surface are not uncommon. The hardness is 4½, and the specific gravity 2-2. The species was established by A. Lévy in 1825 and named after William Phillips. French authors use the name christianite (after Christian VIII of Denmark), given by A. Des Cloizeaux in 1847.

Phillipite is a mineral of secondary origin, and occurs with other zeolites in the amygduolated cavities of basic volcanic rocks: e.g. in the basalt of the Giant's Causeway in County Antrim, and near Melbourne in Victoria; and in lencitite near Rome. Small crystals of recent formation have been observed in the masonry of the hot baths at Plombières and Bourbunnes-Bains, in France. Minute spherical aggregates embedded in red clay were dredged by the "Challenger" from the bottom of the Central Pacific, where they had been formed by the decomposition of lava.

(L. J. S.)

PHILLPOTTS, HENRY (1778-1869), English bishop, was born at Bridgewater on the 6th of May 1778, and was educated at Gloucester College school and at Corpus Christi College, Oxford. He became a fellow of Magdalen College, Oxford, in 1795, took orders in 1802, and was select university preacher in 1804. In 1805 he received the living of Stanton-le-Street, Durham, and in addition was appointed to Bishop Middleham, Durham, in the succeeding year. For twenty years he was chaplain to the Shute Barrington, bishop of Durham. He was appointed vicar of Gateshead in 1808, prebendary of Durham in 1809, and vicar of St Margaret, Durham, in 1810. After holding the rich living of Stanhope, Durham from 1820, and the deanery of Chester from 1828, he was consecrated bishop of Exeter in 1831, holding with the see a residuary canonry at Durham. His published works include numerous speeches and pamphlets, including those connected with his well-known Roman Catholic controversy with Charles Butler (1750-1832). He was an energetic supporter of the Tory party, even when it acted contrary to his views in passing the Roman Catholic Emancipation Act of 1829. He died on the 18th of September 1869.

"Henry of Exeter," as he was commonly called, was one of the most striking figures in the English Church of the 19th century. His intellect was by no means rather than broad, his position being that of the traditional High Churchman, with little sympathy either with the Evangelicals or with the Tractarians. On the one hand the famous Gorham judgment was the outcome of his refusal to institute to the livings of Brampford Speke a clergyman George Cornelius Gorham (1787-1857), who had openly disavowed his belief in baptismal regeneration; on the other he denounced the equally famous Tract XC in his episcopal charge of 1843. As bishop he was a strict disciplinarian, and...
did much to restore order in a diocese of which the clergy had become extraordinarily demoralized. Though accused of avarice and pluralism, Phillott's was generous in his gifts to the church, founding the theological college at Exeter and spending large sums on the restoration of the cathedral.

PHILO, Jewish Hellenist, and author of an epic poem in Greek hexameters on the history of Jerusalem. Alexander Polyhistor (c. 105–35 B.C.) quotes several passages of the poem, and is the source of the extracts in Eusebius (Preparatio evangelica, ix. 20, 24, 37). This is probably the Philo who is mentioned by Clemens Alexandrinus (Strom. i. 21, 141) and by Josephus (Contra Apionem, i. 23), who calls him "the elder." See M. Phillippson's work on the Jewish poets Ezechiel and Philo (Berlin, 1830).

PHILO, often called Philo Judaeus, Jewish philosopher, appears to have spent his whole life at Alexandria, where he was probably born c. 20–10 B.C. His father Alexander was alabarch or arabarch (that is, probably, chief farmer of taxes on the Arabic side of the Nile), from which he may be concluded that the family was influential and wealthy (Jos. Ant. xviii., 8, 1). Jerome's statement (De vir. ill. 11) that he was of priestly race is confirmed by no other authority. The only event of his life which can be actually dated belongs to A.D. 40, when Philo, then a man of advanced years, went from Alexandria to Rome, at the head of a Jewish embassy, to persuade the emperor Gaius to abstain from claiming divine honour of the Jews. Of this embassy Philo has left a full and vivid account (De legatione ad Gaium). Various fathers and theologians of the Church state that in the time of Claudius he met St Peter in Rome; but this legend has no historic value, and probably arose because the book De vita contemplativa, ascribed to Philo, in which Eusebius already recognized a glorification of Christian monasticism, seemed to indicate a disposition towards Christianity.

Though we know so little of Philo's own life, his numerous extant writings give the fullest information as to his views of the universe, its life, and his religious and scientific aims, and so enable us adequately to estimate his position and importance in the history of thought. He is quite the most important representative of Hellenistic Judaism, and his writings give us the clearest view of what this development of Judaism was and aimed at. The development of Judaism in the diaspora (q.v.) differed in important points from that in Palestine; where, since the successful opposition of the Maccabees to the Hellenization which Antiochus Epiphanes had sought to carry through by force, the attitude of the nation to Greek culture had been essentially negative. In the diaspora, on the other hand, the Jews had been deeply influenced by the Greeks; they soon more or less forgot their Semitic mother-tongue, and with the language of Hellen they appropriated much of Hellenic culture. They were deeply impressed by that irresistible force which was blending all races and nations into one great cosmopolitan unity, and so Jews too too often dispersion became in speech and nationality Greeks, or rather "Hellenists." Now the distinguishing character of Hellenism is not the absolute disappearance of the Oriental civilizations before that of Greece but the combination of the two with a preponderance of the Greek element. So it was with the Jews, but in their case the old religion had much more persistence than in other Hellenistic circles, though in other respects they too yielded to the superior force of Greek civilization. This we must hold to have been the case not only in Alexandria but throughout the diaspora from the commencement of the Hellenistic period down to the later Roman Empire. It was only after ancient civilization gave way before the barbarian immigrations and the rising force of Christianity that rabbinism became supreme even among the Jews of the diaspora. This Hellenistic-Judaic phase of culture is sometimes called "Alexandrian," and the expression is justifiable if it only means that in Alexandria it attained its highest development and flourished most. For here the Jews began to busy themselves with Greek literature even under their own rulers, the first Ptolemies, and here the law and other Scriptures were first translated into Greek; here the process of fusion began earliest and proceeded with greatest rapidity; here, therefore, also the Jews first engaged in a scientific study of Greek philosophy and transplanted that philosophy to the soil of Judaism. We read of a Jewish philosopher Aristobulus in the time of Ptolemy VI. Philometor, in the middle of the 2nd century B.C., of whose philosophical commentary on the Pentateuch fragments have been preserved by Clement of Alexandria and Eusebius. So far as we can judge from these, his aim was to put upon the sacred text a sense which should appeal even to Greek readers, and in particular to get rid of all anthropomorphic utterances about God. Eusebius regards him as a Peripatetic. We may suppose that this philosophical line of thought had its representatives in Alexandria between the times of Aristobulus and Philo, but we are not acquainted with the names of any such. Philo certainly, to judge by his historical influence, was the greatest of all these Jewish philosophers, and in his case we can follow in detail the methods by which Greek culture was harmonized with Jewish faith. On one side he is quite a Greek, on the other quite a Jew. His language is formed on the best classical models, especially Plato. He knows and often cites the great Greek poets, particularly Homer and the tragedians, but his chief studies had been in Greek philosophy, and he speaks of Heraclitus, Plato, the Stoics and the Pythagoreans in terms of the highest veneration. He had appropriated their doctrines so completely that he must himself be reckoned among the Greek philosophers; his system was eclectic, but the borrowed elements are combined into a new unity with so much originality that at the same time he may fairly be regarded as presenting a philosophy of his own, which has for its characteristic feature the constant prominance of a fundamental religious idea. Philo's closest affinities are with Plato, the later Pythagoreans and the Stoics. Yet with all this Philo remained a Jew, and a great part of his writings is expressly directed to recommend Judaism to the respect and, if possible, the acceptance of the Greeks. He was not a stranger to the specifically Jewish culture that prevailed in Palestine; in Hebrew he was not proficient, but the numerous etymologies he gives show that he had made some study of that language. His method of exegesis is in point of form identical with that of the Palestinian scribes, and in point of matter coincidences are not absolutely rare. But above all his whole works prove on every page that he felt himself to be thoroughly a Jew, and desired to be nothing else. Jewish "philosophy" is to him the true and highest wisdom; the knowledge of God and of things divine and human which is contained in the Mosaic Scriptures is to him the deepest and the purest.

If now we ask wherein Philo's Judaism consisted we must answer that it lies mainly in the formal claim that the Jewish people, in virtue of the divine revelation given to Moses, possesses the true knowledge of things divine and human. The chief point which is his recognition that the Mosaic Scriptures of the Pentateuch are of absolute divine authority, and that everything they contain is valuable and significant because divinely revealed. The other Jewish Scriptures are also recognized as prophetic, i.e. as the writings of inspired men, but he does not place them on the same lines with the law, and he quotes them so seldom that we cannot determine the compass of his canon. The

1 Euseb., H. E. ii. 17, 1; Jer. ut supra; Phot. Bib. Cod. 105; Subi, i. 9. "Φιλός."

2 See the list of these in Vallarsi's edition of Jerome (ii. 731–734), and compare Siegfried, "Philosophische Studien, in Merz's Archiv. ii. 143–163 (1872).

3 See Siegfried, Philo, pp. 142–159.
decisive and normative authority is to him the "holy laws" of Moses, and this not only in the sense that everything they contain is true but that all truth is contained in them. Everything that is right and good in the doctrines of the Greek philosophers had already been quite as well, or even better, taught by Moses. Thus, since Philo had been deeply influenced by the teachings of Greek philosophy he actually finds in the Pentateuch everything which he had learned from the Greeks. From these premises he assumes as requiring no proof that the Greek philosophers must in some way have drawn from Moses, a view indeed which is already expressed by Aristobulus. To carry out these presuppositions called for an exegetical method which seems very strange to us, that, namely, of the allegorical Interpretation of Scripture. The allegorical method had been practised before Philo's date in the rabbinical schools of Palestine, and he himself expressly refers to its use by his predecessors, but the view does belong to all times. Justification is requisite. With its aid he discovers indications of the profoundest doctrines of philosophy in the simplest stories of the Pentateuch.

This merely formal principle of the absolute authority of Moses is really the one point in which Philo still holds to genuinely Jewish conceptions. In the whole substance of his philosophy the Jewish point of view is more or less completely modified—sometimes almost extinguished—by what he has learned from the Greeks. Comparatively speaking, he is most truly a Jew in his conception of God. The doctrine of monothelism, the stress laid on the absolute majesty and sovereignty of God above the world, the principle that He is to be worshipped without images, are all points in which Philo justly feels his superiority as a Jew over popular heathenism. But only over popular heathenism, for the Greek philosophers had long since arrived at at least a theoretical monothelism, and their influence on Philo is nowhere more strongly seen than in the detailed development of his doctrine of God. The specifically Jewish (i.e., particularistic) conception of the election of Israel, the obligation of the Mosaic law, the future glory of the chosen nation, have almost disappeared; he is really a cosmopolitan and praises the Mosaic law just because he deems it cosmopolitan. The true sage who follows the law of Moses is the citizen not of a particular state but of the world. A certain attachment which Philo still manifests to the particularistic conceptions of his race is meant only "in majorem Judaorum gloriam." The Jewish people has received a certain preference from God, but only because it has the most virtuous ancestry and is itself distinguished for virtue. The Mosaic law is binding, but only because it is the most righteous, humane and rational of laws, and even its outward ceremonies always disclose rational ideas and aims. Lastly, outward prosperity is promised to the pious, even on earth, but this is only a shadow of the future, when all shall be drawn to the true God. Thus, in the whole substance of his view of the universe, Philo occupies the standpoint of Greek philosophy rather than of national Judaism, and his philosophy of the world and of life can be completely set forth without any reference to conceptions specifically Jewish.

His doctrine of God starts from the idea that God is a Being absolutely bare of quality. All quality in finite beings has limitation, and no limitation can be predicated of God, who is eternal, unchangeable, simple substance, free, self-sufficient, better than the good and the beautiful. To predicate any quality (περβαρία) of God would be to reduce Him to the sphere of finite existence. Of Him we can say only that He is, not what He is, and such purely negative predications as to His being appear to Philo, as to the later Pythagoreans and the Neoplatonists, the only way of securing His absolute elevation above the world. At bottom, no doubt, the meaning of these negations is that God is the most perfect being; and so, conversely, we are told that God contains all perfection, that He fills and encompass all things with His being.

A consistent application of Philo's abstract conception of God would exclude the possibility of any active relation of God to the world, and therefore of the Being absolutely without quality and movement cannot be conceived as actually concerned with the multiplicity of individual things. And so in fact Philo does teach that the absolute perfection, purity and loftines of God would be violated by direct contact with imperfect, impure and finite things. But the possibility of a connexion between God and the world is reached through a distinction which forms the most important point in his theology and cosmology; the proper Being of God is distinguished from the infinite multiplicity of divine Ideas or Forces: God himself is without quality, but He disposes of an infinite variety of divine Forces, through whose mediation an active relation of God to the world is brought about. In the details of his teaching as to these mediating entities Philo is guided partly by Plato and partly by the Stoics, but at the same time he makes use of the Confucianism through which he worked his own ideas. Following Plato, he first calls them Ideas or ideal patterns of all things; they are thoughts of God, yet possess a real existence, and were produced before the creation of the sensible world, of which they are the types. But, in distinction from Plato, Philo's Ideas are at the same time efficient causes or Forces (πρόων), which bring unformed matter into order conformably to the patterns within themselves, and are in fact the media of all God's activity in the world. This modification of the Platonic Ideas is due to Stoic influence, which appears also when Philo gives to the ιδεα or πρόωγες the name of λόγος, i.e., operative ideas—parts, as it were, of the operative Ideas. For, when Philo calls his mediating entities λόγος, the sense designed is analogous to that of the Stoics when they call God the Logos, i.e., the Reason which operates in the world. But at the same time Philo maintains that the divine Forces are identical with the "daemons" of the Greeks, and the "angels" of the Jews, i.e., servants and messengers of God by means of which He communicates with the finite world. All this shows how uncertain was Philo's conception of the nature of these mediating Forces. On the one hand they are nothing else than Ideas of individual things conceived in the mind of God, and as such ought to have no other reality than that of immanent existence in God, and so Philo says expressly that the totality of Ideas, the θεοτόκος τοπόσος, is simply the Reason of God as Creator (θεο τοπόσος ήλ θεοτόκος). Yet, on the other hand, they are represented as hypostases distinct from God, individual entities existing independently and apart from Him. This vacillation, however, as Zeller and other recent writers have justly remarked, is necessarily involved in Philo's premises, for, on the one hand, it is God who works in the world through His Ideas, and therefore they must be identical with God; but, on the other hand, God is not to come into direct contact with the world, and therefore the Ideas must be mediators between God and the world. The same inevitable amphiboly dominates in what is taught as to the supreme Idea or Logos. Philo regards all individual Ideas as comprehended in one highest and most general Idea or Force—the unity of the individual Ideas—which he calls the Logos or Reason of God, and which is again regarded as operative Reason. The Logos, therefore, is the highest mediator between God and the world, the firstborn son of God, the archangel who is the vehicle of all revelation, and the high priest who stands before God on behalf of the world. Through him the world was created, and so he is identified with the creative Word of God in Genesis (the Greek λόγος meaning both "reason" and "word"). Here again, we see, the philosopher is unable to escape from the difficulty that the Logos is at once the immanent Reason of God, and yet also a hypostasis standing between God and the world. The whole doctrine of this mediatorial hypostasis is a strange interweaving of very dissimilar threads; on one side the way was prepared for it by the older Jewish distinction between the Wisdom of God and God Himself, of which we find the beginnings even in the Old Testament (Job xxxvii. 12 seq.; Prov. viii., ix.), and the fuller development in the books of Ecclesiasticus and Wisdom, the latter of which comes very near to Philo's ideas if we substitute for the term "wisdom"...
that (of divine) "reason." In Greek philosophy, again, Philo, as we have seen, chiefly follows the Platonic doctrines of Ideas and the Soul of the World, and the Stoic doctrine of God as the k~e-wnx{swv, a principle operative in the world. In its Stoic form the latter doctrine was pantheistic, but Philo could adapt it to his purpose simply by drawing a sharper distinction between the Logos and the world.

Like his doctrine of God, Philo's doctrine of the world and creation rests on the presupposition of an absolute metaphysical contrast between God and the world. The world can be ascribed to God only in so far as it is a cosmos or orderly world; its material substratum is not even indirectly referable to God. Matter (v{y, or, as the Stoics said, oikou) is a second principle, but in itself an empty one, its essence being a mere negation of all true being. It is a lifeless, unmoved, shapeless mass, out of which God formed the actual world by means of the Logos and divine Forces. Strictly speaking, the world is only formed, not created, since matter did not originate with God.

Philo's doctrine of man is also strictly dualistic, and is mainly derived from Plato. Man is a twofold being, with a higher and a lower phase. The pure souls which fill airy space, those nearest the earth are the rational souls and descend into sensible bodies; these souls are the Godward side of man, but on his other side man is a creature of sense, and so has in him a fountain of sin and all evil. The body, therefore, is a prison, or a grave for the soul which seeks to rise again to God. From this anthropological point of view, the principles of Philo's ethics are derived, his highest maxim necessarily being deliverance from the world of sense and the mortification of all the impurities of sense. In carrying out this thought, as in many other details of his ethical teaching, Philo closely follows the Stoics. But he is separated from Stoical ethics by his strong religious interests, which carry him to very different views of the means and aim of ethical development. The Stoics cast man upon his own resources; Philo points him to the assistance of God, without whom a captive to sense, could never raise himself to walk in the ways of true wisdom and virtue. And as moral effort can bear fruit only with God's help, the ultimate goal of God is the plan of that effort. Even in this life the truly wise and virtuous is lifted above his sensible existence, and enjoys in ecstasy the vision of God, his own consciousness sinking and disappearing in the divine light. Beyond this ecstasy lies but one further step, viz. entire liberation from the body and sense and the return of the soul to its original condition; it came from God and must rise to Him again. But natural death brings this consummation only to those who, while they lived on earth, kept themselves free from attachment to the things of sense; all others must at death pass into another body; transmigration of souls is in fact the necessary consequence of Philo's premises, though he seldom speaks of it expressly.

Philo's literary labours have a twofold object, being directed either to expound the true sense of the Mosaic law, i.e. the philosophy which we have just described, to his Jewish brethren, or to convince heathen readers of the excellence, the supreme purity and truth, of the Mosaic law, whose holy records contain the deepest and most perfect philosophy, the best and most divine revelation which has been made to man. Thus as a literary figure Philo, in conformity with his education and views of life, stands between the Greeks and the Jews, seeking to gain the one by the other, and the Greeks for Judaism, yet always taking it for granted that his readers never really are Jewish, and just on that account truly philosophical and cosmopolitan. The titles of the numerous extant writings of Philo present at first sight a most confusing multiplicity. More than three-fourths of them, however, are really mere sections of a small number of larger works. Three such great works on the Pentateuch can be distinguished.

Of the Greek we have numerous but short fragments in various Florilegia. The interpretations in this work are partly literal and partly allegorical.

11. Philo's most important work is the Æmeros Òpou evgenh, (Euseb. H. E. ii. 18, 1; Phot. Bibl. Cod. 103), a vast and copious allegorical commentary on Genesis, dealing with chaps. ii.-iv., and the universe, and with selected passages in the later chapters. The readers in view are mainly Jews, for the work is modelled on the rabbinic Midrash. The main idea is that the characters which appear in Genesis are properly allegories of states of the soul (Ôpou evgenh). All persons and actions being interpreted in this sense, the work as a whole is an allegorical interpretation of the universe and ethics. It begins with Gen. i. 1, for the De mundi opificio, which treats of the creation according to Gen. i., does not belong to these series of allegorical commentaries, but deals with the actual history of creation, and that under a quite different literary form. With this exception, however, the Æmeros Òpou evgenh includes all the treatises in the first volume of Mangy's edition, viz.

that of Genesis and Exodus, but with lacunae. A Latin translation of about half of the fourth books on Genesis (Phil. Jud. CII. quaeant. . . . super Gen.) has been preserved. Of the Greek we have numerous but short fragments in various Florilegia. The interpretations in this work are partly literal and partly allegorical.

legislation was conform to the will of nature, and that therefore those who followed it were true cosmopolitans; (b) the Biographies of the Virtuous.—so, to speak, the living unwritten laws which, unlike written laws, present the general types of moral conduct; (c) the Commentaries, or, to speak more correctly, the Notes and chapters of the law, (d) the special laws belonging to each of these ten. An appendix adds a view of such laws as do not fall under the rubrics of the decalogue, arranged under the headings of certain cardinal virtues.

The treatises which belong to this work are the following: (1) Περὶ τὴν Μάριας κοσμοσύνης (De mundi orificio, M. i. 1-42). This work does not fall within the number of the allegorical commentaries. On the contrary it is an absolute beginning of the most important legislation of Philo, and makes clear its immediate connection with the De mundi orificio. The position of the De mundi orificio at the head of the allegorical commentaries, which is at present usual in the editions, seems indeed to go back to the very early date, for even Euzebius claims his work from the De orificio mundi. The first treatise (Præpf. Ep. viii. 12 fin., ed. Gaisford). The group of the Μαριανά ένδειξε (De Abrah. M. ii. 1-40). Abraham is expressly named in the title of this treatise by (2) Μαρίας ένδειξε (De Josepho, M. ii. 41-79), where Joseph is taken as the type of the pattern of the wise man in his civil relations. The Biographies of the Hellenistic Kings (De præm. sacrificiorum, M. ii. 180-209) and (3) Περὶ τῶν ἀνδρών ἐν ἑλήσθαν τοῖς ἀνθρώποις τοῦ ἁγίου πάσας (De sacrificiis, ii. 232-237), is, in the fourth (Præpf. Ep. VIII. 151), where the king of the Philo's reckoning there is a survey of all the laws about feasts; under the sixth (adultery) an account of matrimonial law; and so on. According to Eusebius the work embraced four books, which seem to have been divided into five sections: (i) the twelve commandments, (ii) the third, fourth and fifth commandments, (iii) the seventh, eighth and ninth commandments, (iv) the tenth commandments (De sacrificiis, ii. 353-374), that is to say, not merely the tracts De judicis (ii. 344-348) and De concipisciente (ii. 348-358), but also those De justitia (ii. 359-361) and De creatione principum (ii. 361-374). The last section is, besides the special laws connected with the law, the Mosaic code, and the nature of the code. (5) The second treatise treats of the various parts of the code which, however, certainly belongs to the fourth book, of which the superscription expressly bears that it treats also of the De analogy. With this begins the appendix to the work De specialibus legibus, forming the second (Præpf. Ep. viii. 151), which is, however, a separate and independent work. Such Mosaic laws are brought together as could not be dealt with under any of the decalogue rubrics. The continuation of this appendix forms a book by itself. (6) Περὶ παραγωγῆς τῶν προφητών καὶ ἐκδηλώσεως τῆς προφητείας (De praem. sacc. ii. 249-257), two parts which constitute a single whole and deal with the promises and threatenings of the laws.

IV. Besides the above-named three great works for the Pentateuch, are three others which follow the same general lines, which the following have reached us either in their entirety or in fragments. (1) Περὶ τὴν Μάριας κοσμοσύνης (Vita Mosis, lib. i.-iii., M. ii. 80-179). It is usual to group this, as being biographical in its character. But it is really a treatise. It is written immediately after the De Josepho with the large work on the Mosaic legislation. But, as has been seen, the Blaie οἱσοφοὶ are intended to represent the general types of morality, while Moses is by no means so dealt with, but as a unique individual. All that can be said is that the literary character of the Vita Mosis is that it is that of the larger work. As in the latter the Mosaic legislation, so in the former the activity of the legislator himself, is delineated for the benefit of Gentile readers. (2) Περὶ τῶν πάντων σπονδών καὶ ἐκδηλώσεως. (Quod omnis probus liber sit, M. ii. 445-470). In the introduction to this treatise reference is made to an earlier book which had for its theme the converse proposition. The entire work was abridged and published under the title De deo, spondeis, and the fourth book of the Laws of the alien (De legatione ad Gaismo, M. ii. 545-600). The genuineness of the writing now possessed by us is not undisputed; but see Lucius, Der Esaisenmum (1661), pp. 13-23, (3) Περὶ τῶν κράτων τῶν Πλούτων (De legatione ad Gaismo, M. ii. 125-187). This treatise is a Latin version of the De legatione ad Gaismo, and it is the case that divine honors should be everywhere accorded to him, and how the Jews of Alexandria in vain sought relief by a mission to Rome which was headed by Philo. But both together were only parts of a larger work, in five books, of which the whole has been edited by Calig. The two Greek fragments relate to the introduction to the Adversus Flaccum that it had been preceded by another book in which the Jewish persecutions by Sejanus, under the reign of Tiberius, were spoken of, and the Chronicon of Eusebius (ed. Schoene, ii. 1, 123 ff.) is a full account of the work. There is no reason to think that it was related in the second book of the work now under discussion. But from the conclusion of the Legatio ad Gaismo, which we still possess, we learn that it was also followed by another book which exhibited the same antagonism of Jewish and Gentile law. This work we make out five books in—all the number actually given by Eusebius (H.E. ii. 57, 1). (5) Περὶ προφητικά (De providentia). This work has reached us only in an Armenian translation, which has been published with a French commentary by M. Vandel (H.E. ii. 57, 1). It may be that it is mentioned by its Greek title in Eusebius (H.E. ii. 18, 6; Præpf. Ep. vii. 20 fin., viii. 13 fin., ed. Gaisford). The Armenian text gives two books, but of these the first, if genuine at all, is only an abridgment of the first two, and the second (H. E. ii. 18, 6) is a work by a different author. Two small Greek fragments occur in the Ephes. Schi. Lev. et coll. (ii. 1, pp. 99, 100a). (7) Εορμένος, a writing now known to us only through fragments preserved in Eusebius, Præpf. Ep. viii. 6, 7. The title, as Bernays shows, means "Counsels, " "Recommendations, " the reference being to such laws of the Jews as can be recommended also to non-Jewish readers. (8) Περὶ προπαλαμάδων, a treatise written in P. Eusebii, ii. 18, 6, which was printed with a French commentary. It is a work in which the emphasis is given in Eusebius, Præpf. Ep. vii. 11. To this place also, perhaps, belongs the De nobilitate (M. ii. 437-444), which treats of that true noblesse of wisdom which in the Jewish people also is not wanting. V. The most important treatises are the following: (1) Περὶ τῶν ἀνδρῶν τῶν ἁγίων (De vita contemplativa). This contains the sole original account of an ascetic community known as the Therapeutæ (q.v.) having their home on the shores of Lake Mareotis. These were held by Eusebius, and to many other Christian writers as the earliest Christian monasteries, which of course could not be the case if it was a genuine work of Philo. On this account, amongst others, it was held to be spurious by Graetz and F. L. Lucius; and this view prevails to this day. But, however, L. Massie has shown with great thoroughness that in language and thought alike it is essentially Philonic, and the genuineness of the book has been also affirmed by P. Wendland, and it is generally held by many who refer to it. It has been called (De incorruptibilitate mundi), declared unauthentic by Z. Frankel and J. Bernays, and has been successfully defended by F. Cumont. (2) Περὶ τῶν ἀνδρῶν τῶν ἁγίων (De mundo). It is generally agreed that, in L. C. Massebieau's opinion, it is "nothing but a compilation from various portions of the προφητείας κελέων and other Philonic works." (3) Two discourses, De Sempore and De Iona, extant only in Armenian, and certain other writings of the same kind. These appear clearly to have been a part of a unique series of works, which cannot claim to be his work. (4) Περὶ τῶν πάντων σπονδών καὶ ἐκδηλώσεως. (Quod omnis probus liber sit) has been questioned by Z. Frankel and R. Ansfeld; but their arguments would rather point to its being a work of a later period, either by someone else or by Philo. (6) Περὶ προφητικά (De providentia). See the whole of this work.
only in an Armenian version, consists of two books, the first of which appears to be in a Christian recension, but there is no reason for denying its Phoenician origin.

Editions.—Till recent days the best edition was that of Mangay (2 vols., London, 1854). Later editions have been due to Mangay (Leipzig, 1851). Both are still very useful, but for scholars they will be superseded by the enlarged and critical edition of Leopold Cohn and Paul Edlund (Berlin, 1896-1902). See also papers by Cohn in Hermes, 1892, vol. iv., and 1893, vol. v. There is also an English translation of the old text by C. D. Yonge (4 vols., London, 1854).

PHILODEMUS, of Athens, Greek historian during the 3rd century B.C., was a member of a priestly family. He was a seer and interpreter of signs, a man of considerable influence. He was strongly anti-Macedonian in politics, and a bitter opponent of Demetrius Poliorcetes. When Antigonus Gonatas, the son of the latter, besieged and captured Athens (261), Philodemus was put to death for having supported Ptolemy Philadelphus, who had encouraged the Athenians in their resistance to Macedonia. His investigations into the usages and customs of his native Attica were embodied in an Allithis, in seventeen books, a history of Athens from the earliest times to 262 B.C. Considerable fragments are preserved in the lexicographers, scholiasts, Athenaeus, and elsewhere. The work was epitomized by the author himself, and later by Asinus Pollio of Tralles (perhaps a freedman of the famous Gaius Asinius Pollio). Philodemus also wrote on oracles, divination and sacrifices; the mythology and religious observances of the Jews; Old Testament, the myths of Sophocles; the lives of Euripides and Pythagoras; the foundation of Salamis. He composed a number of Latin epigrams, which were published in the edition of Orelli (1826) and Cohn (1880); and made a collection of Attic inscriptions, the first such collection in Greece.

Editions of the fragments by J. C. Orelli (1826) and C. Müller, Frag. hist. græcorum, vol. i. (1855). W. Wagenfeld brought out what he claimed to be a complete translation of Philotheon's works, which is known in a convent in Portugal, now considered spurious. There are English translations by I. P. Cory (1828) and Bishop R. Cumberland (1798).

settled in Rome in the time of Cicero. He was a friend of Calpurnius Piso, and was implicated in his proselygy by Cicero (in *Pisone*, 20), who, however, praises him warmly for his philosophic views and for the *elegans lascivia* of his poems (cf. Horace, *Satires*, 1. 2. 120). The Greek anthology contains thirty-four of his epigrams. From the excavations of the villa at Herculanenum (q.v.) there have been recovered thirty-six treatises attributed to Philodemus, and it has been suggested that the villa was actually owned by him; but this is generally denied. These works deal with music, rhetoric, ethics, signs, virtues and vices, and defend the Epicurean standpoint against the Stoics and the Peripatetics.

The *Rhetorique* has been edited by Sudhau (1892—1895); the *De Ina* and the *De Falsis* by Kranepol (1884—1886). The *De Vite et Usus* (1868); *De Mort* by Meelker (1886). See *Hercul. Volum.* (Oxford, 1824 and 1861); Mayor on Cicero’s *De Nat. Doctr.* (1871).

**PHILOLAUS** (b. c. 480), Greek philosopher of the Pythagorean school, was born at Tarentum or at Crotona 1 (so Diog. Laërt. viii. 84). He was said to have been intimate with Democritus, and was probably one of his teachers. After the death of Pythagoras great dissensions prevailed in the cities of lower Italy. According to some accounts, Philolaus, obliged to flee, took refuge first in Lucania and then at Thebes, where he lived till the time of Alexander. Philolaus, who subsequently was still young men (seviexwos), were present at the death of Socrates. Before this Philolaus had returned to Italy, where he was the teacher of Archytas. He entered deeply into the distinctively Pythagorean number theory, particularly dwelling on the properties inherent in the decimal—the sum of the first four numbers, consequently the fourth triangular number, the *tetractys* (see Vit. *Pythag.* ap. *Phat. Bibli.* p. 712)—which he called great, all-powerful, and all-producing. The great Pythagorean oath was taken by the sacred *tetractys*. The discovery of the regular solids is attributed to Pythagoras by Eudemus, and Empedocles is stated to have been the first who maintained that there are four elements. Philolaus, connecting these ideas, held that the elementary nature of bodies depends on their form, and assigned the tetrahedron to fire, the octahedron to air, the icosahedron to water, and the cube to earth; the dodecahedron he assigned to a fifth element, ether, or, as some think, to the universe (see Plut. *De Ph. ii. 6, κα του δεκακάνδρον των των παντων σφαιρων* et *Stob. *Ecl. Phys. i. 10, δ των σφαιρων ολης). This theory, however superficial from the standpoint of observation, indicates considerable knowledge of geometry and gave a great impulse to the study of the science. Following Parmenides, Philolaus regarded the soul as a “mixture and harmony” of the bodily parts; he also assumed a substantial soul, whose existence in the body is an exile on account of sin.

Philolaus was the first to propound the doctrine of the motion of the earth; some attribute this doctrine to Pythogoras, but there is no evidence in support of their view. Philolaus supposed that the sphere of the fixed stars, the five planets, the sun, moon and earth, all moved round the central fire, which he called the hearth of the universe, the house of Zeus, and the mother of the gods (see *Stob. Ecl. Phys. i. 485*); but as there were only seven revolving bodies he conceived, in accordance with his number theory, a tenth, which he called counter-earth, *arξικανων*. He supposed the sun to be a disk of glass which reflects the light of the universe. He made the lunar month consist of 29[1/2] days, the lunar year of 354, and the solar year of 365[1/3] days. He was the first who published a book on the Pythagorean doctrines, a treatise of which Plato made use in the composition of his *Timaeus*. This work of the Pythagorean, to which the mystical name *Báxox* is sometimes given, seems to have consisted of three books: (1) *Περὶ κόσμου*, containing a general account of the origin and arrangement of the universe; (2) *Περὶ φύσεως*, an exposition of the nature of numbers; (3) *Περὶ ψυχῆς*, on the nature of the soul.

---

1 Böckh places his life between the 70th and 95th Olympiads (496—396 B.C.). He was a contemporary of Socrates and Democritus, but senior to them, and was probably somewhat junior to Empedocles, so that his birth may be placed at about 480.

**PHILOLOGY**, the generally accepted comprehensive name for the study of the word (Gr. *λαξιας*, or languages; it designates that branch of knowledge which deals with human speech, and with all that speech discloses as to the nature and history of man. Philology has two principal divisions, corresponding to the two uses of “word” or “speech,” as signifying either what is said or the language in which it is said, as either the thought expressed—which, when recorded, takes the form of literature—or the instrumentality of its expression: these divisions are the literary and the linguistic. Not all study of literature, indeed, is philological: as when, for example, the records of the ancient Chinese are ransacked for notices of astronomical or meteorological phenomena, or the principles of geometry are learned from the textbook of a Greek sage; while, on the other hand, to study Ptolemy and Euclid for the history of the sciences represented by them is philological more than philological, perhaps. Philology is divided into two literary parts: (1) the literary side: as when the vocabulary of a community (say of ancient Indo-Europeans or Aryans) is taken as a document from which to infer the range and grade of knowledge of its speakers, their circumstances and their institutions. The two divisions thus do not admit of absolute distinction and separation, though for some time past tending toward greater independence. The literary is the older of the two; it even occupied until recently the whole field, since the scientific study of language itself has arisen only within the 19th century. Till then, literary philology included linguistic, as a merely subordinate and auxiliary part, the knowledge of a language being the necessary key to a knowledge of the literature written in that language. When, therefore, instead of studying each language by itself for the sake of its own literature men began to compare one language with another, in order to bring to light their relationships, their structures, their histories, the name “comparative philology” naturally enough suggested itself and came into use as the new method; and this name, awkward and trivial though it may be, has become so firmly fixed in English usage that it can be only slowly, if at all, displaced. European usage (especially German) tends more strongly than English to restrict the name philology to its older office, and to employ for the recent branch of knowledge a specific term, like those that have gained more or less currency with us also; as glottic, glossology, linguistics, linguistic science, science of language, and the like. It is not a question of absolute propriety or correctness, since the word philology is in its nature wide enough to imply all language-study of whatever kind; it is one, rather, of the convenient distinction of methods that have grown too independent and important to be any longer well included under a common name.

I.—The Science of Language in general.

Philology, in all its departments, began and grew up as classical; the history of our civilization made the study of Greek and Latin long the exclusive, still longer the predominant and regulating, occupation of secular scholarship. The Hebrew and its literature were held apart, as something of a different order, as sacred. It was not imagined that any tongue to which culture and literature did not lend importance was worthy of serious attention from scholars. The first essays in comparison, likewise, were made upon the classical tongues, and were as erroneous in method and fertile in false conclusions as was to be expected, considering the narrowness of view and the controlling prejudices of those who made them; and the admission of Hebrew to the comparison only added to the confusion. The change which the past century has seen has been a part of the general scientific movement of the age, which has brought about the establishment
of so many new branches of knowledge, both historical and physical, by the abandonment of shackling prejudices, the freedom of inquiry, the recognition of the dignity of all knowledge, the wide-reaching assemblage of facts and their objective comparison, and the resulting constant improvement of method. Literary philology has had its full share of advantage from this movement; but linguistic philology has been actually created by it out of the crude observations and wild deductions of earlier times, as truly as chemistry out of alchemy, or geology out of diluvianism. It is unnecessary here to follow out the details of the development; but we may well refer to the decisive influence of one discovery, the decisive action of one scholar. It was the discovery of the special relationship of the Aryan or Indic-European languages, depending in great measure upon the introduction of the Sanskrit as a term in their comparison, and demonstrated and worked out by the German scholar Bopp, that founded the science of linguistic philology. While there is abundant room for further improvement, it yet appears that the grand features of philological study, in all its departments, are now so distinctly drawn that no revolution of its methods, but only their modification in minor respects, is henceforth probable. How and for what purposes to investigate the literature of any people (philology in the more proper sense), combining the knowledge thus obtained with that derived from other sources; how to study and set forth the material and structure and combinations of a language (grammar), or of a body of related languages (comparative grammar); how to co-ordinate and interpret the general phenomena of language, as variously illustrated in the infinitely varying facts of different tongues, so as to exhibit its nature as a factor in human history and its methods of life and growth (linguistic science)—these are what philology teaches.

The study of language is a division of the general science of anthropology (q.v.), and is akin to all the rest in respect to its objects and its methods. Man as we now see him is a twofold being: in part the child of nature, as to his capacities and desires, his endowments of mind and body; in part the creature of education, by training in the knowledge, the arts, the social conduct, of which his predecessors have gained possession. And the problem of anthropology is this: how natural man has become cultivated man; how a being thus endowed by nature should have begun and carried on the processes of acquisition which have brought him to his present state. The results of his predecessors' labours are not transmutated for his benefit into natural instincts, in language or in anything else. The child of the most civilized race, if isolated and left wholly to his own resources, aided by neither the example nor the instruction of this fellow who would no more speak the speech of his ancestors than he would build their houses, fashion their clothes, practise any of their arts, inherit their knowledge or wealth. In fact, he would possess no language, no arts, no wealth, but would have to go to work to acquire them, by the same processes which began to win them for the first human beings. One advantage he would doubtless enjoy: the descendant of a cultivated race has an enhanced aptitude for the reception of cultivation; he is more cultivable; and this is an element that has to be allowed for in comparing present conditions with past, as influencing the rate of progress, but nothing more. In all other respects it is man with the endowments which we now find him possessed of, but destitute of the gradually accumulated results of the exercise of his faculties, whose progress we have to explain. And it is, as a matter of necessity, by studying recent observable modes of acquisition, and transferring them, with due allowance for different circumstances, to the more primitive periods, that the question of first acquisition or origin is to be solved, for language as for tools, for arts, for family and social organization, and the rest. There is just as much and just as little reason for assuming miraculous interference and aid in one of these departments as in another. If men have been left to themselves to make and improve instruments, to form and perfect modes of social organization, by implanted powers directed by natural desires, and under the pressure of circumstances, then also to make and change the signs that constitute their speech. All expressions, as all instruments, are at present, and have been, through the known past, made and changed by the men who use them; the same will have been the case in the unknown or prehistoric past. And we command now enough of the history of language, with the processes of its life and growth, to determine with confidence its mode of origin—within certain limits, as will appear below.

It is beyond all question, in the first place, that the desire of communication was the only force directly impelling men to the production of language. Man's sociality, his disposition to band together with his fellows, cause of language-making, is one of his most fundamental characteristics. To understand those about one and to be understood by them is now, and have been from the very beginning, a prime necessity of human existence; we cannot conceive of man, even in his most undeveloped state, as without the recognition of it. Communication is still the universally recognized office of speech, and to the immense majority of speakers the only one; the common man knows no other, and can only with difficulty and imperfectly be brought to see that there is any other; of the added distinctness and reach of mental action which the possession of such an instrumentality gives him he is wholly unconscious; and it is obvious that what the comparatively cultivated being of to-day can hardly be made to realize can never have acted upon the first men as a motive to action. It may perhaps be made a question which of the two uses of speech, communication or the facilitation of thought is the higher; there can be no question, at any rate, that theformer is the broader and the more fundamental. That the kind and degree of thinking which we do nowadays would be impossible without language—signs is true enough; but so also it would be impossible without written signs. That there was a time when men had to do what mental work they could without the help of writing, as an art not yet devised, we have no difficulty in realizing, because the art is of comparatively recent device, and there are still communities enough that are working without it; it is much harder to realize that there was a time when speaking also was an art not yet attained, and that men had to carry on their rude and rudimentary thinking without it. Writing too was devised for conscious purposes of communication only; its esoteric uses, like those of speech, were at first unsuspected, and incapable of acting as an inducement; they were not noticed until made experience of, and then only by those who look beneath the surface of things. There is no analogy closer and more instructive than this between speech and writing. But analogies are abundant elsewhere in the history of human development. Everywhere it is the lower and more obvious inducements that are first effective, and that lead gradually to the possession of what serves and stimulates higher wants. All the arts and industries have grown out of men's effort to get enough to eat and protection against cold and heat—just as language, with all its uses, out of man's effort to communicate with their fellows. As a solitary man now would never form even the beginnings of speech, as one separated from society unlearns his speech by disuse and becomes virtually dumb, so early man, with all his powers, would never have acquired speech, save as to those powers was added sociality with the needs it brought. We might conceive of a solitary man as housing and dressing himself, devising rude tools, and thus lifting himself a step from wildness toward cultivation; but we cannot conceive of him as ever learning to talk. Recognition of the impulse to communication as the efficient cause of language-making is an element of primary importance in the theory of the origin of language. No one who either leaves it out of account or denies it will, however ingenious and entertaining his speculations, cast any real light on the earliest history of speech. To inquire under what peculiar circumstances, in connexion with what mode of individual or combined action, a first outburst of oral expression may have taken place, is, on
the other hand, quite futile. The needed circumstances were always present when human beings were in one another's society; there was an incessant drawing-on to attempts at mutual understanding which met with occasional, and then ever more frequent and complete success. There inheres in most reasoning upon this subject the rooted assumption, governing opinion even when not openly upheld or consciously made, that conceptions have real natural names, and that in a state of nature these will somehow break forth and reveal themselves under favouring circumstances. The falsity of such a view is shown by our whole further discussion.

The character of the motive force to speech determined the character of the beginnings of speech. That was first signified which was most capable of intelligible signification, not that which was first in order of importance, as judged by any standard which we can apply to it, or first in order of conceptual development. All attempts to determine the first spoken signs by asking what should have most impressed the mind of primitive man are and must be failures. It was the exigencies and possibilities of practical life, in conditions quite out of reach of our distinct conception, that prescribed the earliest signs of communication. So, by a true and instructive analogy, the beginnings of writing are rude depictions of visible objects; it is now thoroughly recognized that no alphabet, of whatever present character, can have originated in any other way; everything else is gradually arrived at from that—as, indeed, in the ingeniously shaping hands of man, from any central body of signs, though but of small extent, all else is attainable by processes of analogy and adaptation and transfer. Now what is that which is directly signifable in the world about us? Evidently the separate acts and qualities of sensible objects, and nothing else. In writing, or signification to the eye, the first element is the rude depiction of the outline of an object, or of that one of the sum of its characteristic qualities which the eye takes note of and the hand is capable of intelligibly reproducing; from that the mind understands the whole complex object itself, and then whatever further may in the circumstances of its use be suggested by it. So, for example, the picture of a tree signifies primarily a tree, then perhaps wood, something made of wood, and so on; that of a pair of outstretched wings signifies secondarily flight, then soaring, height, and whatever else these may lead to. No concrete thing is signifable in its totality or otherwise than by a facile analysis of its constituent qualities and a selection of the one which is both sufficiently characteristic in itself and capable of being called up by a sign before the mind addressed.

And what quality shall be selected depends in great measure upon the instrumentality used for its signification. Of such instrumentality men possess a considerable variety. We must leave out of account that of depiction, as just instanced, because its employment belongs to a much more advanced state of cultivation, and leads the way to the invention not of speech but of the analogous and auxiliary art of writing. There remain gesture, or changes of expression in the face and the body; such as the most mobile parts, the arms and hands; grimace, or the changes of expression of the features of the countenance (in strictness, a variety of the preceding); and utterance, or the production of audible sound. It cannot be doubted that, in the first stages of communicative expression, all these three were used together, each for the particular purposes which it was best calculated to serve. The nearest approach to such action that is now possible is when two persons, wholly ignorant of one another's speech, meet and need to communicate—an imperfect correspondence, because each is trained to habits of expression and works consciously, and with the advantage of long experience, towards making himself understood; yet it is good for its main purpose. What they do, to reach mutual comprehension, is like what the first speechless men, unconsciously and infinitely more slowly, learned to do: face, hands, body, voice, are all put to use. It is altogether probable that gesture at first performed the principal part, even to such extent that the

earliest human language may be said to have been a language of gesture signs; indeed, there exist at the present day such gesture-languages as those in use between roving tribes of different speech that from time to time meet one another (the most noted example is that of the gesture-language, of a very considerable degree of development, of the prairie tribes of American Indians); or such signs as are the natural resort of those who by deafness are cut off from ordinary spoken intercourse with their fellows. Yet there never can have been a stage or period in which all the three instrumentalities were not put to use together. In fact, they are still all used together; that is even now an ineffective speaking to which grimace and gesture ("action," as Demosthenes called them) are not added as enforcers; and the lower the grade of development and culture of a language, the more important, even for intelligibility, is their addition. But voice has won to itself the chief and almost exclusive part in communication, insomuch that we call all communication "language" (i.e. "tonguiness") just as a race of mutes might call it "handiness" and talk (by gesture) of a handiness of grimace. This is not in the least because of any closer connection of the thinking apparatus with the muscles that act to produce audible sounds than with those that act to produce visible motions; not because there are natural uttered names for conceptions any more than natural gestured names. It is simply a case of "survival of the fittest," or analogous to the process by which iron has become the exclusive material of swords, and gold and silver of money: because, namely, experience has shown this to be the material best adapted to this special use. The advantages of voice are numerous and obvious. There is first its economy, as employing a mechanism that is available for little else, and leaving free for other purposes those indispensable instruments the hands. Then there is its superior perceptibleness: its nice differences impress themselves upon the sense at a distance at which visible motions become indistinct; they are not hidden by intervening objects; they allow the eyes of the listener as well as the hands of the speaker to be employed in other useful work; they are as plain in the dark as in the light; and they are able to catch and command the attention of one who is not to be reached in any other way. We might add as the third advantage a superior capability of variation and combination on the part of spoken sounds; but this is not to be insisted on, inasmuch as we hardly know what a gesture-language might have become if men's ingenuity in expression had been expended through all time upon its elaboration; and the superiority, however real, can hardly have been obvious enough to serve as a motive: certainly, there are spoken languages now existing whose abundance of resources falls short of what is attainable by gesture. Oral utterance is the form which expression has inevitably taken, the sum of man's endowments being what it is; but it would be a mistake to suppose that a necessity of any other kind is involved in their relation. The fundamental conditions of speech are man's grade of intellectual power and his social instinct; these being given, his expression follows, availing itself, as it were, to his purposes as voice was adapted to its purpose; if voice had been wanting it would have taken the next best. So, in certain well-known cases, a marked artistic gift on the part of individuals deprived of the use of hands has found means of exercise in the feet instead. But men in general have hands, instruments of exquisite tact and power, to serve the needs of their intellect; and so voice also, to provide and use the tools of thought; there is no error in maintaining that the voice is meant for speech, if only we do not proceed to draw from such a dictum false conclusions as to the relation between thought and utterance. Man is created with bodily instruments suited to do the work prescribed by his mental capacities; therein lies the harmony of his endowment.

It is through imitation that all signification becomes directly suggestive. The first written signs are (as already noticed) the depictions of visible objects, and could be nothing else; and, by the same necessity, the first uttered signs were the imitations of audible sounds. To reproduce
any sound of which the originating cause or the circumstances of production are known, brings up of course before the conception that sound, along with the originator, or circumstances of origination, or whatever else may be naturally associated with it. There are two special directions in which this mode of sign-making is fruitful: imitation of the sounds of external nature (as the cries of animals and the noises of inanimate objects when in motion or acted on by other objects) and imitation of human sounds. The two are essentially one in principle, although by some held apart, or even opposed to each other, as respectively the imitative or onomatopoetic and the exclamatory or interjectional beginnings of speech; they differ only in their spheres of significance, the one being especially suggestive of external objects, the other of inward feelings. There are natural human sounds associated with every feeling, and these sounds, modes of facial expression, which either are immediately intelligible to us (as is the warning cry of the hen to the day-old chicken), or have their value taught us by our earliest experiences. If we hear a cry of joy or a shriek of pain, a laugh or a groan, we need no explanation in words to tell us what it signifies any more than when we see a sad face or a drooping attitude. So also the characteristic cry or act of anything outside ourselves, if even rudely imitated, is to us an effective reminder and awakener of conception. We have no reason to question that such were the suggestions of the beginnings of uttered expression. The same means have made their contributions to language even down to our own day; we call words so produced “onomatopoetic” (i.e. “name-making”), after the example of the Greeks, who, when the original act of acts, new additions to language should be made in any other way. What and how wide the range of the imitative principle, and what amount of language-signs it was capable of yielding, is a subject for special investigation—or rather, of speculation, since anything like exact knowledge in regard to it will never be attained; and the matter is one of altogether secondary consequence; it is sufficient for our purpose that enough could certainly be won in this way to serve as the effective germs of speech.

All the natural means of expression are still at our command, and are put to more or less use by us, and their products are as intelligible to us as they have been to any generation of our ancestors, back to the very first. They are analogous to the sounds and motions of many animals; this, so far as we know, consists in observing and interpreting one another’s movements and natural sounds (where there are such). But language is a step beyond this, and different from it. To make language, the intent to signify must be present. A cry wrung out by pain, or a laugh of amusement, though intelligible, is not language; either of them, if consciously reproduced in order to signify to another pain or pleasure, is language. So a cough within hearing of any one attracts his attention; but to cough, or to produce any other sound, articulate or inarticulate, for the purpose of attracting another’s attention, is to commit an act of language-making, such as in human history preceded in abundance the establishment of definite traditional signs for conceptions. Here begins to appear the division between human language and all brute expression; since we do not know that any animal but man ever definitely took this step. It would be highly interesting to find out just how near any come to it; and to this point ought to be especially directed the attention of those who are investigating the communication of the lower animals in its relation to human communication. Among the animals of highest intelligence that associate with man and learn something of his ways, a certain amount of sign-making expressly for communication is not to be denied; the dog that barks at a door because he knows that somebody will come and let him in is an instance of it; perhaps, in wild life, the throwing out of sentinel birds from a flock, whose warning cry shall advertise their fellows of the threatened danger, is as near an approach to it as is anywhere made.

But the actual permanent beginnings of speech are only reached when the natural basis is still further abandoned, and signs begin to be used, not because their natural suggestiveness is seen in them, but by imitation, from the example of others who have been observed to use the same sign for the same purpose. Then for the first time the means of communication becomes something to be handed down, rather than made anew by each individual; it takes on that traditional character which is the essential character of all human institutions, which appears not less in the forms of social organization, the details of religious ceremonial, the methods of art and the arts, than in language. That all existing speech, and all known recorded speech, is purely traditional, cannot at all be questioned. It is proved even by the single fact that for any given conception there are, or have been, up to the midst of which the data of present or a thousand (this number is rather far within than beyond the truth), each of them intelligible to him who has learned to use it and to associate it with the conception to which it belongs, but unintelligible to the users of the nine hundred and ninety-nine other signs, as these are all unintelligible to him; unless, indeed, he learn a few of them also, even as at the beginning he learned the one that he calls his own. What single sign, and what set of signs, any individual shall use, depends upon the community into the midst of which he is cast, by birth or other circumstances, during his first years. That it does not depend upon his race is demonstrated by facts the most numerous and various; the African whose purity of descent is attested by every feature is found all over the world speaking just that language, or jargons, into the midst of which the data of present or a thousand have brought his parents; every civilized community contains elements of various lineage, combined into one by unity of speech; and instances are frequent enough where whole nations speak a tongue of which their ancestors knew nothing; for example, the Celtic Gauls and the Germanic Normans of France speak the dialect of a geographically insignificant district in central Italy, while we ourselves can hardly utter a sentence or write a line without bringing in more or less of that same dialect. There is not an item of any tongue of which we know anything that is “natural” expression, or to the possession of which its speaker is brought by birth instead of by education; there is even very little that is traceably founded on such natural expression; everywhere θῆς or human attribution remains, and even makes sense when the use of human language has disappeared and is only to be found by theoretic induction (as we have found it above). It seems to some as if a name like cuckoo (one of the most striking available cases of onomatopoëia) were a “natural” one; but there is just as much θῆς in it as in any other name; it implies the observation of an aggregate of qualities in a certain bird, and the selection of one among them as the convenient basis of a mutual understanding when the bird is in question; every animal conspicuous to us must have its designation, won in one way or another; and in this case to imitate the characteristic cry is the most available way. If anything but convenience and availability were involved, all our names for animals would have to be and to remain imitations of the sounds they make. That the name of cuckoo is applied during the egg-raying, and some other time of the year, during the nesting season, and then to related species which do not make the same sound—all helps to show the essentially conventional character of even this name. An analogous process of elimination of original meaning, and reduction to the value of conventional designation merely, is to be seen in every part of language throughout its whole history. Since men ceased to derive their names from signs having a natural suggestiveness, and began to make them from other names already in use with an understood value, every new name has had its etymology and its historical occasion—as, for example, the name quarantine from the two-score (quarantaine) of days of precautionary confinement, or volume from its being rolled up, or book from a beechwood staff, or copper from Cyprus, or lunacy from a fancied influence of the moon, or priest from being an older (spiritus) person, or butterfly from the butter-yellow colour of a certain
common species: every part of our language, as of every other, is full of such examples—but, when once the name is applied, it belongs to that to which it is applied, and no longer to its relatives by etymology; its origin is neglected, and its form may be gradually changed beyond recognition, or its meaning so far altered that comparison with the original shall seem a joke or an absurdity. This is a regular and essential part of the process of name-making in all human speech, and from the very beginning of the history of speech: in fact (as pointed out above), the latter can only be said to have begun when this process was successfully initiated, when uttered signs began to be, what they have ever since continued to be, conventional, or dependent only on a mutual understanding. Thus alone did language gain the capacity of unlimited growth and development. The sphere and scope of natural expression are narrowly bounded; but there is no end to the resources of conventional sign-making.

It is well to point out here that this change of the basis of men’s communication from natural suggestiveness to mutual understanding, and the consequent purely conventional character of all human language, in every part and particle, is an absolute line of demarcation between the latter and the means of communication of all the lower animals. The two are not of the same kind, any more than human society in its variety of organization is of the same kind with the instinctive herding of wild cattle or swarming of insects, any more than human architecture with the instinctive burrowing of the fox and nest-building of the bird, any more than human industry and accumulation of capital with the instinctive hoarding of bees and beavers. In all these cases alike the action of men is a result of the adaptation of means at hand to the satisfaction of felt needs, or of purposes dimly perceived at first, but growing clearer with gradually acquired experience. Man is the only being that has established institutions—gradually accumulated and perfected results of the exercise of powers analogous in kind to, but greatly differing in degree from, those of the lower animals. The difference in degree of endowment does not constitute the difference in language, it only leads to it. There was a time when all existing human beings were as cutaneous language as the dog; and that time would come again for any number of human beings who should be cut off (if that were practicable) from all instruction by their fellows: only they would at once proceed to recreate language, society and arts by the same steps by which their own remote ancestors created those which we now possess; while the dog would remain what he and his ancestors have always been, a creature of very superior intelligence, indeed, as compared with most, of infinite intelligence as compared with many, yet incapable of rising by the acquisition of culture through the formation and development of traditional institutions. There is just the same saltus existent in the difference between man’s conventional speech and the natural communication of the lower races as in that between men’s forms of society and the instinctive associations of the lower races; but it is no greater and no other; it’s neither more absolute and characteristic nor more difficult to explain. Hence those who put forward language as the distinction between man and the lower animals, and the latter upon our language as the same in kind with the means of communication of the lower animals, only much more complete and perfect, fail alike to comprehend the true nature of language, and are alike wrong in their arguments and conclusions. No addition to or multiplication of brute speech would make anything like human speech; the two are separated by a step which no animal below man has ever taken; and, on the other hand, language is only the most conspicuous among those institutions the development of which has constituted human progress, while their possession constitutes human culture.

With the question of the origin of man, whether or not developed out of lower animal forms, intermediate to the anthropoid apes, language has nothing to do, nor can its study ever be made to contribute anything to the solution of that question. If there once existed creatures above the apes and below man, who were extinguished by primitive man as his especial rivals in the struggle for existence, or became extinct in any other way, there is no difficulty in supposing them to have possessed forms of speech, more rudimentary and imperfect than ours. At any rate, all existing human speech is one in the essential characteristics which we have thus far noted or shall hereafter have to consider, even as humanity is one in its distinction from the lower animals; the differences are in non-essentials. All speech is one in the sense that every human being, of whatever race he may be, is capable of acquiring any existing tongue, and of using it for the same purposes for which its present possessors use it, with such power and effect as his individual capacity allows, and without any essential change in the mental operations carried on by means of speech—even as he may acquire any other of the items of culture belonging to a race not his own. The difference between employing one language and another is like that between employing one instrument and another in mechanical arts; one instrument may be better than another, and may enable its user to turn out better work, but the human ingenuity behind both is the same. For example: is a bird more of its kind when it can sing like a songbird than when it can only make a series of noise? Nor has the making of language anything whatever to do with making man what he is, as an animal species having a certain physical form and intellectual endowment. Being what he is by nature, man has by the development of language and other institutions become what he is by culture. His acquired culture is the necessary result of his native endowment, not the contrary. The acquisition of the first stumbling beginnings of a superior means of communication had no more influence to raise him from a simian to a human being than the present high culture and perfected speech of certain races has to lift them up to something more than human and specifically different from the races of inferior culture. It cannot be too absolutely laid down that differences of language, down to the possession of language at all, are differences only in respect to education and culture.

How long man, after he came into such being as he now is, physically and intellectually, continued to communicate with indicative signs of direct significance, when the production of traditional signs began, how rapidly they were accumulated, and how long any traces of their imitative origin clve to them—these and the like questions it is at present idle to try to answer even conjecturally: just as it is to seek to determine when the first instruments were used, how soon they were shaped instead of being left crude, at what epoch fire was reduced to service, and so on. The stages of development and their succession are clear enough; to fix their chronology will doubtless never be found practicable. There is much reason for holding, as some do, that the very first items of culture were hardest to win and cost most time, the rate of accumulation (as in the case of capital) increasing with the amount accumulated. Beyond all reasonable question, however, there was a positively long period of purely imitative signs, and a longer one of mixed imitative and traditional ones, the latter gradually gaining upon the former, before the present condition of things was reached, when the production of new signs by imitation is only spasmodic and of the utmost rarity, and all language-signs besides are traditional, their increase in any community being solely by variation and combination, and by borrowing from other communities.

Of what nature, in various respects, this earliest language-material was is sufficiently clear. The signs, in the first place, were of the sort that we call "roots." By this is only meant that they were integral signs, significant in their entirety, not divisible into parts, of which one signified one thing and another another thing, or of which one gave the main significance, while another was an added sign of kind or relation. In a language of developed structure like our own, we arrive at such "roots" mainly by an artificial stripping-off of the signs of relation which almost every word still has, or can be shown to have once had. In un-cost-I-ness, for example, cost is the centrally significant element; so far as English is
concerned it is a root, about which cluster a whole body of forms and derivatives; if we could follow its history no farther it would be to us an ultimate root, as much so as bind or sing or mean. But we can follow it up, to the Latin compound con-sta, a root sta with a prefixed formative element con. Then sta, which in slightly varied forms we find in a whole body of related tongues called "Indo-European," having in them all the same significance "stand," is an Indo-European root, and to us an ultimate one, because we can follow its history no farther; but there always remains the possibility that it is as far from being actually original as is the English root cost: that is to say, it is not within our power ever to get back to the really primitive elements of speech and to demonstrate their character by positive evidence. The reason for accepting a primitive root-stage of language is in great part theoretical: because nothing else is reconcilable with any acceptable view of the origin of language. The law of the simplicity of beginnings is an absolute one for everything of the nature of an institution, for every gradually developed product of the exercise of human faculties. That an original speech-sign should be of double character, one part of it meaning this and another part that, or one part radical and the other formative, is as inconceivable as that the first instruments should have had handles, or the first shelters a front room and a back one. But this theoretical reason finds all the historical support which it needs in the fact that, through all the observable periods of language-history we see formative elements coming from words originally independent, and not from anything else. Thus, in the example just taken, the -li-of costliness is a suffix of so recent growth that its whole history is distinctly traceable; it is simply our adjective like, worn down in both form and meaning to a subordinate value in combination with certain words to which it was appended, and then added freely as a suffix to any word from which it was desired to make a derivative adjective—or, later but more often, a derivative adverb. The ness is much older (though only Germanic), and its history obscure; it contains, in fact, two parts, neither of them of demonstrable origin; but there are equivalent later suffixes, as ship in hardship and dom in wisdom, whose derivation from independent words (shape, doom) is beyond question. The un-of uncostliness is still more ancient (being Indo-European), and its probably formal origin hardly available as an illustration; but the comparatively modern prefix be-, of become, befe, &c., comes from the independent preposition by, by the same process as -ly or -li-from like. And the cost which has contributed its part to the making of the costliness is shown in origin identical with the Latin preposition cum, "with." By all the known facts of later language-growth we are driven to the opinion that every formative element goes back to some previously existing independent word; and hence that in analysing our present words we are retracing the steps of an earlier synthesis, or following up the history of our formed words toward the unformed roots out of which they have grown. The doctrine of the historical growth of language-structure leads by a logical necessity to that of a root-stage in the history of all language; the only means of avoiding the latter is the assumption of a miraculous element in the former.

Of what phonetic form were the earliest traditional speech-signs is, so far as essentials are concerned, to be inferred with reasonable certainty. They were doubtless articulate: that is to say, composed of alternating consonant and vowel sounds, like our present speech; and they probably contained a part of the same sounds which we now use. All human language is of this character; there are no sounds in any tongue which are not learned and reproduced as easily by children of one race as of another; all dialects admit a like phonetic analysis, and are representable by alphabetic signs; and the leading sounds, consonant and vowel, are even practically the same in all; though every dialect has its own (for the most part, readily definable and imitable) niceties of their pronunciation, while certain sounds are rare, or even met with only in a single group of languages or in a single language. Articulate sounds are such as are capable of being combined with others into that succession of distinct yet connectable syllables which is the characteristic of human speech-utterance. The name "articulate" belongs to this utterance, as distinguished from inarticulate human sounds and cries and from the sounds made by the lower animals. The word itself is Latin, by translation from the Greek, and, though very widely misunderstood, and even deliberately misapplied in some languages to designate all sound, of whatever kind, uttered by any living creature, is a most happily chosen and truly descriptive term. It signifies "jointed," or broken up into successive parts, like a limb or stem; the joints are the syllables; and the syllabic structure is mainly effected by the alternation of closer or consonant sounds with opener or vowel sounds. The simplest syllabic combination (as the facts of language show) is that of a single consonant with a following vowel; and there are languages even now existing which reject any other. Hence there is much plausibility in the view that the first speech-signs will have had this phonetic form and been monosyllabic, or disyllabic only by repetition (reduplication) of one syllable, such as the speech of very young children shows to have a peculiar ease and naturalness. The point, however, is one of only secondary importance, and may be left to the further progress of phonetic study to settle, if it can; the root-theory, however, is not bound to any definite form or extent of root, but only denies that there can have been an ungrammatical structure in language except by development in connexion with experience in the use of language. What particular sounds, and how many, made up the first spoken alphabet is also a matter of conjecture merely; they are likely to have been the closest consonants and the openest vowels, medial utterances being of later development.

As regards their significant value, the first language-signs must have denoted those physical acts and qualities which are directly apprehensible by the senses; both because these alone are directly signifiable, and because it was only they that untrained human beings had the power to deal with or the occasion to use. Such signs would then be applied to more intellectual uses as fast as there was occasion for it. The whole history of language, down to our own day, is full of examples of the reduction of physical terms and phrases to the expression of non-physical conceptions and relations; we can hardly write a line without giving illustrations of this kind of linguistic growth. So pervading is it, that we never regard ourselves as having read the history of any physical or moral term till we have traced it back to a physical or moral origin. And we are still all the time drawing figurative comparisons between material and moral things and processes, and calling the latter by the names of the former. There has never been any difficulty in providing for new knowledge and more refined thought by putting to new uses the earlier and grosser materials of speech.

As a matter of course, whatever we now signify by our simple expressions for simple acts, wants, and the like, was intended to be signified through the first speech-signs by the users of them. But to us, with our elaborated apparatus of speech, the sentence, composed of subject and predicate, with a verb or special predicative word to signify the predication, is established as the norm of expression, and we regard everything else as an abbreviated sentence, or as involving a virtual sentence. With a view to this we must have "parts of speech": that is, words held apart in office from one another, each usable for such and such a purpose and no other, and answering a due variety of purposes, so that when they are combined they fit together, as parts composing a whole, and the desired meaning is made clear. Inflections, too, lend the same aid; or else auxiliary words of various kinds answering the same purpose—namely, of determining the relations of the members of the sentence. But all our success in understanding the earliest stages of language depends upon our power to conceive a state of things where none of these distinctions were established, where one speech-sign was like another, calling up a conception in its indefinite entirety, and leaving the circumstances of the case to limit its application.
PHILOLOGY

420

Such a language is far below ours in explicitness; but it would suffice for a great deal of successful communication; indeed (as will be shown farther on) there are many languages even now in existence which are little better off. So a look of approval or disapproval, a gesture of beckoning or repulsion, a grunt of assent or inquiry, is as significant as a sentence, means a sentence, is translatable into a sentence, and hence may even in a certain way be called a sentence; and in the same way, but only so, the original roots of language may be said to have been sentences. In point of fact, between the holophrastic gesture or uttered sign and the sentence which we can now substitute for it—for example between the sign of beckoning and the equivalent sentence, “I want you to come here”—lies the whole history of development of instructive speech. What has been this history of development, how the first scanty and formless signs have been changed into the immense variety and fullness of existing speech, is of course impossible to point out in detail, or by demonstration of facts, because nearly the whole process is hidden in the darkness of an imperceptible past. The only way to cast any light upon it is by careful induction from the change and growth which are seen to have been going on in the recent periods for which we have recorded evidence, or which are going on at the present time. Of some groups of related languages we can read the life for three or four thousand years back, and by comparison can infer it much farther; and the knowledge thus won is what we have to apply to the explanation of periods and languages otherwise unknown. Nothing has a right to be admitted as a factor in language-growth of which the action is not demonstrable in recorded language. Our own family of languages is the one of whose development most is known, by observation and well-warranted inference; and it may be well here to sketch the most important features of its history, by way of general illustration.

Apparently the earliest class-distinction traceable in Indo-European speech is that of pronominal roots, or signs of position, from the more general mass of roots. It is not a formal distinction, marked by a structural difference, but, so far as can be seen, is founded only on the assignment by usage of certain elements to certain offices. Formal distinction began with combination, the addition of one element to another, their fusion into a single word, and the reduction of the one part to a subordinate value, as sign of a certain modification of meaning of the other. Thus, doubtless by endings of pronominal origin, were made the first verb-forms, or words used only when predication was intended (since that is all that makes a verb), conveying at first a distinction of persons only, then of persons and numbers, while the further distinction of tense and mode were by degrees added. To the nouns, which became nouns by the setting up of the separate and special class of verbs, were added in like manner distinctions of case, of number, and of gender. With the separation of noun and verb, and the establishment of their respective inflexion, the creative work of language-making is virtually done; the rest is a matter of differentiation of uses. For the noun (noun substantive) and the adjective (noun adjective) become two parts of speech only by a gradually deepened separation of use; there is no original or formal distinction between them; the pronouns as a rule merely add the noun-inflexion to a special set of stems; adverbs are a part of the same formation as nouns—cases; prepositions are adverbs with a specialized construction, of secondary growth; conjunctions are the products of a like specialization; articles, where found at all, are merely weakened demonstratives and numerals.

To the process of form-making, as exhibited in this history, belong two parts: the one external, consisting in the addition of one existing element of speech to their combination into a single word; the other internal, consisting in the adaptation of the compound to its special use and involving the subordination of one element to the other. Both parts appear also abundantly in other departments of language-change, and throughout the whole history of our languages; nothing has to be assumed for the earliest formations which is not plainly illustrated in the latest. For example, the last important addition to the formative apparatus of English is the common adverb-making suffix -ly, coming, as already pointed out, from the independent adjective like. There was nothing at first to distinguish a compound like godly (godlike) from one like storm-tossed, save that the former was more adaptable than the other to wider uses; resemblance is an idea easily generalized into appurtenance and the like, and the conversion of godlike to godly is a simple result of the processes of phonetic change described farther on. The extension of the same element to combination with adjectives instead of nouns, and its conversion to adverb-making value, is a much more striking case of adaptation, and is nearly limited to English among the Germanic languages that have turned like into a suffix. A similar striking case of combination and adaptation is seen in the Romanic adverb-making suffix mente or ment, coming from the Latin ablative mente, “with mind.” So, to make a Romanic future like donnerai, “I shall give,” there was needed in the first place the pre-existing elements, donner, “to give,” and ai, “I have,” and their combination; but this is only a part; the other indispensable part is the gradual adaptation of a phrase meaning “I have [something before me] for giving” to the expression of simple futurity, donabo. So far as the adaptation is concerned the case is quite parallel to that of j’ai donné, “I have given,” &c. (equivalent phrases or combinations are found in many languages), where the expression of possession of something that is acted on has been in like manner modified into the expression of past action. Parallel in both combination and adaptation is the past tense loved, according to a widely accepted theory, from love-did, while we have again the same adaptation without combination in the equivalent phrase did love.

That these are examples of the process by which the whole instructive structure of Indo-European language was built up admits of no reasonable question. Our belief that it is so rests upon the solid foundation that we can demonstrate no other process, and that this one is sufficient. It is true that we can prove such an origin for our formative elements in only a small minority of instances; but this is just what was to be expected, considering what we know of the disguising processes of language-growth. No one would guess in the mere y of ably (for able-ly) the presence of the adjective like, any more than in the altered final of sent and the shortened vowel of led the effect of a did once added to send and lead. The true history of these forms can be shown, because there happen to be other facts left in existence to show it; where such facts are not within reach we are left to infer by analogy from the known to the unknown. The validity of our inference can only be shaken by showing that there are formative elements incapable of having been made in this way, or that there are and have been other ways of making forms. Of the former there is evidently but small chance; if a noun-form meaning, “with mind” can become the means of conversion of all the adjectives of a language into adverbs, and a verb meaning “have” (and, yet earlier, “seize”) of signifying both future and past time, there is obviously nothing that is impossible of attainment by such means. As regards the latter, no one appears to have even attempted to demonstrate the genesis of formative elements in any other way during the historical periods of language; it is simply assumed that the early methods of language-making will have been something different from and superior in spontaneity and fruitfulness to the later ones; that certain forms, or forms at certain periods, were made out-and-out, as forms; that signs of formal distinction somehow exuded from roots that original words were merely remembered, and that a formative value settled in some member of them—and the like. Such doctrines are purely fanciful, and so opposed to the teachings both of observation and of sound theory that the epistle absurd is hardly too strong to apply to them. If the later races, of developed intelligence, and trained in the methods of a fuller expression, can only win a new form by a long and gradual process of combination and adaptation, why should the earlier and comparatively untrained generations have been able to do any
better? The advantage ought to be, if anywhere, on our side.

The progress of language in every department, accompanying and representing the advance of the race, on the whole, in the art of speaking as in other arts, is from the grosser to the more refined, from the physical to the moral and intellectual, from the material to the formal. The conversion of compounds into forms, by the reduction of one of their elements to formative value, is simply a part of the general process which also creates auxiliaries and form-words and connectives, all the vocabulary of mind, and all the figurative phraseology that gives life and vigour to our speech. If a copula, expressive of the grammatical relation of predication, could be won only by attenuation of the meaning of verbs signifying "grow," "breathe," "stand," and the like; if our auxiliaries of tense and mode all go traceably back to words of physical meaning (as have to "seize," may to "be great or strong," shall to "be under penalty," and so on); if of comes from the comparatively physical off, and for from "before, forward"; if relative pronouns are specialized demonstratives and interrogatives; if right means etymologically "straight," and wrong means "twisted"; if spirit is "blowing," and intellect a "picking out among," and understanding a "getting beneath," and development an "unfolding"; if an event takes place or comes to pass, and then drops out of mind and is forgotten (opposite of gotten)—then it is of no avail to object to the grossness of any of the processes by which, in earlier language or in later, the expression of formal relations is won. The mental sense of the relation expressed is entirely superior to and independent of the means of its expression. He who, to express the plural of man, says what is equivalent to man-man or heap-man (devices which are met with in not a few languages) has just as good a sense of plurality as he who says men or homines; that sense is no more degraded in him by the coarseness of the phrase he uses to signify it than is our own sense of eventuality and of pastness by the undisguised coarseness of take place and have been. In short, it is to be laid down with the utmost distinctness and confidence, as a law of language-growth, that there is nothing formal anywhere in language which was not once material; that the formal is made out of the material, by processes which began in the earliest history of language and are still in action.

We have dropped here the restriction to our own or Indo-European language with which we began, because it is evident that what is true of this family of speech, one of the most highly organized that exists, may at least be true of them, unless some valid evidence be found to the contrary. The unity of human nature makes human speech alike in the character of its beginnings and in the general features of its after-history. Everywhere among men a certain store of expression, body of traditional signs of thought, being given, as used by a certain community, it is capable of increase on certain accordant lines, and only on them. In some languages, and under peculiar circumstances, borrowing is a great means of increase; but it is the most external and least organically important of all. Out-and-out invention (which, so far as we can see, must be of the kind called by us onomatopoetic) is found to play only a very insignificant part in the historical periods of language—clearly because there are other and easier modes of gaining new expression for what needs to be expressed. In the course of phonetic change a word sometimes varies into two (or more) forms, and makes so many words, which are differently turned to account. Everything beyond this must be the product of combination; there is no other way, so far as concerns the externals of speech. Then, partly as accompanying and aiding this external growth, partly as separate from and supplementing it, there is in all language an internal growth, making no appearance in the audible part of speech, consisting in multiplication of meanings, their modification in the way of precision or comprehension or correctness, the restriction of words to certain uses, and so on. Along with these, too, a constant change of phonetic form constitutes an inseparable part of the life of language. Speech is no more stable with respect to the sounds of which it is composed than with respect to its grammatical forms, its vocabulary, or the body of conceptions signified by it. Even nearly related languages differ as much in their spoken alphabets and the combinations of sounds they admit, and in their uttered forms of words historically the same, as in any other part; and the same is true of local dialects and of class dialects within the same community. Phonetic change has nothing whatever to do with change of meaning; the two are the product of wholly independent tendencies. Sometimes, indeed, they chance to coincide, as in the distinction of minute "small," and minute "moment"; but it is only by chance, as the spoken accordance of second in its two meanings ("next" and "sixtieth of a minute") shows; words that maintain their identity of value most obstinately, like the numerals, are liable to vary indefinitely in form (so four, fōr, quatuor, τέτρα, &c., from an original first-, four-, quarto-, &c.—Penkter—while, on the other hand, two and three show as striking an accordance of form as of meaning through all the same languages); what is far the most common is that the word becomes very unlike its former self in both respects, like priest from the Greek πρεσβύτερος (presbyter), literally "older man." Human convenience is, to be sure, the governing motive in both changes; but it is convenience of two different kinds: the one mental, depending on the fact (pointed out above) that a name when once applied belongs to the thing to which it is applied, to the disregard of its etymological connexions, does not need to be changed when the thing changes, and is ready for new application to anything that can be brought into one class with the latter; and the other physical, depending on the organs of speech and their successive movements, by which the sounds that make up the word are produced. Phonetic convenience is the economy of effort on the part of those organs; and to no other law than that of economy of utterance have any of the phenomena of phonetic change been found traceable (though it is also to be noted that some phenomena have not hitherto been successfully brought under it, and that the way of effecting this is still unclear). "Euphony," which used to be appealed to as explanation, is a false principle, except so far as the term may be made an idealized synonym of economy. The ear finds that agreeable which the organs of utterance find facile. Economy in utterance is no isolated tendency; it is the same that plays its part in all other kinds of human action, and in language appears equally in the abbreviation of the sentence by leaving out parts that can be spared without loss of intelligibility. It is an insidious tendency, and always has been, that is not sufficiently held up—the holding-up force in language being the faithfulness of tradition, or accurate reproduction by the learner and user of the signs which he has acquired. No generation of men has any intention to speak otherwise than as its predecessor has spoken, or any consciousness that it is doing so; and yet, from generation to generation, words are shortened, sounds are assimilated to one another, and one element passes out of use while a new one is introduced. Abbreviation and assimilation are the most conspicuous departments of phonetic change, and those in which the nature of the governing tendency is most plainly seen. Taken by itself, one sound is as easy as another to the person who has accustomed himself to it from childhood; and those which the young child most easily acquires are not those with which the history of speech are least liable to alteration; it is especially in the combinations and transitions of rapid speaking that the tongue, as it were, finds out for itself easier ways of performing its task, by dropping and slurring and adapting. To trace out the infinitely varied items of this change, to co-ordinate and compare them and discover their reasons, constitutes a special department of language-study, which is treated under the head of PHONETICS. It only needs to be pointed out here that phonetic change plays a necessary part in the structural development of language, by integrating compound words through fusion and loss of identity of their component parts, and, what is of yet more importance, by converting them into forms, through disguise of identity of one of the parts and its phonetic subordination to the other part. It is this that turns, for example, the compound god-like into PHILIOLOGY 421
the derivative godly, the compound loved did into the verbal form loved. And yet one further result sometimes follows: an internal change is wrought by phonetic influence in the body of a word, which change then may in the further history edy of the word be left as the sole means of distinction between one form and another. It is thus that, in the most recent period, the distinction of led from lead and met from meet and so on has been made; the added auxiliary which originally made these preterites induced a shortening of the root-vowel, and this was left behind when the auxiliary disappeared by the usual process of abbrevia-
tion. It is in the same way that the distinctions of men from man, were from was, of set from sit, with all their analogues, were brought about: by a modification of vowel-sound (Ger. Umlaus) occasioned by the presence in the following syllable of an i-vowel, in the older stages of the language is still to be seen there. And the distinctions of sing, sung, sung and song, of bind, bound, band and bond, are certainly of the same kind, though they go back so far in the history of our family of languages that their beginnings are not yet clearly demonstrable; they were in their origin phonetic accidents, inorganic, mere accompaniments and results of external combinations which bore the office of distinction of meaning and were sufficient to it; in some of the languages they have been disregarded and displaced, in others they have risen to prominent importance. To regard these internal changes as primary and organic is parallel with assuming the primernity of the formative apparatus of language in general; like this, it ignores the positive evidence we have of the secondary production of such differences; they are, like everything else in linguistic structure, the outcome of combination and adaptation.

Borrowing, or the taking-in of material out of another language, has been more than once referred to above as sometimes an important element in language-history, though less deep-reaching and organic than the rest. There is nothing anomalous about borrowing; it is rather in essential accordance with the whole process of language-acquisition. All our names were adopted by us because they were already in use by others; and a community in the same way capable of taking a new name from a community with which it comes in contact as an individual from individuals. Not that it seeks or admits in this way new names for old things; but it accepts new things along with the names that seem to belong to them. Hence any degree of intercourse between one community and another, leads to an exchange of products or of knowledge, is sure to lead also to some borrowing of names; and there is hardly a language in the world, except of races occupying peculiarly isolated positions, that does not contain a certain amount of foreign material thus won, even as our English has elements in its vocabulary from half the other tongues in the world. The scale of borrowing is greatly increased when one people becomes the pupil of another in respect of its civilization: hence the abundant classical elements in all the European tongues, even the non-Romantic; hence the Arabic material in Persian and Turkish and Malay; hence the Chinese in Japanese and Corean; and, as a further result, even dead languages, like the Greek and Latin and the Sanskrit, become stores to be drawn upon in that learned and conscious quest of new expression which in the school-stage of culture supplements or even in a measure replaces the unconscious growth of natural languages. So, in mixture of communities, which is a highly intensified form of contact and intercourse, there follows such mixture of speech as the conditions of the case determine; yet not a mixture on equal terms, through all the departments of vocabulary and grammar; the resulting speech (just as when two individuals learn to speak alike) is essentially that of the one constituent of the new community, with more or less material borrowed from that of the other. What is most easily taken in out of another language is the names of concrete things; every degree of removal from this involves additional difficulty—names of abstract things, epithets, verbs, connectives, forms. Indeed, the borrow-
ing of forms in the highest sense, or forms of inflexion, is well-nigh or quite impossible; no example of it has been demonstrated in any of the historical periods of language, though it is some-
times adventurously assumed as a part of prehistoric growth. How nearly it may be approached is instanced by the presence in English of such learned plurals as phænomena and stræta. This extreme resistance to mixture in the department of inflexion is the ground on which some deny the possibility of mixture in language, and hence the existence of such a thing as a mixed language. The difference is mainly a verbal one; but it would seem about as reasonable to deny that a region is inundated so long as the tops of its highest mountains are above water. According to the simple and natural meaning of the term, nearly all languages are mixed, in varying degree and within varying limits, which the circumstances of each case must explain.

These are the leading processes of change seen at work in all present speech and in all known past speech, and hence to be regarded as having worked through the whole history of speech. By their operation every existing tongue has been developed out of its rudimentary radical condition to that in which we now see it. The variety of existing languages is well-high infinite, not only in their material but in their degree of development and the kind of resulting structure. Just as the earlier stages in the history of the use of tools are exemplified even at the present day by races which have never advanced beyond them, so is it in regard to language also—
and, of course, in the latter case as in the former, this state of things strengthens and establishes the theory of a gradual development. There is not an element of linguistic structure possessed by some languages which is not wanting in others; and there are even tongues which have no Languages,
formal structure, and which cannot be shown ever
to have advanced out of the radical stage. The most noted example of such a rudimentary tongue is the Chinese, which in its present condition lacks all formal distinction of the parts of speech, all inflexion, all derivation; each of its words (all of them monosyllables) is an integral sign, not divisible into parts of separate significance; and each in general is usable wherever the radical idea is wanted, with the value of one part of speech or another, as determined by the connexion in which it stands; a condition parallel with that in which Indo-European speech may be regarded as existing prior to the beginnings of its career of formal development briefly sketched above. And there are other tongues, related and unrelated to Chinese, of which the same description, or one nearly like it, might be given. To call such languages radical is by no means to maintain that they exhibit the primordial roots of human speech, unchanged or only phonetically changed, or that they have known nothing of the combination of element with element. Of some of them the roots are in greater or less part dissyllabic; and we do not yet know that all dis-
 syllalism, and even that all complexity of syllable beyond a single consonant with following vowel, is not the result of comination or reduplication. But all combination is not form-making; it needs a whole class of combinations, with a recognized common element in them producing a recognized common modification of meaning, to make a form. The same elements which (in Latin, and even in English also) are of formal value in constant and pro-did lack that character in cost and preach; the same like which makes adverbs in tru-ly and right-ly present without any such value in such and which (from so-like and who-like); cost and preach, and such and which, are as purely radical in English as other words of which we do not happen to be able to demonstrate the composite character. And so a Chinese monosyllable or an Egyptian or Polynesian dissyllable is radical, unless there can be demonstrated in some part of it a formative value; and a language wholly composed of such words is a root-language. Recent investigation goes to show that Chinese had at some period of its history a formal development, since extinguished by the same processes of phonetic decay which in English have wiped out so many signs of a formal character and brought back so considerable a part of the vocabulary to monosyllabism. In languages thus constituted the only possible external alteration is that phonetic change to which all human speech, from the
Every tongue represents the general outcome of the capacity of a race as exerted in this particular direction, under the influence of historical circumstances which we can have no hope of tracing. There are striking apparent anomalies to be noted. The Chinese and the Egyptians have shown themselves to be among the most gifted races the earth has known; but the Chinese tongue is of unsurpassed jeuness, and the Egyptian, in point of structure, little better, while among the wild tribes of Africa and America we find tongues of every grade, up to a high one, or to the highest. This shows clearly enough that mental power is not measured by language-structure. But any other linguistic test would prove equally insufficient. On the whole, the value and rank of a language are determined by what its users have made it do. The reflex action of its speech on the mind and culture of a people is a theme of high interest, but of extreme difficulty, and apt to lead its investigators away into empty declamation; taking everything together, its amount, as is shown by the instances already referred to, is but small. The question is simply one of the facilitation of work by the use of one set of tools rather than another; and a poor tool in skillful hands can do vastly better work than the best tool in unskilful hands—even as the ancient Egyptians, without steel or steam, turned out products which, both for colossal grandeur and for exquisite finish, are the despair of modern engineers and artists. In such a history of development as that of human speech a fortunate turn may lead to results of unforeseen value; the earlier steps determine the later in a degree quite beyond their own intrinsic importance. Everything in language depends upon habit and analogy; and the formation of habit is a slow process, while the habit once formed exercises a constraining as well as a guiding influence. Hence the persistency of language-structure: when a certain sum and kind of expression is produced, and made to answer the purposes of expression, it remains the same by inertia; a shift of direction becomes of extreme difficulty. No other reason can at present be given why in historical time there has been no marked development out of one grade of structure into another; but the fact no more shakes the linguistic scholar's belief in the growth of structure than the absence of new animal species worked out under his eyes shakes the confidence of the believer in animal development. The modifying causes and their modes of action are clearly seen, and there is no limit to the results of their action except what is imposed by circumstances.

It is in vain to attempt to use dates in language-history, to say when this or that step in development was taken, and how long a period it cost, especially now that the changed views as to the antiquity of man are making it probable that only a small part of the whole history is brought within the reach even of our deductions from the most ancient recorded dialects. At any rate, for aught that we know or have reason to believe, all existing dialects are equally old; every one alike has the whole immeasurable past of language-life behind it, has reached its present condition by advance along its own line of growth and change from the first signs of expression. Many of these separate lines we clearly see to converge, yet not to unite, as we follow them back into the past; but whether they all ultimately converge to one point is a question quite beyond our power to answer. If in this immensity of time many languages have won so little, if everywhere language-growth has been so slow, then we can only differ as to whether it is reasonably certain, or probable, or only possible, that there should have been a considerable first period of human existence without traditional speech, and a yet more considerable one before the fixation of so much as should leave abiding traces in its descendants, and that meanwhile the race should have multiplied and scattered into independent communities. And the mere possibility is enough to exclude all dogmatic assertion of the unity of origin of human speech, even assuming unity of origin of the human race. For to prove that identity by the still existing facts of language is utterly out of the question;
the metamorphosing effect of constant change has been too great to allow it. In point of fact, taking languages as they now exist, only those have been shown related which possess a common structure, or have together grown out of the more primitive radical stage, since structure proves itself a more constant and reliable evidence than material. And this is likely ever to be the case; at any rate, to trace all the world's languages so far back toward their beginnings as to find in them evidences of identity is beyond the wildest hope. We must be content with demonstrating for those beginnings a unity of kind as alike a body of formless roots. But, on the other hand, since this unity is really demonstrated, since all structure is the result of growth, and no degree of difference of structure, any more than of difference of material, refutes explanation as the result of discordant growth from identical beginnings, it is equally inadmissible to claim that the diversities of language prove it to have had different beginnings. That is to say, the question of the unity of speech, and yet more that of the unity of the race, is beyond the reach of the student of language; the best view he can attain is the hypothetical one, that, if the race is one, the beginnings of speech were perhaps one—but probably not, even then. This negative conclusion is so clearly established as to leave no excuse for the still oft-repeated attempts to press language into service on either side of the controversy respecting human unity of race.

That all making and changing of language is by the act of its speakers is too obvious to call for discussion. No other force capable of acting and of producing effects is either demonstrable or conceivable as concerned in the work. The doctrine that language is an organism, growing by its own inherent powers, exempt from the interference of those who use it, is simply an indefensible paradox. Every word that is uttered is so by an act of human will, at first in imitation of others, then more and more by a formed and controlling habit; it is accessible to no change except by influences working in the speaker's mind and leading him to make it otherwise. Not that he is aware of this, or directs his action knowingly to that end. The whole process is unconscious. If any implication of reflective or intended action can be shown to inhare in any doctrine of linguistic science, it vitiates that doctrine. The attitude of the ordinary speaker towards his language is that of unreasoning acceptance; it seems to him that his names for things are their real names, and all others unintelligent nicknames; he thinks himself to possess his speech by the same tenure as his sight or hearing; it is "natural" to him (or, if he reasons about it, he attributes it to a divine origin, as races beginning to philosophize are wont to ascribe their various social institutions to their gods); he knows nothing of its structure and relations; it never occurs to him to find fault with it, or to deem it insufficient and add to or change it; he is wholly unaware that it does change. He simply satisfies his social needs of communication by means of it; and if he has anything to express that is different from what has been expressed before, he takes the shortest way to a provision for the need; while any relaxation of the energy of utterance tends to a variation in the uttered combinations; and thus changes come by his act, though without his knowledge. His sole object is, on the basis of what language he has, to make known his thought in the most convenient way to his fellow; everything else follows with and from that. Human nature and circumstances being what they are, what follows actually is, as already shown, incessant growth and change. For it would be too soon to seek special disturbing causes in the history of the peoples, although such may come in to heighten and quicken the change; we know that even in a small community, on a narrow islet, cut off from all intercourse with other communities, the speech would grow different—as certainly, if not as rapidly, as anywhere in the world—and only by the action of its speakers: not that the speakers of a language act in unison and simultaneously to produce a given change. This must begin in an individual, or more or less accordantly in a limited number of individuals and spread from such example through the community. Initiation by one or a few, acceptance and adoption by the rest—such is the necessary method of all linguistic change, and to be read as plainly in the facts of change now going on among ourselves as in those of former language. The doctrine of the inaccessibility of language to other action than that of its speakers does not imply a power in the individual speaker to create or alter anything in the common speech, any more than it implies his desire to do so. What he suggests by his example must be approved by the imitation of his fellows, in order to become language. The common speech is the common property, and no one person has any more power over it than another. If there are, for example, a thousand speakers of a certain dialect, each one wields in general a thousandth part of the force required to change it—with just so much more as may belong to his excess of influence over his fellows, due to recognized superiority of any kind on his part. His action is limited only by their assent; but this is in effect a very narrow limitation, ensuring the adoption of nothing that is not in near accordance with the already existing; though it also is to be noted that he is as little apt to strike off into startling change as they to allow it; since the governing power of already formed habits of speech is as strong in him as in them. That change to which the existing habits naturally lead is easy to bring about; any other is practically impossible. It is this tendency on the part of the collective speakers of a language to approve or reject a proposed change according to its conformity with their already subsisting usages that we are accustomed to call by the fanciful name "the genius of a language."

On the relation of the part played in language-change by the individual to that by the community, in combination with the inevitability of change, rests the explanation of the dialectic variation of language. If language were demonstrable there would of course be no divarication; but since it is always varying, and by items of difference that proceed from individuals and become general by diffusion, there can be uniformity of change only so far as diffusion goes or as the influences of communication extend. Within the limits of a single community, small or large, whatever change arises spreads gradually to all, and so becomes part of the general speech; but let that community become divided into two (or more) parts, and then the changes arising in either part do not spread to the other, and there begins to appear a difference in linguistic usage between them. It is at first slight, even to insignificance; not greater than exists between the dialects of different localities or ranks or occupations in the same community, without detriment to the general unity of speech. This unity, namely, rests solely on mutual intelligibility, and is compatible with no small amount of individual and class difference, in vocabulary, in grammar and in pronunciation; indeed, in the strictest sense, each individual has a dialect of his own, different from that of every other, even as he has a handwriting, a countenance, a character of his own. And every item of change, as it takes place, must have its season of existence as a local or class or trade peculiarity, before it gains universal currency; some of them linger long in that condition, or never emerge from it. All these differences in the speech of different sub-communities within the same community are essentially dialectic; they differ not in kind, but only in degree, from those which separate the best-marked dialects; they are kept down by general communication within the limit of general mutual intelligibility. Where that restraining influence ceases the limit is gradually but surely overpassed, and real dialects are the result. From the very nature of the life of language we can say positively that continued uniformity of speech without continued community is not practicable. If it were possible to divide artificially, by an impassable chasm or wall, a people one for ages, and continuing to occupy the same seats, the language of the divided parts would at once begin to be dialectically different; and after sufficient time had elapsed each would have become unintelligible to the other. That is to say, whenever a community of uniform speech breaks up, its speech breaks
up also; nor do we know of any other cause of dialectic diversity.

In applying this explanation of dialectic growth we have to allow for modifying circumstances of various nature, which alter not indeed the fact but the rate and kind of diverication. Some languages grow and change much more rapidly than others, with a corresponding effect upon diverication, since this is but a result of discordant growth. Usually, when there is division of a community, the parts get into different external circumstances, come in contact or mingle with different neighbouring communities, and the like; and this quickens and increases their divergence of speech. The modifying factors of by far the highest importance here, as elsewhere in the history of language, is civilization. Civilization in its higher forms so multiplies the forces of communication as to render it possible that the widely-divided parts of one people, living in circumstances and under institutions of very different character, should yet maintain a substantial oneness of speech; or that there is no more striking example than the two great divisions of the English-speaking people on opposite sides of the Atlantic. On the other hand, a savage people cannot spread even a little without dialectic disunity; there are abundant examples to be met with now of mutually unintelligible speech between the smallest subdivisions of a race of obviously kindred tongue— as the different clusters of huts on the same coral islet. It is with linguistic unity precisely as it is with political unity, and for the same reasons. Before the attainment of civilization the human race, whether proceeding from one centre of dispersion or from several, was spread over the earth in a state of utter disintegration; but every centre of civilization becomes also a centre of integration; its influences make for unity of speech as of all other social institutions. Since culture has become incontestably the dominant power in human life, the unifying forces in language have been stronger than the diversifying; and with culture at its full height, and spread equally to every land and race, one universal language, like one universal community, is not an absurdity or theoretic impossibility, but only a Utopian or millennial dream.

Dialectic variation is thus simply a consequence of the movements of population. As the original human race or races, so the divisions or communities of later formation, from point to point through the whole life of man on the earth, have spread and separated, but jostled and interfered, have conquered and exterminated or mingled and absorbed; and their speech has been affected accordingly. Hence something of these movements can be read in the present condition of languages, as in a faithful though obscure record—more, doubtless, than can be read in any other way; however little it may be, it is sound absolutely. Dialectic resemblance point inevitably back to an earlier unity of speech, and hence of community; from what we know of the history of speech, they are not to be accounted for in any other way. The longer the separation that has produced the diversity, the greater its degree. With every generation the amount of accordance decreases and that of discordance increases the common origin of the dialects is at first palpable, then evident on examination, then to be made out by skilled research, then perhaps no longer demonstrable at all; for there is plainly no limit to the possible divergence. So long, now, as any evidence of original unity is discoverable we call the languages “related dialects,” and combine them into a “family.” The term “family” simply signifies a group of languages which the evidence thus far at command, as estimated by us, leads us to regard as descended by the ordinary processes of dialectic diverication from one original tongue. That it does not imply a denial of the possibility of wider relationship is obvious from what has been said above. That there is abundant room for error in the classification represented by it is also clear, since we may take purely accidental resemblances, or the results of borrowing, for evidence of common descent, or may overlook or wrongly estimate real evidences, which more study and improved method will bring to light.

Grouping into families is nothing more than the best classification attainable at a given stage in the progress of linguistic science; it is in no small part provisional only, and is always held liable to modification, even sweeping, by the results of further research. Of some families we can follow the history by external evidences a great way back into the past; their structure is so highly developed as to be traced with confidence everywhere; and their territory is well within our reach: such we regard with the highest degree of confidence, hardly allowing for more than the possibility that some other dialect, or group, or now-accepted family even, may sometime prove its right to be added on. But these are the rare exceptions; in the great majority of cases we have only the languages as they now exist, and in more or less scanty collections, of every degree of trustworthiness; and even their first grouping is tentative and incomplete, and involves an adjournment of deeper questions to the day of more light. To complete and perfect the work of classification by relationship, or the establishment of families and their subdivisions, is the first object of the comparative study of languages. No other classification has a value in the least comparable with it; that by grade of structure is a mere recreation, leading to nothing; that by absolute worth is of no account whatever, at any rate in the present state of our knowledge. On genetic relationship, in the first place, is founded all investigation of the historical development of languages; since it is in the main the comparison of related dialects, even in the case of families having a long recorded history, and elsewhere only that, that gives us knowledge of their earlier condition and enables us to trace the lines of change. In the second place, and yet more obviously, with this classification is connected all that language has to teach as to the affinities of human races; whatever aid linguistic science renders to ethnology rests upon the proved relationships of human tongues.

That a classification of languages, to which we have now to proceed, is not equivalent to a classification of races, and why this is so, is evident enough from the principles which have been brought out by our whole discussion of the formation of languages, and which, in their bearing upon this particular point, may well be recapitulated here. No language is a race-characteristic, determined by the special endowments of a race; all languages are of the nature of institutions, parallel products of powers common to all mankind—the powers, namely, involved in the application of the fittest available means to securing the common end of communication. Hence they are indefinitely transferable, like other institutions—like religions, arts, forms of social organization, and so on—under the constraining force of circumstances. As an individual can learn any language, foreign as well as ancestral, if it be put in his way, so also a community, which in respect to such a matter is only an aggregate of individuals.

Accordingly, as individuals of very various race are often found in one community, speaking together one tongue, and utterly ignorant of any other, so there are found great communities of various descent, speaking the dialects of one common tongue, which at some period historical circumstances have imposed upon them. The conspicuous example, which comes into every one's mind when this subject is discussed, is that of the Romance countries of southern Europe, all using dialects of a language which, 2500 years ago, was itself the insignificant dialect of a small district in central Italy; but this is only the most important and striking of a whole class of similar facts. Such are the results of the contact and mixture of races and languages. If language-history were limited to growth and diverication, and race-history to spread and dispersion, it would be a comparatively easy task to trace both backward toward their origin; as the case is, the confusion is inextricable and hopeless. Mixture of race and mixture of speech are coincident and connected processes; the latter never takes place without something of the former; but the one is not at all a measure of the other, because circumstances may give to the speech of the one element of population a greatly disproportionate
preponderance. Thus, there is left in French only an insignificant trace of the Celtic dialects of the predominant race-consituent of the French people; French is the speech of the Latin conquerors of Gaul, mixed perceptibly with that of its later Frankish conquerors; it was adopted in its entirety by the Norse conquerors of a part of the land, then brought into Britain by the same Norsemen in the course of their further conquests, this time only as an element of mixture, and thence carried with English speech to America, to be the language of a still further mixed community. Almost every possible phase of language-mixture is traceable in the history of the abundant words of Latin origin used by American negroes. What events of this character took place in prehistoric time we shall never be able to tell. If any one chooses to assert the possibility that even the completely isolated dialect of the little Basque community may have been derived by the Iberian race from an intrusive minority as small as that which made the Celts of Gaul speakers of Latin, we should have to admit it as a possibility—yet without detriment to the value of the dialect as indicating the isolated race-position of its speakers. In strictness, language is never a proof of race, either in an individual or in a community; it is only a probable indication of race, in the absence of more authoritative opposing indications; it is one evidence, to be combined with others, in the approach towards a solution of the confessedly insoluble problems of human history. But we must notice, as a most important circumstance, that its degree of probability is greatest where its aid is most needed, in prehistoric periods and among uncultivated races; since it is mainly civilization that gives to language a propagative force disproportionate to the number of its speakers. On the whole, the contributions of language to ethnology are practically far greater in amount and more distinct than those derived from any other source.

The genetical classification of languages, then, is to be taken for just what it attempts to be, and no more: primarily as a classification of languages; secondarily, as a classification of radicals, as casting light, in varying manner and degree, on movements of community, which in their turn depend more or less upon movements of races. It is what the fates of men have left to represent the tongues of men—a record imperfect even to fragmentariness. Many a family once as important as some of those here set down has perhaps been wiped out of existence, or is left only in an incontinuous fragment; one and another has perhaps been extended far beyond the limits of the race that shaped it—which, we can never tell to our satisfaction.

1. Indo-European (Indo-Germanic) Family.—To this family belongs incontestably the first place, and for many reasons: the historical position of the peoples speaking its dialects, who have now long been the leaders in the world's history; the abundance and variety and merit of its literatures, ancient and modern, which, especially the modern, are wholly unapproached by those of other nations; the long period covered by its records; and, most of all, the great variety and richness of its development. These advantages make of it an illustration of the history of human speech with which no other family can bear a moment's comparison as to value, however important various other families may be in their bearing on one and another point or department of history, and however necessary the combination of the testimony of all to a solution of the problems involved in speech. These advantages have made Indo-European language the training-ground of comparative philology, and its study will always remain the leading branch of that science. Many matters of importance in its history have been brought up and used as illustrations in the preceding discussion; but as its constitution and ascertained development call for a fuller and more systematic exposition than they have found here, a special section is devoted to the subject (see Part II. beginning of Indo-European Language).

2. Semitic Family.—This family also is beyond all question the second in importance, on account of the part which its peoples (Hebrews, Phoenicians, Assyrians, Syrians, Arabs, Abyssinians, &c.) have played in history, and of the rank of its literatures. For a special treatment of it see Semitic Languages. Some of the peculiarities of the language have been alluded to above; in the monotony and rigidity of its triliteral roots, and in the extended use which it makes of internal vowel-change ("inflexion" in the special sense of that term) for the purposes of grammatical distinction, it is more peculiar and unlike all the other known families of language than these are unlike one another. There are, and perhaps will always be, those to whom the peculiarities just mentioned will seem original; but if the views of language and its history taken above are in the main true, then that opinion is untenable; Semitic language must have grown into its present forms out of beginnings accordant in kind, if not identical in substance, with those of other families; and the only question remaining to be solved is, through what processes and under what governing tendencies Semitic speech should have arrived at its present state. And with this solution is most obviously and incontestably bound up that of the other interesting and much discussed question, whether the Semitic family can be shown to be related with other families, especially with the Indo-European. To some the possession in common of grammatical gender, or of the classification of objects in general as masculine and feminine, is of itself enough to prove such relationship; but, though the fact is a striking one, and of small importance as an indication, this degree of value can by no means be attributed to it in the present state of our knowledge—any more than to any other single item of structure among the infinite variety of such, distributed among the multitude of human tongues. Many others compare the Semitic and Indo-European "roots" with one another, and believe themselves to find there numerous indications of identity of material and significance; but these also must pass for insufficient, until it shall prove possible by their aid to work out an acceptable theory of how Semitic structure should have grown out of such radical elements as those Indo-European, or structure, or out of the accordant initial products of a structural growth that afterwards diverged into two so discordant forms. To show that, both the material and the method have been hitherto wanting, and any confident decision is at least premature; but present probabilities are strongly against the solubility of the question. While many general considerations favour the ultimate unity of these two great civilized and civilizing white races of neighbouring homes, and no discordance of speech (as was shown above) can ever be made to prove their diversity of origin, it seems in a high degree unlikely that the evidence of speech will ever be made to prove them one.

3. Hamitic Family.—The prominent importance of this family (see Hamitic Languages) is due to a single one of its members, the Egyptian. It occupies the north-eastern corner of Africa, with the border-lands of that continent stretching westward along the whole shore of the Mediterranean, and southward through the desert. It falls into three principal divisions: (1) the ancient Egyptian, with its descendant, the modern Coptic (itself now for some centuries extinct; see Egypt, Copts); (2) the Libyan or Berber languages of northern Africa; (3) the Ethiopic languages of eastern Africa. Its situation thus plainly suggests the theory of its intrusion from Asia, across the isthmus of Suez, and its gradual spread from that point; and the theory is strongly favoured by the physical character of the Hamites, and the historical position, especially of the Egyptians, so strikingly different from that of the African races in general. Linguistic evidences of the relationship of Hamite with Semite have also been sought, and by many believed to be found; but the maintenance of the two families in their separateness is an indication that those evidences have not yet been accepted as satisfactory; and such is indeed the case. The Egyptian is a language of extreme simplicity of structure, almost of no structure at all. Its radical words are partly monosyllabic, partly of more than one syllable, but not in the latter case any more than in the former showing traceable signs of extension by formative processes from simpler
elements. It has no derivative apparatus by which noun-stems are made from roots; the root is the stem likewise; there is nothing that can be properly called either declension or conjugation; and the same pronominal particles or suffixes have now a subjective value, indicating use as a verb, and now a possessive, indicating use as a noun. There is no method known to linguistic science by which the relationship of such a tongue as this with the highly and peculiarly inventive Semitic can be shown, short of a thorough working out of the history of development of each family taken by itself, and a retracing in some measure of the steps by which each should have arrived at its present position from a common starting-point; and this has by no means been done. In short, the problem of the relation of Semitic with Hamitic, not less than with Indo-European, depends upon that of Semitic growth, and the two must be solved together. There are striking correspondences between the pronouns of the two families, such as, if supported by the distinction of grammatical material, would be taken as signs of relationship; but, in the absence of such support, they are not to be relied upon, not till it can be shown to be possible that two languages could grow to be so different in all other respects as are Egyptian and Hebrew, and yet retained by inheritance corresponding pronouns. And the possession of grammatical gender by Indo-European, Semitic and Hamitic speech, and by them almost alone, among all human languages, though an extremely noteworthy fact, is (as was pointed out above) in the present condition of linguistic science quite too weak a basis for a belief in the original identity of the three families.

Egyptian is limited to the delta and valley of the Nile, and is the only Hamitic language which has ancient records; of the others the existing forms alone are known.

The Libyan or Berber division of the family occupies the inhabitable part of northern Africa, so far as it has not been displaced by intrusive tongues of other connexion—in later times the Arabic, which since the Mahommedan conquest has been the cultivated tongue of the Mediterranean coast, while the earlier Vandal, Latin and Punic have disappeared, except in the traces they may have left in Berber dialectic speech. The principal dialects are the Kabyle, the Shilha and the Tuarek or Tamashek, corresponding nearly to the ancient Numidian, Mauretanian and Gaetulian respectively.

The third or Ethiopic division includes as its chief members the Beja or Bishārīn, the Soho, the Dankali, the Somali, and the more inland Galla; the first two lying along the Red Sea north of Semitic Abyssinia, the others south of it, to the equator. By some authorities (Lepsius, Bleek) there is added to the Hamitic family as a fourth division a group from extreme southern Africa, the Hottentot and Bushman languages. The ground of this classification is the possession by the Hottentot of gramatical gender, and even its indication by signs closely corresponding to those used in the Ethiopic division. Others deny the sufficiency of this evidence, and rank the Hottentot as a separate group of African dialects, adding to it provisionally the Bushman, until better knowledge of the latter shall show whether it is or is not a group by itself. If the Hottentot be Hamitic, we shall have to suppose it cut off at a very remote period from the rest of the family, and forced gradually southward, while all the time suffering mixture both of speech and of blood with the negro races, until the physical constitution of its speakers has become completely metamorphosed, and of its original speech no signs are left save those referred to above; and while such exceptional phonetic peculiarities have been worked out as the use of the clicks or clucking sounds: and this must be regarded as at least extremely difficult.

4. Monosyllabic or South-eastern Asiatic Family.—This body of languages may well enough be the next taken up; and here again (as was the case with the preceding family) on account of the prominent importance of one of its dialects and of the people speaking it—the Chinese people and language. The territory of the family includes the whole south-eastern corner of Asia: China on the north-east, Farther India in the south, and the high plateau of Tibet, with the neighbouring Himalayan regions, to the westward. The ultimate unity of all these languages rests chiefly upon the evidence of their form, as being all alike essentially monosyllabic and isolating, or destitute of formal structure; the material correspondences among them, of accordant words, are not sufficient to prove them related. The Chinese itself can be followed up, in contemporary records, to a period probably not far from 2000 B.C., and the language, the people, and their institutions, are then already in the main what they have ever since continued to be (see China); the other leading tongues come into view much later, as they receive culture and religion from China on the one hand (the Annamites), or from India on the other (the Tibetans, Burmese, Siamese); and the territory includes great numbers of wild tribes unknown until our own times, whose race-relations and language-relations are as yet very obscure. Current opinion tends to regard them with the Pegusins and Cambodians (the 'Mon-Khmer group') as forming a more nearly related group or division, and as having been the earlier population of Farther India, in part dispossessed and driven forward by the later intrusion from the north of Siamese and Burmese, of whom the former are more nearly related to the Chinese and the latter to the Tibetans. The Mon-Khmer group is itself more nearly related to the Kolarian and Malay-Polynesian.

The character of the languages of this family, especially as instanced by its most important member, the Chinese, has been pretty fully set forth in the general discussions above. They are languages of roots: that is to say, there is not demonstrable in any of their words a formative part, limiting the word, along with others similarly characterized, to a certain office or set of offices in the formation of the sentence. That the words are ultimate roots, come down from the first period of language-making, we have no reason whatever to believe; and they may possibly have passed through processes of growth by which equipped them with some scanty supply of forms; but no evidence to that effect has yet been produced. The indications relied on to show an earlier polysyllabism in the family (though already in Chinese reduced to monosyllabism before the earliest historical appearance of the language, some 4000 years ago) are the comparatively recent loss of certain final mutes in Chinese words, and the presence on a considerable scale in Tibetan spelling of added initial and final consonants, now silent in the literary dialect, but claimed to be still uttered in some parts of the country. If the theory connecting these phenomena be established, the Tibetan will approve itself to be by far the most primitive of the dialects of the family, furnishing the key to the history of the rest.

For further details respecting the various tongues of the monosyllabic family, the articles on the different divisions of its territory (Burma; China; Islam; Tibet &c.) must be consulted. The languages all alike show an addition to the resources of distinction possessed by languages in general, in the use of tones: that is to say, words of which the alphabetic elements are the same differ in meaning according as they are uttered in a higher or a lower tone, with the rising or the falling inflexion, and so on. By this means, for example, the monosyllabic elements of the literary Chinese, numbering but 500 as we should write them, are raised to the number of about 1500 words.

5. Ural-Altaic (Scythian, Turanian) Family.—China and Tibet are bordered on the north and west by the eastern branches of another immense family, which stretches through central and northern Asia into Europe, overlapping the European border in Turkey, and reaching across it in Russia and Scania to the very shore of the Atlantic. Usage has not so definitely determined as in the case of most other families by what name it shall be called; Turanian is perhaps the commonest appellation, but also the most objectionable. Five principal branches are generally reckoned as composing the family. The two easternmost are the Tungusian, with the Manchu for its principal division, and the Mongol (see Mongol)
Of these two the language is exceedingly simple in structure, being raised but little above the formlessness of the Chinese. The Tungusian, however, some authorities would couple with Japanese as a separate branch. The three others are: the Turkish or Tatar, the dialects of which reach from the mouth of the Lena (Yakut) to Turkey in Europe; the Samoyed, from the Altai down to the arctic shore of Asia, and along this to the White Sea—an unimportant congeries of barbarous tribes; and the Finno-Hungarian, including the tongues of the two cultivated peoples from which it takes its name, and also those of a great part of the population of northern and central Russia, to beyond the Ural Mountains, and finally the Lappish, of northern Scandinavia. The nearer relation of the Samoyed is with the Finno-Hungarian. The Turkish is a type of a well-developed language of purely agglutinative structure: that is, lacking that higher degree of integration which issues in internal change. Whether this degree is wholly wanting in Finnish and Hungarian is made a question; at any rate, the languages named have no reason to envy the tongues technically called "reflective." Of a value not inferior to that of instructive characteristics is one that belongs to all the Ural-Altaic tongues, in varying measure and form, and helps to bind them together into a single family—the harmonic sequence of vowels, namely, as between root and endings, or a modification of the vowels of the endings to agree with that of the root or its final syllable.

While the physical race-characteristics known as Mongolian are wanting in the speakers of the western dialects of this family, they are conspicuously present in the people of Japan and Korea; and hence the tendency of scholars to endeavour to connect the languages of the two latter countries, since they also are of agglutinative structure (see Japanese and Korean) with the family now under treatment, as also with one another. Other languages of north-eastern Asia, too little known to group, and too unimportant to treat as separate families, may be mentioned here by way of appendix to their neighbours of the most diversified and widespread Asiatic family. They are the Aino, of Yezo and the Kurile Islands with part of the neighbouring coast; the Kamchatkan; and the Yukagir and Tchuktschi of the extreme north-east. These are sometimes combined with the Eskimo under the title of the Arctic or Hyperborean languages.

The opinion has been held by many scholars that the agglutinative dialects—Sumerian, Accadian, &c.—of the presumed founders of Mesopotamian culture and teachers of the Assyrian Semites (see Babylon) belonged to the Ural-Altaic family, and specifically to its Finno-Ugrian branch; but the data for this view are still very uncertain. The mere possession of an agglutinative structure cannot be taken as proving anything in the way of relationship.

6. Dravidian or South Indian Family.—This is an important body of nearly and closely related tongues, spoken by about 50,000,000 people, doubtless representing the main population of all India at the time when the intrusive Indo-European tribes broke in from the north-west, and still filling most of the southern peninsula, the Deccan, together with part of Ceylon. They are languages of a high grade of structure, and of great power and euphony; and the principal ones have enjoyed a long cultivation, founded on that of the Sanskrit. As they obviously have no Indo-European affinities, the attempt has been made to connect them also with the Ural-Altaic or Turanian family, but altogether without success, although there is nothing in their style of structure that should make such connexion impossible.

7. Malay-Polynesian Family.—Not all the tribes that make up the non-Indo-European population of India speak Dravidian dialects. The Santals and certain other wild tribes appear to be of another lineage. These are now generally known as Kolarian, and are connected with the Malay-Polynesian family.

The islands, greater and smaller, lying off the south-eastern coast of Asia and those scattered over the Pacific, all the way from Madagascar to Easter Island, are filled with their own peculiar families of languages, standing in a more or less distant relationship to the languages of the Mon-Khmer group, and the Kolarians on the mainland and the Nicobar Islanders. The principal one among them is the great Malay-Polynesian family. It falls into two principal divisions, Malayan and Polynesian. The Malayan includes, besides the Malay proper (see Malayan), which occupies the Malaccan peninsula (yet doubtless not as original home of the division, but by immigration from the islands), the languages also of Sumatra, Java, Borneo, &c., of the Philippine Islands, of part of Formosa, and of Madagascar, together with the coasts of Celebes and other islands occupied in the interior by Papuans. The Polynesian division includes most of the tongues of the remaining scattered groups of islands, and that of New Zealand. Probably to these are to be added, as a third division, the Melanesian dialects of the Melanesian Archipelago, of which both the physical and the linguistic peculiarities would in that case be ascribed to mixture with the black Papuan races. All these languages are extremely simple in phonetic form, and of a low grade of structure, the Polynesian being in both respects the lowest, and some of the Malayan dialects having reached a development considerably more advanced. The radical elements are much oftener of two syllables than of one, and reduplication plays an important part in their extension and variation. Malay literature goes back as far as the 13th century, and there are Javan records even from the early centuries of our era, the result of religion and culture introduced into that island from Brahmanic India.

In recent years more active investigation has been carried on with a view to tracing out the special laws of historical development prevailing in the family.

8. Other Oceanic Families.—At least two other families, unconnected with the preceding and with one another, are found among the Pacific Islands, and only there. The continental island of Australia, with its dependency Tasmania (where, however, the native tongue has now become extinct), has its own family of probably related dialects, as its own physical type.

They have been but imperfectly investigated, their importance, except to the professed student of language, being nothing; but they are not destitute of a rude agglutinative structure of their own. Still less known are the Papuan or Negrito languages, belonging to the black race with frizzled hair inhabiting most of New Guinea, and found also in the interior of some of the other islands, having been driven from the coasts by superior intruders of the Malay race.

9. Caucasian Languages.—Of the existing languages of Asia there remain to be mentioned only those of the Caucasian mountains and highlands, between the Black and Caspian Seas, pressed upon the north by Slavonians and Turks, upon the south by Armenians and Kurds and Turks. Its situation makes the Caucasus a natural eddy in all movements of emigration between Asia and Europe; and its linguistic condition is as if remnants of many families otherwise extinct had been stranded and preserved there. The dialects north of the principal range—Circassian, Mitsjeghian, Lesghian, &c.—have not been proved to be related either to one another or to those of the south. Among the latter, the Georgian is much the most widespread and important (see Georgia) and, alone among them all, possesses a literature. The Caucasian dialects present many exceptional and difficult features, and are in great part of so high a grade of structure as to have been allowed the epithet "reflective" by those who attach special importance to the distinction thus expressed.

10. Remnants of Families in Europe.—The Basque people of the western Pyrenees, at the angle of the Bay of Biscay, are shown by their speech to be an isolated remnant of some race which was doubtless once much more widely spread, but has now everywhere lost its separate identity; as such it is of extreme interest to the ethnologist (see Basques). The Basque language appears to be unrelated to any other on earth. It is of a very highly agglutinative structure, being equalled in intricacy of combination only by a part of the American dialects. Limited as it is in territory, it falls into a number of well-marked dialects, so that it also may not be refused the name of a "family."

The only other case of the kind worth noting is that of the
Etruscan language of northern central Italy, which long ago became extinct, in consequence of the conquest and absorption of Etruria by Rome, but which still exists in numerous brief inscriptions (see ETRURIA). Many attempts have been made to connect the language with other families, and it has even quite recently been pronounced Aryan or Indo-European, of the Icilian branch, by scholars of high rank. But its supposed Indo-European relationship was at once shown to be erroneous when, in 1892, a small book which had been used to pack a mummy was discovered in the museum at Agram, and published. The probability of relationship with the ancient Lydian, as was the opinion held in ancient times, has been increased by recent research, and is likely soon to be verified or disproved by the discovery of Lydian records.

In order to complete the review of the languages of the Old World it only remains to notice those of Africa which have not already been mentioned. They are grouped under two heads: the languages of the south and those of the centre of the continent.

11. South African or Bantu Family.—This is a very extensive and distinctly marked family (see BANTU LANGUAGES), occupying (except the Hottentot and Bushman territory) the whole southern peninsula of the continent from some degrees north of the equator. It is held apart from all other known families of language by a single prominent characteristic—the extent to which it makes use of prefixes instead of suffixes as the apparatus of grammatical distinction; its inflexion, both declensional and conjugal, is by appended elements which precede the stem or root. The most conspicuous part of this is the variety of prefixes, different in singular and plural, by which the various classes or genders (not founded on sex; the ground of classification is generally obscure) of nouns are distinguished; these then reappear in the other members of the sentence, as adjectives and verbs and pronouns, which are determined by the noun, thus producing an alliterative concord that runs through the sentence. The nominal determinants of the verb, both subject and object, also come before it; but the determinants of mode of action, as causative, &c., are mostly suffixed. The language in general is rich in the means of formal distinction. Those dialects which border on the Hottentots have, apparently by derivation from the latter, the clicks or clucking-sounds which form a conspicuous part of the Hottentot spoken alphabet.

12. Central African Languages.—The remaining languages of Africa form a broad band across the centre of the continent, between the Bantu on the south and the Hamitic on the east and north. The Bantu group, extending from north of the equator to the southern tip of Africa, with a vast variety of dialects, is the most important of all African languages. To it belongs Swahili, the language of Zanzibar, only less valuable as a means of communication and trade than the Hausa of the Sudan, the most important of the dialects under the influence of the Hamitic languages. The African languages are by no means to be called a family, but rather a great mass of dialects, numbering by hundreds, of varying structure, as to the relations of which there is great discordance of opinion even among the most recent and competent authorities. It is no place here to enter into the vexed questions of African linguistics, or even to report the varying views upon the subject; that would require a space wholly disproportioned to the importance of African speech in the general sum of human language. There is no small variety of physical type as well as of speech in the central belt; and, partly upon the evidence of lighter tint and apparently higher culture, certain races are set off and made a separate division of; such is the Nuba-Fulah division of F. Müller, rejected by Lepsius. The latter regarded all the varieties of physical and linguistic character in the central belt as due to mixture between pure Africans of the south and Hamites of the north and east; but this is at present an hypothesis only, and a very improbable one, since it implies modes and results of mixture to which no analogies are quotable from languages whose history is known; nor does it appear at all probable that the collision of two races and types of speech should produce such an immense and diverse body of transitional types. It is far from impossible that the present prominence of the South African or Bantu family may be secondary, due to the great expansion under favouring circumstances of a race once having no more importance than belongs now to many of the Central African races, and speaking a tongue which differed from theirs only as theirs differed from one another. None of the Central African languages is a prefix-language in the same degree as the Bantu, and in many of them prefixes play no greater part than in the world's languages in general; others show special forms or traces of the prefix structure; and some have features of an extraordinary character, hardly to be paralleled elsewhere.

One group in the east (Oglah, &c.) has a gender distinction, involving that of sex, but really founded on relative power and dignity: things disparaged, including women, are put in one class; things extolled, including men, are put in the other. This is perhaps the most significant hint anywhere to be found of how a gender-distinction like that in our own Indo-European languages, which we usually regard as being essentially a distinction of sex, while in fact it only includes such, may have arisen.

Common among the African languages, as among many other families, especially the American, is a generic distinction between animate beings and inanimate things.

Literature.—Many of the theoretic points discussed above are treated by the writer with more fulness in his Language and the Study of Language (1867) and Life and Growth of Language (1875). Other English works to consult are M. Müller’s Lectures on the Science of Language; Farrar’s Chapters on Language; Wedgwood’s Origin of Language (all more or less antiquated); Sayce’s Principles of Philology and Introduction to the Science of Language, &c.; Sweet, The History of Language and Speech (Halle, 1880); Delbrück’s Einleitung in das Sprachstudium (Leipzig, 1880; 4th ed. 1900; 5th ed., 1910; there is also an English version); Brugmann and Delbrück’s Grundriss der vergleichenden Grammatik der indogermanischen Sprachen (1886–1900; a second edition of the first volume was published in 1897, two parts of vol. ii., including the stemformation and declension of the noun and pronoun appeared in 1906 and 1909); also the works of W. von Humboldt and of H. Steinthal, the most important of whose linguistic works, Charakteristik der hauptsächlichsten Typen des Sprachbaues (1861), was recast and brought up to date under the same title by F. Misteli (1893). See also handy summaries covering the same ground, but without bibliography, in F. N. Finck’s Die Sprachstemme des Erdreises (1900) and Die Haupttypen des Sprachbaus (1910). Many of the languages of India and Farther India have been treated in the Linguistic Survey of India, edited by Dr G. E. Grierson (a government publication still in progress). A short popular account of the subject is given in Porozzini’s Einleitung in die Sprachwissenschaft (1910), a German translation of a Russian original. The Bantu languages have been treated by Black, Torrard, and most recently by Meinhold, whose Lautlehre der Bantu Sprachen (1910) is the most complete handling of the subject. As to the classification and relationships of languages, see Hovelacque’s La Linguistique (Paris, 1876) and F. Müller’s Grundriss der Sprachwissenschaft (Vienna, 3 vols.; a fourth was left incomplete at the author’s
PHILOLOGY

death). Both works are already somewhat antiquated. As to the history of the study, see Lersch's Sprachphilosophie der Alten (1810); Steinthal's Geschichte der Sprachwissenschaft bei den Griechen und Römern (1861); Benfey's Geschichte der Sprachwissenschaft und Orientalischen Philologie in Deutschland (1869); Sandys's History of Classical Scholarship (3 vols., 1966-1908); Vihl. Thomsen's Sprogardenskatafen Historien Kortiattim framlning (1922).

(W.D.W.)

II.—Comparative Philology of the Indo-European Languages.

The study of Indo-European comparative philology has from its outset necessarily been in close connexion with that of Sanskrit, a language unparalleled amongst its cognates in antiquity and distinctness of structure, and consequently the natural basis of comparison in this field. It is therefore not to be wondered at that we find no clear views of the mutual relationship of the individual members of the Indo-European family or their position with regard to other languages until Sanskrit began to attract the attention of European philologists, or that the introduction of Sanskrit as an object of study was closely followed by the discovery of the original community of a vast range of languages and dialects hitherto not brought into connexion at all, or only made the objects of baseless speculations. We meet with the first clear conception of this idea of an Indo-European community of languages in the distinguished English scholar Sir William Jones, who, as early as 1786, expressed himself as follows: "The Sanskrit language, whatever may be its antiquity, is of wonderful structure; more perfect than the Greek, more copious than the Latin, and more exquisitely refined than either, yet bearing to both of them a stronger affinity, both in the roots of verbs and in the forms of grammar, than could have been produced by accident; so strong that no philologist could examine all the three without believing them to have sprung from some common source which, perhaps, no longer exists. There is a similar reason, though not quite so forcible, for supposing that both the Gothic and the Celtic, though blended with a different idiom, had the same origin with the Sanskrit."

But neither Sir William Jones nor any of his older contemporaries who had arrived at similar conclusions ever raised this important discovery from a brilliant apéndice into a valid scientific theory through a detailed and systematic comparison of the languages in question. To have achieved this is the undoubted merit of the German, Franz Bopp (q.v.), the founder of scientific Indo-European philology, and subsequently through this example also the founder of comparative philology in general. Next to him Jacob Grimm (q.v.) must be mentioned here as the father of historical grammar. The first part of his famous Deutsche Grammatik appeared in 1819, three years after Bopp had published his first epoch-making book, Ueber das Conjugationssystem der Sanskritsprache. Bopp's results were here at once utilized, yet Grimm's whole system was entirely independent of that of Bopp, and had no doubt been worked out before Grimm knew of his illustrious predecessor. In fact, their scientific aims and methods were totally different. Bopp's interest was not concentrated in comparison as such, but chiefly inclined towards the explanation of the origin of grammatical forms, and comparison to him was only a means of approaching that end.

In this more or less speculative turn of his interest Bopp showed himself the true son of a philological period when general linguistics received its characteristic stamp from the labours and endeavours of men like the two Schlegels and Wilhelm von Humboldt. Jacob Grimm's aims were of a less lofty character than those of Bopp, whose work, to his own mind, was crowned by his theory of the origin of inflexion through agglutination. In confining his task to a more limited range than the vast field of Indo-European languages embraced in Bopp's researches, and thus fixing his attention on a group of idioms exhibiting a striking regularity in their mutual relationship, both where they coincide and where they differ, he made it his foremost object to investigate and illustrate the continuous progress, subject to definite laws, by which these languages had been developed from their common source. He thus raised the hitherto neglected study of the development of sounds to an equal level with the study of grammatical forms, which had so far almost exclusively absorbed all the interest of linguistic research.

Grimm's discovery of the so-called "Lautverschiebung," or Law of the Permutation of Consonants in the Teutonic languages (which, however, had been partly found and proclaimed before Grimm by the Danish scholar Rask), became especially important as a stimulus for further investigation in this line. Grimm's influence on comparative philology (which is secondary only to that of Bopp, although he was never a comparative philologist in the sense that Bopp was, and did not confine himself to the branch of which he might have afforded him) is clearly traceable in the work of Bopp's successors, amongst whom Friedrich August Pott (1802-1887) is universally judged to hold the foremost rank. In his great work, Etymologische Forschungen auf dem Gebiete der indogermanischen Sprachen, mit besonderem Bezug auf die Lautumwandlung im Sanskrit, Griechischen, Lateinischen, Italienischen, und Gotischen (Lemgo, 1833-1836), we find Indo-European etymology for the first time based on a scientific investigation of general Indo-European phonology. Amongst Pott's contemporaries Theodor Benfey deserves mention on account of his Griechisches Wurdellexicon (Berlin, 1839), a work equally remarkable for copiousness of contents and power of combination, yet showing no advance on Bopp's standpoint in its conception of phonetic changes.

A third period in the history of Indo-European philology is marked by the name of Schleicher, whose Compendium der vergleichenden Grammatik der indogermanischen Sprachen first appeared in 1861. In the period subsequent to the appearance of Pott's Etymologische Forschungen, a number of distinguished scholars, too large to be recorded here individually, had devoted their labours to the different branches of Indo-European philology, especially assisted and promoted in their work by the rapidly progressing Vedic (and Avestic) studies that had been inaugurated by Rosen, Roth, Benfey, Westergaard, Müller, Kuhn, Aufrecht and others. Moreover, new foundations had been laid for the study of the Slavonic languages by Miklosich and Schleicher, of Lithuanian by Kurschat and Schleicher, of Celtic by Zeus. Of the classical languages Greek had found a most distinguished representative in Curtius, while Corses, Mommsen, Aufrecht, Kirchhoff, &c., had collected most valuable materials towards

Bopp and J. Grimm.

For this quotation and the following historical sketch in general see Th. Benfey, Geschichte der Sprachwissenschaft, p. 438 (Munich, 1865), and especially B. Delbrück, Introduktion to the Study of Language, p. 1 (Leipzig, 1882; a fifth German edition appeared in 1909).

3 The extensive progress made in this period is best illustrated by the foundation of two periodicals especially devoted to Indo-European comparative philology, Kuhn's Zeitschrift für vergleichende Sprachforschung (now 27 vols., Berlin, from 1851), and Kuhn's Beiträge zur vergleichenden Sprachforschung (8 vols., Berlin, from 1898). Benfey's school is more especially represented by the contributions of his pupils. Bopp's school is represented in Zeitschrift für philologische Wissenschaft (Berlin, from 1862), and subsequently through Beesenberger's Beiträge zur Kunde der indogermanischen Sprachen (30 vols., Göttingen, from 1877); this journal has now been amalgamated with Kuhn's Zeitschrift. The third school, that of Grimm and Bopp's pupil, Brugmann, Osthoff and their schools—are represented in Indogermanische Forschungen (27 vols., since 1890). The Göttingen school has a further representative in Glotta, now (1910) in its third volume. The history of the meaning of words has a special periodical for itself, Wörter und Sachen, now in its second volume. Besides those mentioned there are many journals, Publications of academies, &c., in Belgium, Sweden, Denmark, Italy, &c., which have a serious student (in general of philology), and there are periodicals of the same kind, the Revue de Linguistique (Paris, from 1868) and the Mémoires de la Société de Linguistique de Paris (also from 1868), while England is represented by the Proceedings and Transactions of the Philological Societies of London and Cambridge, the Classical Review (23 vols., since 1887), and the Classical Quarterly (4 vols., since 1907), and America by the Transactions of the American Philological Association (from 1868), the American Journal of Philology (30 vols., from 1866), Classical Philology (5 vols., from 1906), and other more specialist organs.
the elucidation of Latin and the cognate Italic idiom. In his Compendium Schleicher undertook and solved the difficult task of sifting down the countless details amassed since the days of Bopp and Grimm, and thus making the individual languages stand out clearly on their common background, while Bopp's attention had been especially occupied with what was common to all Indo-European tongues. There are two prominent features which characterize this part of Schleicher's work—his assumption and partial reconstruction of a prehistoric parent speech, from which the separate Indo-European languages were supposed to have sprung, and the establishment of a long series of phonetic laws, regulating the changes by which that development of the individual idioms had taken place. On Schleicher's views of and contributions towards general comparative philology (which he erroneously proposed to consider as a branch of natural science) we need not enter here. (See Evolution and the Science of Language in Darwin and Modern Science, 1909, pp. 526 sqq.)

For some time after Schleicher's premature death (in 1868) Indo-European philology continued in paths indicated by him and pursued, with the exception, perhaps, of the school founded by Benfey, who had always stood on independent ground. The difference between the two schools, however, was less strikingly marked in their writings, because it chiefly concerns general views of language and the Indo-European languages in particular, although the characteristic task of the period alluded to was that of working out the more minute details of comparison; but behind all this the general interest still clung to Bopp's old glottogonic problems. In 1876, however, a new movement, inspired in the first instance by the works of W. D. Whitney, began, and a younger school of linguists has sprung up who are united in their opposition to many theories of the older generation, yet often differ materially both with regard to method and the solution of individual problems. In its present state this younger school (often branded with the name of Neo-Grammarians, "Junggrammatiker," by its opponents real and imaginary) is marked by certain distinct tendencies. In the first place, they are inclined more or less, and the older members of the school perhaps more than the younger, to abandon glottogonic problems as insoluble, if not for ever, yet for the present and with the scanty means that Indo-European philology alone can furnish for this purpose. In this they are in opposition to the whole of the older school. In the second place, they object to the use of all misleading metaphorical comparisons of processes in the history of language with processes of organic development—comparisons used at all times, but especially cherished by Schleicher. In the third place—and this has been of the greatest practical importance—they hold that our general views of language and our methods of comparison should be formed after a careful study of the living languages, because these alone are fully controllable in every minute detail, and can therefore alone give us a clear insight into the working of the different motive forces which shape and modify language, and that the study of language, as a whole, cannot be adequately pursued once more for the formulation of the question whether phonetic laws actually exist. It must be admitted in the first place that the word law has been ill chosen for use in this connexion. In phonetic laws there is no element which can be identified as coming under the definition of a law as propounded by a jurispru director like John Austin. There is no authority which enunciates the law, there is no penalty for the breach of it. But the philologists who first used the term were not thinking of law in its strict signification, but of its use in such metaphorical expressions as scientific laws, for, as already mentioned, Schleicher and his followers in the middle of the 19th century had taken a keen interest in the development of the natural sciences, and had to some extent assimilated their terminology to that employed in those sciences. It was, however, soon recognized that the laws of language and those of natural science were not really alike or akin. A scientific "law" is only a brief method of expressing the fact that universal experience shows that certain causes universally produce certain effects. In chemistry two atoms of
hydrogen and one of oxygen will make water, and they will make nothing else at any time or at any place the world over. Phonetic laws, however, do not hold true universally. They are often curiously limited in the area to which they apply. In ancient Greek, for example, the sound -s- between two vowels, which had been handed down from the original language whence Greek and the sister languages are derived, regularly disappears; in Latin, on the other hand, it changes into -r-; thus an original genitive of a neuter substantive we find represented in Greek by γένος, a form which comparison with other languages shows to be traceable to an earlier *genes-os, preceding the separation of the languages, while the same original stem with a different vowel in the ending appears in Latin as gener-is. Similarly an early *euto appears in Greek as ἐξο, in Latin as utro. This disappearance of original intervocalic s pervades all Greek dialects—the apparent exceptions come under the heading of analogical change; with a very few exceptions similarly explicable Latin intervocalic s has become r. But Latin was originally limited to a very small part even of Italy, and the next neighbours of the Latins on the east and south—the Sabines, Campanians and Samnites—retained this intervocalic s without changing it into r. On the other hand, the neighbours to the north-east—the Umbrians in and beyond the Apennines—shared in this rhotacism. Yet the Celts, who bordered on the Umbrians along the Po, and who spoke a language in many respects very closely akin to the dialects of Italy, in this regard agree rather with Greek than with the Italic languages. In Latin, again, the period of action of the law which changed intervocalic s into r did not in all probability exceed the century from 450 B.C. to 350 B.C. So unlike, indeed, are phonetic laws to the laws of natural science in universality that an opponent of the dogmas which declares that phonetic laws have no exceptions has compared them with the laws of fashion. The comparison is not so outrageous as it may seem at first sight. For in language there are two kinds of sound change, that which is unconscious, universal at a given time and within a given area, and, on the other hand, that which belongs only to a particular class or clique, deviates consciously from the pronunciation of the majority, is therefore not universal, and exercises no permanent influence on the language. The second kind of sound change corresponds exactly to the laws of fashion; it is in fact one of them. Such sound changes are the pronunciation of the English ending -ing as -in', which was fashionable in the middle of the 10th century. This had, though probably without the knowledge of those who used it, an historical justification in the earlier forms from which most of the English words now ending in -ing are descended, and which survive in numerous local dialects. A similar conventional mispronunciation was the lisp affected by young women; it disappeared in a somewhat later period. Belonging to an entirely different social stratum, and now equally obsolete, was the London pronunciation of the first half of the 19th century characterised in Tony and Sam Weller's treatment of s and w in the Pickwick Papers. This, however, made a much nearer approach to being a genuine dialect peculiarity. It undoubtedly pervaded the pronunciation of the lower classes in London at one time; had it survived it might conceivably have spread over a wider and wider area until it embraced the whole population of England. A later change, that of the diphthong ai into ei (so that day, daily are pronounced dy, dyly), has spread from Essex and the East End of London over a large part of London and of the adjacent counties, and is still widening its range both geographically and socially. The history of these sound changes has not yet been investigated in detail with the thoroughness with which it has been treated for Latin. There is, then, a part of sound change which is a matter of fashion and which is conscious. This sound change appears frequently in the pronunciation of individuals who have migrated from one part of a country to another. In many parts of Scotland, for example, the prepositions with and of appear in dialect only in the forms wi and of', which were originally the unaccented forms. In the conscious attempts to pronounce them as they appear in literary English, the educated Scotsman, if he remains in his native place, as a rule pronounces them as with (with the final sound unvoiced as it appears in the Scottish legal preposition *outwith) and as of, the final sound here also being unvoiced. If he migrates to England or to Australia he will probably in course of time adopt the pronunciation with a voiced final sound. In the course of years habit will become second nature, and in this respect the speaker's pronunciation will become identical with that of his neighbours. It is clear, however, that changes of this nature cannot take place on a large scale. If a large number of persons migrate in a body and continue to live in close intercourse with one another and but little in contact with the outside world, changes such as take place in the pronunciation of the individual emigrant do not occur. There can be no imitation of alien sounds, for there are none; no greater effort to be intelligible is required, for the audience has not changed. Hence it has been often remarked that a population which history shows to have remained undisturbed for very long periods in the same geographical situation manifests but little change in its language. Thus in Arabia and Lithuania the population has remained practically unmixed in the same habitat for thousands of years, with the result that the languages spoken there remain at the present day the most archaic members of the linguistic families to which they respectively belong.

From what has been said it will be obvious that a phonetic law is only an observed uniformity in the treatment of a sound or a combination of sounds within a linguistic area at a given time. In the definition the term linguistic area is a very variable quantity. Thus it is a phonetic law that a sound of the original Indo-European language, the precise pronunciation of which cannot be determined, but which was at any rate a palatal sound (k), appears in the Indo-European group (Sanskrit, Zend, Old Persian, with its descendants), in Armenian, in Balto-Slavonic and Albanian. In the form of a sibilant, while in Greek, the Italic dialects, Germanic and Celtic, it appears as a k-sound (see Indo-European Languages). Here the linguistic area is extremely wide, and it is clear that the difference between the two groups of languages must be dated back to a very early period. Again, it is a phonetic law of Greek that the original combination st- at the beginning of words is retained in Greek. How then are we to explain the existence side by side of στίγος and τρίγος? The former apparently complies with the law, the latter does not. The former has by its side the verb οτρύγο, while τρίγος is supported only by the rare τρηγ. Yet the forms of the verb and substantive found in the Germanic languages leave no doubt that the forms without s- represent an extremely old form, for the English batich could not have changed its original t- into th- if it had been preceded by s-, the law being as strict for English as for Greek that st- remains unchanged. On the other hand, a phonetic law may be limited to a very small area. Thus in the dialect of Eretria, and nowhere else within the area of the Ionic dialect of ancient Greek, do we find the change of the sound which appears elsewhere in Greek as a- between vowels into -e: στίγον for στίγον (acc. sing.), παραβαίνων for παραβαίνων (3rd pl. subjunctive). This change should take place here and nowhere else we do not know, although it may be conjectured that the cause was a mixture with immigrants speaking a different dialect, a mixture which ancient tradition supported. Undoubtedly such mixtures are the chief conditions of phonetic change, the effect of which is universal. The manner in which the change takes place is that the basis of articulation, the method in which the sound is produced, becomes changed. Thus along the "Highland line" in Scotland, where the English and Gaelic-speaking populations have the linguistic frontier for centuries, the English, the English, the Highlanders, the Gaelic, the Irish, the Scots, the English, become universally ld, who? becoming lo? white, file, &c., being the sound which it was easiest to substitute for the difficult lw-. The history of Spanish in the different communities of South America excellently illustrates this point. After the discovery of America there was a large influx of Spaniards into Chile, who ultimately, and chiefly by intermarriage, incorporated amongst them a considerable element from amongst the native Araucanian Indians. The result has been...
that the language of Chile is Spanish, pronounced not with the
genuine sounds of Spanish, but with the sounds of the Araucanian
language substituted for them. Elsewhere in Spanish America
the language of the conquerors remained comparatively pure,
because the Spaniards were much fewer in number, and had
therefore to maintain themselves as a caste apart. For the same
reason Latin has split up into the numerous branches which we
know as the Romance languages. The particular line of
development which, e.g. French followed as compared with
Spanish or with the language of the Rhaetian Alps was condi-
tioned by the nature of the sounds in the language which pre-
ceded it in that same area, and which was spoken by the ancient
Gauls who adopted Latin. The difficulty found in all of these
cases is precisely of the same kind as that which an adult at
the present day speaking one language finds in attempting to learn
the pronunciation of another language. On the one hand, it is
only with the greatest difficulty that muscles for many years
acquainted to perform one set of movements can be forced into
performing another set which are very similar but yet not
identical; on the other hand, to an untrained ear the difference
between the two sounds may remain unappreciated. The result
is that the new language is pronounced with the sounds of the
speaker’s original language. If the new language is adopted by
a whole people to whom it was originally foreign, the children
naturally learn it from their parents with the sounds of the old
language which has now become obsolete. Thus the basis of
articulation is changed, and if, as was the case with Latin, this
process be frequently repeated among peoples speaking languages
with articulation widely differing one from another, it is clear
that a series of different dialects of the adopted language has
been created. This kind of change is immediate and universal
throughout the whole area where linguistic change has taken
place.

Analogical change, on the other hand, does not affect the
pronunciation of a language as a whole in the way that phonetic
change does, but is confined to the formation, inflexion, syntax
and meaning of single words or groups of words, and therefore is
very apt to bear an entirely arbitrary and irregular character.
A few instances will be sufficient to illustrate this and also to
show how the apparently irregular phenomena of analogy may be
classified. (a) In Old English a certain number of substantives
formed their plurals by mutation of the root vowels, as fót, fét, or
bóc, béc. In Modern English this system of inflexion has been
preserved in some cases, as in foot, feet, and altered in others, as
book, books. Now, while foot, feet and book are the regular
modern phonetic equivalents of the old fót, fét, bóc, the plural
books can in no way be phonetically traced back to the old bóc;
the phonetical equivalent of which in Modern English would be
*böoch. The only possible explanation of a form like books is
that the older bóc was at some date given up and replaced by an
entirely new formation, shaped after the analogy of the numerous
words with a plural in -s without modification of the root-vowel.
Such changes, which are very numerous, exemplify the first kind
of analogy, which is generally termed formal analogy. Other
examples are the almost entire disappearance from the language
of the forms in er and en, which were earlier used as plurals in
English. That they were originally stem and not case suffixes
does not affect the point. In Middle English, as in Modern
English, exen was spelt as a plural; exen survives, but iyen, except
in such dialect forms as the Scotch e’en, has been replaced by the
form in -s: eyes. Similarly in Middle English the suffix -er ex-
cisted in many words which had been originally of the neuter
case, but which have now become masculine, as in the genitive
traces of, which besides the survival in dialect of childe and of
calver (become by the 16th century in northern Scotch căr—
pronounced as căr—which is still in common use), are to be
found in the place, and hence personal, names Childer-ley and
Calver-ley. The old plural of brother was brither, where the
suffix, however, contained an original -r, not -s changed into -r,
as did childe and calver. In Old English, alongside the form for
child making a plural childe, there had been a masculine form
making its plural in -s. It would not have been surprising there-

fore if in Modern English the plural of child had been childe. But
in spite of the common tendency to make the plural of all nouns
in -s, child has gone in the opposite direction and has not
only maintained its -r, but has added to it the -en of stems like
oxen and eyen. In Wiclif we find a similar plural to call, calveren,
but here calves has long replaced in the literary language both
the earlier forms.

(b) Let us now take another instance from the English verb.
In Old English the different persons of the preterite indicative
in the so-called strong (irregular) verbs were generally distin-
guished by different root-vowels; ridan, “to ride,” and bindan,
“to bind,” for instance, form their preteritess thus: ic rād, ðu
ride, hē rād, we, gē, hē ridon, and ic band, ðu bande, hē baned, we,
ge, hē bīdon. In modern English this difference in the root-
vowels has been abandoned, and rode, bound now stand for all
persons, rode being the modern phonetic equivalent of the 1st
and 3rd sing. rād, while bound represents the u-form of bindan.
When one form or set of forms ousted other varying forms from
the same paradigm, the change is described variously as
material or logical analogy. Inasmuch as a similar process of
levelling to that seen in rode has been carried through in all
preterites of Modern English, regularity prevails even here, though
a few traces of the old conflict are still visible in such poetic
forms as sung for the preterite side by side with sung. But
when we look to its results in the individual verbs we soon find
that the choice amongst the different forms which might have
served as starting-points has been entirely arbitrary. It is
impossible to say why the old singular form should have
been chosen as a model in one case, as in rode, and the old plural
form in another, as in bound. From these and numerous similar
instances we must draw the conclusion that it is beyond our
power to ascertain whence analogical changes start, and to
what extent they may be carried through when once begun.
All we can do is to classify carefully the single cases that come
under our observation, and in this way to investigate where
such changes are especially apt to take place and what is their
general direction. As to the latter points, it has been observed
before that levelling of existing differences is one of the chief
features in analogical change (as in the case of rode and bound).
As to the former, it must be borne in mind that, before any ana-
logical change can take place, some mental connexion must exist
between the words or forms serving as models and those which
are remodelled after the types suggested to the minds of the
speakers through the former. Of such natural mental combina-
tions two classes deserve special notice: the mutual relationship
in which the different, say inflexional, forms of the same word
stand to each other, and the more abstract analogies between
the inflexional system of word-groups bearing a similar character
as, for instance, the different declensions of nouns and pronouns,
or the different conjugations of verbs. The instance of rode,
bound may serve to illustrate the former category, that of books
the latter. In the first case a levelling has taken place between
the different forms of the root-vowels once exhibited in the
different preterite forms of ridan or bindan, which clearly
constitute a natural group or mental unity in consequence of
their meaning. The form of rode as a plural has simply been
taken from the old singular rād, the long a of which has become
in Modern English ə, that of bound as a singular from the old
plural bundon, the u-sound of which in Modern English come
to be pronounced as a diphthong. In the case of book, books
for bóc, béc, this explanation would fall short. Although we
might say that the vowel of the singular here was carried into the plural,
the inflexional system of word-groups possesses no apriori
indication that the old declension of bóc, béc was remodelled after the
decension of words like arm, arms, which had always formed
their plurals in -s. The changes indicated may generally be
shown by a proportion, the new analogical formation being the
unknown quantity to be ascertained. Thus in the case cited
above, arm: arms = book: x; and clearly the form to be
ascertained is books. Isolated words or forms which are no
part of natural groups or systems, inflexional, formative or syn-
tactical must be regarded as commonly safe from alterations

PHILOLOGY 433
PHILOLOGY

through analogy, and are therefore of especial value with regard to establishing rules of purely phonetic development.

(c) In syntactical analogy the mental connexion between the two series of constructions between which the change takes place is generally still more conspicuous. The connexion may be one of similar or of contrasted meaning. In Latin, adjectives of fullness, like other adjectives, no doubt originally were followed by the genitive case; participles, on the other hand, were followed by the instrumental ablative. Thus Plautus in the Aulularia 813 and elsewhere could say "aulam suri plenam," "a pot full of gold," or "saurum onustam auro," "a pot laden with gold." From these the transition was easy to the construction "aulam onustam suri," as if in English one should say (as was possible in Earlier English), "a pot laden of gold." In English, contrasted words often tend to assimilate their syntactical constructions. Thus, the adjectives like and similar are followed by the preposition to (though in Modern English like need have no preposition), and upon the analogy of such words, different and opposite, with which correct speakers and writers couple from, are by no means rarely followed by to. Nor is it uncommon to hear or to have differ instead of differ from, upon the analogy of agree with.

Curiously enough, Latin, from which differ is descended, is found to follow the same analogy even in good writers. Thus Cicero (Academica Pr. ii. 143) combines dissidere with cum, as later does Seneca (Epistulae, 18. i):

(d) In the development of analogy in meaning, similarity of sound is often the effective cause. Thus importunt is properly irrelevant, not to the point; and is still so used in legal language; its more common signification of "saucy" arises from its accidental resemblance in sound to poet, a word which curiously enough has reversed its meaning, being now used in the sense of mal-apert, while the Old French apert, aspert (a confusion of Lat. apertus, "open," with expertus, "skilled"), meant both "open" and "skillful." Thus from very early times the verbs fly and flee have been confused, though they are of entirely different origins. When Middle English began to lose its verb endings in -en, it was very easy for the verb leren, "teach," and lernen, "learn," to be confused. Hence frequently in Elizabethan English learn stands side by side with teach in the same signification. Cf. Tottell's Miscellany, p. 129 (Arber):

"I would not have it thought thereby
The dolphin swinme I meante to teache;
Nor yet to learn the Fawcon flie;
I rowe not so farre past my reache."

It is true that the distinction between phonetic and analogical change has always been acknowledged in comparative philology. At the same time it cannot be denied that analogical changes were for a long time treated with a certain disdain and contempt, as deviations from the only course of development then allowed to be truly "organic" and natural, namely, that of gradual phonetic change (hence the epithet "false" so constantly attached to analogy in former times). Amongst those who have recently contributed most towards a more correct evaluation of analogy as a motive power in language, Professor Whitney must be mentioned. In his place of Professor Scherer (Zur Geschichte der deutschen Sprache, 1868) was the first to apply analogy as a principle of explanation on a larger scale, but in a wilful and unsystematic way. Hence he failed to produce an immediate and lasting impression, and the merit of having introduced into the practice of modern comparative philology a strictly systematic consideration of both phonetic and analogical changes as co-ordinate factors in the development of language rests with Professor Leskien of Leipzig, and a number of younger scholars who had more or less experienced his personal influence. Amongst these Brugmann, Osthoff and Paul rank foremost as the most vigorous and successful defenders of the new method, the correctness of which has since been practically acknowledged by most of the leading philologists of all shades of opinion.

While the syntax of individual languages was one of the first features which attracted the grammarians' attention, at any rate in so far as particular authors differed from a given standard, it is only in very recent times that syntax has received methodical treatment from the comparative point of view. It may indeed be said that almost the whole fabric of the comparative syntax of the Indo-European languages as it exists to-day has been reared by one man—Professor Berthold Delbrück of Jena. In a series of brilliant studies beginning with a pamphlet on the Locative, Ablative, and Instrumental, published in 1867, and continued in his Syntactical Researches (Syntaktische Forschungen) in five volumes, comprising a treatment of the conjunctive and optative moods in Sanskrit and Greek (1871), the theory of the Sanskrit tenses (1877), the order of words in early Sanskrit prose (Cātapatra Brahman, 1878), the foundations of Greek syntax (1879), and the syntax of the oldest Sanskrit (Aitantische Syntax), dealing exclusively with the literature of the Vedas and Brahmanas (1888), Professor Delbrück laid the foundations for his treatment of comparative syntax in three volumes (1883, 1887, 1900), which has formed the completion of Brugmann's Grundriss der vergleichenden Grammatik der indogermanischen Sprachen. The only work on another hand (on a large department of the subject) which deserves to be mentioned by the side of Delbrück's studies is the small treatise by Hübschmann on the theory of the cases (Zur Kasuslehre, 1879). For the comparative neglect of this field of investigation there are several reasons. The earlier philologists had so much to do in determining the languages which should be included within the Indo-European group, and in organizing the field of research as a whole, that it is not to be wondered at if they were unable to devote much attention to syntax. In the seventies, when attention began to be more directed towards comparative syntax, the remarkable discoveries made by Verner with regard to accentuation, and by Brugmann, Collitz and others with regard to the phonology of the Indo-European languages, again distracted attention from the subject. Moreover, the research in itself is infinitely more difficult than that into sounds and forms; for the latter may be carried on by the help of grammars and dictionaries with a comparatively small knowledge of the literature of any individual language, while on the other hand the study of syntax is impossible without a thorough and intimate knowledge of the literature and modes of expression in each separate language. It is not, therefore, matter for wonder that Delbrück has confined himself in the investigation of syntax to a part only of the languages whose sounds and forms are discussed by Brugmann in the earlier volumes of the Grundriss. To cover the whole ground is beyond the powers of a single man, and there is a great lack of preliminary studies on the syntax of many of the languages.

One of the most difficult problems connected with syntax, but primarily, as it appears, a question of morphology, is the origin of grammatical gender. It cannot be said to be an advantage to the languages which possess it, while languages which, like English, have dropped it except for an occasional metaphor, suffer no loss. Nor is the problem confined to the history of one language; for the whole question of the substantives. Even more perplexing is the introduction of gender into the adjective. The pronouns of the first and second persons, which are certainly very old, show no trace of gender; the pronouns of the third person, which are more of the nature of deictic adjectives, generally possess it. To the question how grammatical gender arose in the substantive, the answer was till comparatively recently supposed to be that primitive man was given greatly to personification, endowing inanimate things with life and attributing to them influences benign or the reverse upon his own existence. The answer is not quite sufficient, for though this tendency to personification, which philologists have perhaps unduly decried or altogether denied, might account for life being attributed to inanimate objects, it hardly explains why some should be treated as masculine and others as feminine. Nor is it true, as has also been suggested, that in the case of the lower animals the generic name for the larger and stronger animals is masculine and that for the smaller or weaker feminine. In both Greek and Latin the wo...
is masculine and the fox feminine, but the lamb or the chicken which the fox robs from the fold or the hen roost is rarely feminine, generally masculine. Nor does this explanation account for the mouse in those languages being of the masculine gender, while the ferret or cat which caught them is feminine (γατά, feles). An explanation which completes the theory of personification, if it does not altogether drive it from the field, has been put forward by Brugmann. 1 In its briefest form this explanation is that gender was attached to certain suffixes because they chanced to occur frequently in words which markedly implied sex. In the Indo-European languages the commonest suffix indicating feminine gender is *ā. According to this theory it had originally nothing to do with gender, but as some early words for woman or wife ended with this sound it came to be identified with feminine gender. Similarly the ending *s in o-stems occurred often in names connected with males and so became identified with the masculine gender. But many stems indicate either gender indifferently, and even the very old sex words *father and *mother have the same ending. But when masculine and feminine endings have been attached to certain suffixes in this way, how comes it that in one series of stems the neuter should be marked not by an absence of all suffix but by a separate suffix in -m? These are the o-stems, other forms of which have been markedly identified with the masculine gender. As this characteristic, like the others mentioned, goes back apparently to a time before the separation of the Indo-European languages, explanation can hardly pass beyond speculation. It is, however, to be noted that the neuter form of the nominative is phonetically identical with the accusative form of the masculine, and it has been ingeniously argued 2 that such forms were used originally in the accusative, such neutrals not forming the subject to a verb. To the same writer the most plausible explanation of the presence of gender in the adjective is due, viz., that gender began with the deictic pronoun *so “that man,” *sā “that woman,” and that hence it passed to the adjective with which the pronoun was so frequently accompanied. If this explanation be right, analogy has brought into the Indo-European languages the useless multiplication of gender marks in such sentences as the Latin hae pulcræ feminae caecæ sunt, where the feminine gender is indicated no less than four times without any obvious gain over the English These fair women were slain, where grammatical gender is no longer obviously indicated at all.

Closely related to this question is that of the history of the neuter plural, which was first fully worked out by Professor Johannes Schmidt of Berlin. 3 The curious construction, such as *Helenus and *Cyrus, whereby a neuter plural thence joined with a singular verb, is now demonstrated to be an archaic survival from the time when the neuter plural was a collective singular. Thus a word like the Latin inugum was a single yoke, the plural inūga, however, which was earlier inūgā, was a collection of yokes, with the same final *ā as is found generally in feminine substantives. The declension ought therefore to have been originally: nominative inūga, genitive inūgās, &c., like mensa, &c., of the first declension. But as inugum was used in the neuter singular for both nominative and accusative, inūgā when it was felt as the corresponding plural was used for the accusative as well as the nominative, while the other cases of the plural were taken over from the masculine o-stems, with which the singular neuter in *-m was so closely connected. That collective words should be used for the plural is not surprising; the English youth, first an abstract, next a collective, and finally an individual, is a case in point.

For the early history of the syntax of the verb Greek and Sanskrit are important above all other languages, because in them the original forms and the original usages are better preserved than they are elsewhere. And it is in the verb that the great difficulties of comparative syntax present themselves. The noun system is so well preserved in several languages that, when the number of the original cases had once been determined, the siting of the pro-ethic usages attaching to each case was tolerably easy, for besides Sanskrit and (to a less extent) Latin, Lithuanian and Slavonic have kept the pro-ethic case system almost complete. The ideas also which had to be expressed by the cases were on the whole of a very concrete character, so that here the problem was much simplified. On the other hand, the ideas expressed by the forms of the verb are of a much more subtle nature, while the verb system in all languages except Greek and Sanskrit has broken down earlier and more completely than the noun. It is clear that the verb of the original Indo-European language possessed two voices, and forms corresponding to what we call the Indicative, Subjunctive, and Optative moods, and to the Present, Imperfect, Future, Aorist, and Perfect tenses. The imperative mood seems primitively to have been confined to the second person singular, just as the vocative, which, like the imperative is a stem form without suffix, was confined to the singular. The infinitive, as is well known, is in all languages of this system not originally a verbal but a substantive form. The pluperfect, where it has developed, seems to be a mixed form arising from the application of aorist endings to a perfect stem. Thus far the history of the verb system is tolerably clear. But when we attempt to define the original meaning of the moods and of the tenses we pass into a region where, in spite of assiduous investigation in many quarters during recent years, the scanty amount of light thrown on the problem has only served to make the darkness visible. As regards the tenses, at least, it has been shown that without doubt there is no difference in formation between present, future and aorist stems, while the earliest meaning of the perfect was that of a specific kind of present expressing either repeated or intensive action or a state. It has also been proved that the original meaning of the aorist is not past time, and that in fact the only element whereby these languages could express remoteness in time was the augment. The augment seems to have been originally a pronominal deictic particle. Thus, as there was no original pluperfect, and as the perfect was by aorist originally referred to past time, and as the future, except in Lithuanian (with slight traces in Slavonic) and the Indo-Iranian group, cannot be clearly distinguished from the aorist, the system as a method of expressing time absolutely breaks down. The tenses in fact did not originally express the times when the action took place, but the type of action which took place. Thus the present system in the main expressed continued or durative action, the aorist action and state, the future action or state.

The action indicated by the aorist might have been of considerable duration, or it might have been begun and ended in a moment; its characteristics in this respect are not in any way indicated by the aorist form, which intimates only that the action is viewed as a completed whole and not as a continuous process. The present system, however, is built up in a great variety of ways (thirty-two according to Brugmann's enumeration). It is a priori unlikely that such a multiplicity of formations had not originally some reason for its existence, and Delbrück thinks that he has discovered a difference in syntactical value between various forms. The reduplicated present forms of the type seen in Sanskrit jīgatī, Greek βίβαμ, &c., he regards as expressing originally an action which consisted of repeated acts of the same nature (iterative), though this iterative meaning frequently passed into an intensive meaning. Presents of the type seen in Sanskrit te ṣabdāti, *“ is thirsty,” and Greek χάπαρνο, “am glad” (for *χαπαρνο), where the *y of the suffix has modified the final syllable and disappeared, he regards as cursive—i.e., they express continuous action without reference to its beginning or end. Verbs which have regard to the beginning or end of the action he calls terminative, and finds them represented (a) in verbs with *n-suffixes, Sanskrit ḍāyati, ḍuṣati, “sets in motion,” ḍaṃya, “break to pieces”; (b) in verbs with the suffix *sko-, Sanskrit gāchati, “goes” (to a definite destination), Greek βάλω, &c. The roots he classifies as momentary (punctuellar) or non-momentary, according as they do or do not express an action which is begun and ended at once.

---

3. Pluralbildungen der indogermanischen Neutra (1869).

This method of classification was no doubt suggested in the first instance by the characteristics of the Slavonic verb system. In this system a clear distinction is drawn in nearly all verbs between those which express a process (deixis) and those which express a completed action (perfective verbs). When perfective and durative verbs are formed from the same root, the perfective are distinguished from the durative forms (a) by having a preposition prefixed, or (b) by having a different stem formation. Thus in the Old Bulgarian (Old Ecclesiastical Slavonic) tostrike (hit) and to strike dead are expressed by the same verb, but in the latter meaning a preposition is found which does not appear in the former. biti (infinitive), "to strike"; u-biti, "to strike dead." To strike is durative; to strike dead is perfective. As an example of difference of stem formation expressing this difference of meaning, we may quote séstì, "to sit down" (perfective), séděti, "to sit" (durative). Verbs with a suffix in -n- have often a perfective meaning; cf. the Sanskrit and Greek verbs quoted above. The perfective verbs correspond in meaning to the Greek aorist, and are to be carefully distinguished from perfect forms. The same distinction of meaning is often achieved in other languages also by means of prepositions, e.g. in Latin (Seneca, Epk. x.iii. 10), Quid autem ad rem pertinet, quamdquè vites, quod evitare non possis? What does it matter how long you go on avoiding [durative] what you cannot escape [perfective]. From this example, however, it is clear that, though the means employed to make the distinction are different, there is no difference in meaning between such perfective verbs and those classified by Delbrück as terminative. Here, as in many other parts of this study, the ideas are new, and grammatical terminology has not yet sufficiently crystallized, and still leaves something to be desired both in clearness and in precision.

As regards the moods, the difficulty has been to find any criterion whereby the functions of one mood should be differentiated from those of the others. It has long been recognized that the difference between indicative and subjunctive is one of meaning and not one of formation; that, e.g., in Sanskrit bharatì (3rd sing. pres. indic.), "hears," is morphologically identical with hanati, "may slay" (3rd sing. pres. subj.), and that the latter is described as a subjunctive only because of the meaning, and because there exists a disyllabic form, kasti, which makes the indicative "slays." Similarly in Greek it is impossible to distinguish morphologically between παλω, "I shall check" (fut. indic.) and παλεω, "let me check" (1st aor. subj.). Moreover, in the earliest forms of the languages which preserve the moods best (Greek and Sanskrit), the connexion syntactically between the indicative and the subjunctive forms is closest. Thus modern Indo-European languages, particularly the Teutonic, have retained an independent subjunctive mood, the determination of the subject to carry out the action expressed, which, in Delbrück's discussion of the moods, is precisely the point chosen as characteristic of the subjunctive. On the other hand, the present optative differs from the present (and future) indicative and present subjunctive in having a special mood suffix, and in having secondary while they have primary personal endings. Nevertheless its meaning overlaps that of the other forms, and some excellent authorities, like Professor W. W. Goodwin, see in future indicative, subjunctive and optative only different degrees of remoteness in the future, the remoteness being least in the future and greatest in the optative. Delbrück, however, abides, with slight modifications, by the distinction which he propounded in 1871 that the subjunctive expresses Will and the optative Wish. Here again the problem has not been solved, and it is doubtful how far any definite solution is likely to be arrived at, since there are so many gaps in our knowledge of mood forms. These gaps, owing to the break-up of the system at so early a period, it is hardly probable we shall ever be able to fill. It is possible, however, to do a great deal more than has yet been done even in the most familiar languages. In Latin, for instance, even now, the facts for the uses of the moods within the two centuries of the classical period are very imperfectly known, and it is no exaggeration to say that more has been done in the last hundred years for Sanskrit than has been done in two thousand years of continuous study for Latin or Greek.

A still later addition to the domain of Philology—the study of meaning—presents fewer difficulties, but until recent years has been equally neglected. The study is so recent that the literature on the subject is still extremely small. The only attempts to deal with it on a large scale are M. Brácal's Essai de Sémantique (1897), now translated into English under the title of Semantics (1906), with a valuable introduction and appendix by Dr Postgate, and M. de la Grasserie's Essai d'une Sémantique intégrale (1908), a work which deserves mention for its attempt to make a thorough classification and a corresponding terminology for semantic phenomena, but the value of which is much diminished by hasty compilation and imperfect knowledge of many of the languages quoted. From the practical point of view many of the phenomena have been classified in works on rhetoric under the headings of Metaphor, Synecdoche and Metonymy. The psychological principle behind this superficial classification is that of association of ideas. Here, as elsewhere, changes proceed not by accident, but according to definite principles. Here, as elsewhere in language, in history, and the other moral sciences, the particular principle in operation can be ascertained only by beginning with the result and working back to the cause. In the development of meaning much more than in phonetics is this necessarily the case. In phonetics all speakers of the same dialect start with approximately the same sound. But the same combination of sounds which we call a word does not recall the same, or at least to all persons who use that word. The idea that the phrase railway station calls up in the mind of a Londoner is very different from that which occurs to the mind of a child acquainted only with a wayside station serving the wants of a country village of a few hundred inhabitants. The word kerring suggests one idea or train of ideas to the fisherman who catches the fish, another to the merchant who purchases it from the fisherman, a third to the domestic who cooks it, and so on. To members of the same family the same word may often have widely different associations, and, if so, the metaphors for which the word will be employed will differ in each case.

For the history of meaning it is necessary to have regard to all the forms of association of ideas which psychology recognizes. These are contiguity in place or in time, resemblance and contrast. Contrast, however, as J. S. Mill and Bain have shown, is not a simple form of association, but is evolved partly from contiguity, partly from resemblance. An artificial hollow generally implies also an artificial height made of the materials excavated from the hollow. Hence in most languages some words occur with the two contrasted meanings. Thus in English we find dyke in use both for a ditch and for a mound formed by a ditch, the word ditches for a number of ditches, and, in fact, but a dialectal form of dyke. The English word dyke, however, is only one of the many difficult problems of the English language. In Scotland, on the other hand, where earthen mounds and stone walls form more frequent boundaries between fields than in England, the word dyke is now practically limited to elevated boundaries, while ditch is limited to excavated boundaries. Thus the proverb, "February fill dyke," which in England implies that the February rains will fill the ditches, is often understood in Scotland to mean that in February the snow will be level with the tops of the stone or turf walls. Similarly in Latin Tacitus can say fossas proruerunt, which can only apply to levelling raised mounds; while in Greek Xenophon also talks of the ditch (trench) thrown up (τάγρας καταθεματισθηκην). It is only natural, therefore, that other words with several meanings should be used similarly: moat, originally a mound of earth or peat, has come to mean a big ditch; while, conversely, soldiers in trenches are not so much in ditches, as the word ought to signify, as behind breastworks. Sometimes, when two actions opposed to one another are contiguous, a word seems to change to the exact opposite of its original meaning. Thus the English verb mean, which meant originally to accomplish (to cooked food), has been transferred to the necessary preliminary, to disaccustom to the breast.

Resemblances may be (i) genuine, and (a) of external appearance, or (b) of other characteristics; or (ii) fanciful or analogical. From resemblance in the external appearance of the object, the word gem, which in Latin (gemma) usually means a bud, has
come to mean first a pearl and then by extension of the meaning any precious stone. From the concentric coats which appear in both, the Latin word for a pearl (unio, acc. unioneum) appears in English as onien. Examples where the characteristics are not of external appearance are such as the German kaiser and the Russian tsar, which are descended from Julius Caesar, while the Lithuanian word for king—karolius—is Carolus, i.e. Charlemagne. So in modern Persian, Xusrev, “Lord,” comes from the Zend proper name Husravah (Chosroes). As already pointed out, the resemblances which have established a connexion between pert and impertinent (properly irrelevant) are in sound only. The same is true of the supposed relation of the verb cut to coUass, cutler and culler. While train oil really means oil in drops like tears (cf. German Träne), most people connect it with railway trains. The resemblance in some cases is merely in function. Thus, though the fir and the oak have no resemblance one to the other, the word fir is now generally identified with the Latin quercus in etymology (cf. four and quatruur), in the same way as the Latin fagus, “beech,” is with the Greek φσος, “oak,” the users of the word having, in the course of their migrations, passed from a land with oaks to a land with firs in the one case, and from a land of beeches to a land of oaks in the other. Resemblance as the basis of metaphor has a very widely extended influence on language.

The most numerous and most varied forms of change in meaning depend, however, upon the law of contiguity. Perhaps the commonest of all forms of contiguity is that where the word indicating some accompanying feature or condition replaces the word for the object referred to. In the countries that border the Mediterranean the heat of midday is accompanied and intensified by the dying away of the wind, a characteristic remarked upon by Aeschylus (Agam. 565): “What time upon his noontide couch, windless and waveless sank the sea to rest.” From the Greek word καυμ, “burning heat,” arises through Late Latin the English calm, where the absence of wind is the only idea present, that of heat having altogether disappeared. Again, in bugle, which is abbreviated for buglehorn, the word which survives properly means wild ox, and the originally more important element is lost. In a combination like silver bugle the word has gone a stage further; the original meaning of horn has also disappeared. There is no longer any thought of an animal’s horn; the only idea that survives is that of a musical instrument. From the cope or cloak (capella) of St Martin, which was preserved as a sacred relic by the Frankish kings, comes the word chapel. The word was first transferred from the cloak to the holy place wherein it was kept, and thence to similar shrines, and ultimately to any place, not being, as the prefix indicated, the place where prayers were said. A fig was originally not the dance, but the fiddle which supplied the music for the dance. The names of liquors are often replaced by some accomplishment as of the place, port, sherry, champagne, or by a qualifying adjective as in brandy, properly “burnt,” from the Dutch brandewijn; or, again, only the less important element of the word is retained as in whisky, literally “water,” for the older usquebaugh, a corruption of Gaelic words meaning the “water of life” (aqua vitae). Replacement of substantives by their accompanying adjectives is common in most languages. One of the most common methods of coining a name for a new article is to give it the name of the place or people whence it comes. Thus we have arras, lawn (from Laon), cravat (Croat), coach from Kocs in Hungary, bilboes (both fitters and swords) from the iron mines of Bilboa in Spain. Equally common are the names of inventors or producers—turk (i.e. the Turk) for the cutlass, guillotine, for the guillotine. In the word cash, which comes indirectly from Latin capsa, “a box,” the thing contained has taken its name from the container. Similarly mortar, “cement,” derives its name from the mortar in which it was mixed, and in box the material (boxwood, Lat. buxus, Greek κόος) has usurped the place of the article made. In leper the disease. (Lat. lepra, the rough disease, from Greek λεπανοοοο) has been made into the name of the sufferer, who was earlier called a leprous man. As a consequence, a new substantive leprosy has to be taken from the adjective to indicate the disease. The various changes in meaning, which are classed together as synecdoche, have their origin in contiguity. Thus we have the species for the genus; the butcher, who properly kills goats only (Old French boe), has ousted the flesher. But we have also the genus for the species; corn, as a rule, means in England wheat; in Scotland oats; in America, maize. The individual becomes collective as in corps, navy, body (of men); the collective becomes individual when Latin racemus, “bunch of grapes,” passes into English “raisin.” Here would come the so-called meliorative and pejorative developments in word-meaning, whereby, e.g. steward, “the stay-ward,” becomes the title of a great officer of the realm and the name of a line of kings; or, on the other side, sou (Latin solidus) passes from the name of a gold coin to that of one of proverbially insignificant value. Here, too, would come many euhemeristic uses which are, for the most part, applications of more general terms to avoid the mention of some specific act or object which is unpleasant, as death, murder, bankruptcy, debt, &c., while metaphorical terms for the same things come under resemblance. These examples do not exhaust the forms of contiguity which appear in language, but they are enough to show how far-reaching the effect of this type of association of ideas is upon language, and how extensive the field is which still calls for investigation before the study of meaning attains the same development as the investigation of the other branches of the history of language.

Authorities (since 1885).—For methods of Linguistic Study: Paul, Principien der Sprachgeschichte (3rd ed., 1898); Von der Gabelentz, Die Sprachwissenschaft (2nd ed., 1901); Strong, Legeman & Wheeler, The History of Language (1894), an adaptation of Paul’s Principien, with many excellent examples; van Ginneken, Principes de Linguistique psychologique (1907). For the Controversy regarding Phonetic Laws: Curtius, Zur Kritik der neuesten Sprachforschung; Brugmann, Zum heutigen Stand der Sprachwissenschaft; Schuchardt, Uber die Lautesetzung: gegen die Junggrammatiker (all in 1885); Tarbell, “Phonetic Law,” in Transactions of American Philological Association for 1886, pp. 1 sqq.; Wechsler, “Gibt es eine phonetische Methode?” (1900); Pemberton, “Phonetics,” in the Annual Report of the American Academy of Sciences. For other works on Phonetics, see further bibliography. As a number of volumes have appeared since 1890 will be found in the Anzeiger fur indogermanische Sprach- und Altertumskunde: Beiblatt zu den indogermanischen Forschungen redigirt, by W. Streitberg. (P.Gi.: E.SL.)

Summary of Philological Articles

In addition to the genetic classification of languages given above (on pp. 426-429), some further guidance as to the actual headings under which the philological section is arranged may be of service to the student.

The pivot of the whole section is the article Alphabet, which traces the history of language and writing to the earliest stages, ending the discussion of the Indo-European Languages: Brugmann and Dellbrück, Grundriss der vergleichenden Grammatik der indogermanischen Sprachen (1886-1900); a new edition of the Phonology by Brugmann in 1897, of the stem-formations and inflexion of Nouns, Adjectives, Pronouns and Numerals (1896), and in the last edition of all the phonological and morphological sections, translated into English in four volumes by Wright, Conway and Rouse. For Discussion of Contested Points: Bechtel, Die Hauptprobleme der indogermanischen Sprachgeschichte (1901), one of the leading works on the subject of the Languages of the Indo-European stock, or the Indo-European languages, is given. In the text. For Semantics: besides Brocé and Postgate, see Wundt, Die Völkerpsychologie, vol. i. pt. 2, and articles by John Green in the Journal of Philology, vol. iv. v. A bibliography of the works (1901) which have appeared since 1890 will be found in the Anzeiger für indogermanische Sprach- und Altertumskunde: Beiblatt zu den indogermanischen Forschungen redigirt, by W. Streitberg. (P.Gi.: E.SL.)
PHILOLOGY

WRITING deals, chiefly from the anthropological standpoint, with primitive attempts to record ideas in an intelligible form, e.g. with "knot-signs," "message-sticks," picture-writing and the like. PHOENETICS covers the whole subject of speech sounds and pronunciation, the organs of speech and national sound systems.

Supplementary, from another point of view, to the article ALPHABET is a complete series of articles on the letters of the English alphabet. In these articles the history of the individual letters is traced from the Phoenician through Aramaic, Greek and Roman to modern times. All these articles may be read in connexion with a comparative table in the article ALPHABET (ad fn.), which shows in parallel columns the earliest equivalents of the modern English letters, i.e. Brahmi, Kharaśṭh, oldest Āethiopica, Sabrene, Nashkī, Tema, Sindjīrī, the Moaite stone, Phoenician, Greek, Latin, Cyrillic and Glagolitic. Another important comparative table of written signs is contained in the article SLAVS, showing the various Cyrillic, Glagolitic and Latin letters used by the Slav peoples.

Passing from articles dealing with the method and general subject-matter of philology, the student will find articles on the great families of languages, each with its subordinate and regional languages and dialects.

1. Indo-European Languages.—Of articles on language-families, the most important is that under the heading Indo-European Languages. This great division, which is dealt with from the comparative standpoint in the second part of the article PHILOLOGY, is under its own heading treated in detail. The article begins with a sub-classification into two main groups—the so-called A and B or satem groups—each of which is further divided into four sections. In accordance with this classification there are separate articles on the individual ancient and modern languages and dialects.

A. (1) Greek Language (supplemented by sections under Homer, Dorians, &c.); (2) Latin Language (with Osca Lingua, Igisuem, &c., and articles on the Italic tribes and places, e.g. Veneti, Caere); (3) Celtic, s.e. CELT (with subsidiary articles); and (4) Teutonic, s.e. TEUTONIC LANGUAGES, SCANDINAVIAN LANGUAGES, and the like.

The modern descendants of these languages are all further treated separately. Thus following Latin Language is the article Romance Languages, which traces the development of the Latin tongue during its gradual differentiation into Italian, French, Spanish, Rumanian, &c.; while a more detailed account of these will be found under Italian Language; French Language; Spanish Language; Rumanian Language. There is also a special article PROVENÇAL LANGUAGE, dealing with the Romance speech of southern France. The Teutonic languages are similarly dealt with in detail under English Language (including Anglo-Saxon); Dutch Language; German Language. Scandinavian Language itself includes Icelandic, Norwegian, Swedish, Danish.

B. In the satem group of the Indo-European family the four divisions are as follows:

(1) Indo-Iranian or Aryan. This division may be subdivided into (a) Indo-Iranian, treated mainly in the article PERSIAN: Language and Literature (including Zend, Old, Middle and New Persian, and the modern dialects), and (b) Indian. The Indian languages are discussed primarily under Indo-Aryan Languages, which describes the relations of Pisaca, Sanskrit, Prakrit, and gives a paradigm of the various languages of the three great divisions of India. This central article refers to the separate articles Pisaca, Sanskrit, Prakrit, which in turn are supplemented by a number of articles on particular languages. Of these reference may be made to Bengali; Bihari; Gujarati and Rajasthani; Hindustani; Kashi-Miri; Marathi; Pali. The gipsy languages, which may probably be assigned to the Indo-Iranian division, are described under Gipsies.

(2) The account of Armenian will be found under ARMEonian Language and Literature.

(3) The Balto-Slavonic. Of these the three comprised in the Baltic group, viz. Lithuanian, Lettish and Old Prussian, are described under the heading LITHUANIANS and LETTS. For the Slavonic group, the chief article is SLAVS: Language, which deals with the elements common to all the Slavonic tongues, with their early history and differentiation. It contains a comparative table of alphabets. It is supplemented by an article OLD SLAVONIC, and by further information under the headings RUSSIA, BULGARIA, SERBIA, POLAND, BOHEMIA, CROATIA-SLAVONIA, SLOVAKS, SLOVENES, SORBS, KASHEUES, POLARS.

(4) The Albanian dialects are treated under ALBANIA.

2. Semitic Languages.—At the heading of this section stands the article SEMITIC LANGUAGES, supplemented by HEBREW LANGUAGE, ARAMAIC LANGUAGES, and linguistic sections under PHOENICIA, ETHIOPIA, and the like.

3. HAMITIC Languages.—The central article in this family is HAMITIC LANGUAGES, which is supplemented, so far as the Cushitic or Ethiopian group is concerned, by further information in the articles EGYPT; ETHIOPIA; ABYSSINIA; SOMALILAND; and, so far as the Libyan group is concerned, by the articles BERBERS and KABYLES.

The chief feature of the Monosyllabic family is the section Language under CHINA, supplemented again by similar sections in articles on other countries of south-eastern Asia, and by the article TIBETO-BURMAN LANGUAGES. There is also a language section under Japan which discusses the affinities between Chinese, Korean and Japanese.

5. The Ural-Altaic family is described in outline in the article URAL-ALTAIC, which gives the general relationships of Turkish, Finno-Ugrian, Mongol and Manchu, and of minor subdivisions such as Sryyenian, Mordvinian and Votyak. Turkish is discussed in the article TURKS: Language, which deals with Osmanli proper and the Tatar-Turkish languages generally. The article FINNO-UGRIAN is a comparative survey dealing with the language of the Finns, Lapps, Samoyedes, &c.; while Magyar is treated separately in HUNGARY: Language. Under MONGOLS there is a special section LANGUAGE, discussing the three groups of East Mongolia, West Mongol (including Kalmuck) and Buriat.

6. The principal languages of southern India, e.g. Tamil, Malayalam, Kanarese, Telugu, &c., are dealt with generally under the heading Dravida; while there is a separate article TAMIL, containing a section on their language; and brief notes under the headings Brahui, Telugu, Malayalam, &c. and 7 and 8. The scattered languages of the Malay-Polynesian family and other Oceanic peoples are treated principally in the article MALAYS, which further information is given under the headings POLYNESIA; SAMOA; JAVA; NEGRITOS, BATTAS, &c.

9. The Caucasian family is described chiefly in the article GEORGIA: Ethnology. Further information will be found in CAUCASIA: Ethnology.

10. Of the remaining European languages only two need special mention: Basque, which is treated in a special section under the heading BASQUES; and the lost Etruscan, which is treated under ETRUSCA and LATIN LANGUAGE.

11. The principal languages of southern and central Africa are treated fully under BASTU LANGUAGES. There is a brief account of the Bushman language under BUSHMEN, and of the Hottentot languages under HOTTENTOTS.

12. Intermediate African Languages.—Among the numerous languages spoken by the people of the great central belt of the African continent, the most important is the Hausa, described under that heading.

13. America.—The whole question of the languages of the North American Indians is dealt with in the article INDIANS, NORTH AMERICAN, which contains an elaborate linguistic paradigm.

Bibliographical information will be found in practically all the above headings. In addition to the most modern authorities there quoted, there will be found in the article DICTIONARY a very full list of older lexicographical works.

The above summary does not purport to present dogmatically a rigid philological classification. It disregards many problems, and is intended solely to enable the student readily to find the material of which he may be in search.
PHILOSOPHY

The more certain writings of Philoponus consist of commentaries on Aristotle. These include works on the Physics, the Prior and the Posterior Analytics, the Meteorologica, the De anima, the De generationis animalium, the De generatione et interiui, and the De metaphysica. These have been frequently edited and they are often referred to as "philosophy" because of the adoption of Aristotelianism by the Christian Church. They seem to have embodied the lectures of Ammonius with additions by Philoponus, and are remarkable rather for elaborate care than for originality. He wrote also an treatise on Aristotle's Physics (De adermate mundi). Two treatises on mathematics are ascribed to him: A Commentary on the Mathematics of Nicomachus, edited by Hoche (1864 and 1867), and a Treatise on the Use of the Almagest, published in 1867. The latter is the most ancient work on this instrument, and its authenticity is rendered almost certain by its reference to Ammonius as the master of the author.

PHILOSOPHY (Gr. φιλοσοφία, fond of, and σοφία, wisdom), a general term whose meaning and scope have varied very considerably according to the usage of different authors and different ages. It can best be explained by a survey of the steps by which philosophy differentiated itself, in the history of Greek thought, from the idea of knowledge and culture in general. These steps may be traced in the gradual specification of the term. The tradition which assigns the first employment of the Greek word φιλοσοφία to Pythagoras has hardly any claim to be regarded as authentic; and the somewhat self-conscious modesty to which Diogenes Laërtius attributes the choice of the designation is, in all probability, a piece of etymology crystallized into narrative. It is true that, as a matter of fact, the earliest uses of the word (the verb φιλοσοφεῖν occurs in Herodotus and Thucydides) imply the idea of the pursuit of knowledge; but the distinction between the σοφία, or wise man, and the φιλόσοφος, or lover of wisdom, appears first in the Platonic writings, and lends itself naturally to the so-called Socratic irony. The same thought is to be found in Xenophon, and is doubtless to be attributed to the historical Socrates. But the word soon lost this special implication. What is of real interest to us is to trace the progress from the idea of the philosopher as occupied with any and every department of knowledge to that which assigns him a special kind of knowledge as his province.

A specific use of the word first meets us in Plato, who defines the philosopher as one who apprehends the essence or reality of things in opposition to the man who dwells in appearances and the shows of sense. The philosophers, he says, "are those who are able to grasp the eternal and immutable"; they are "those who set their affections on that which in each case really exists" (Rep. 480). In Plato, however, this distinction is applied chiefly in an ethical and religious direction; and, while it defines philosophy, so far correctly, as the endeavor to express what things are in their ultimate constitution, it is not yet accompanied by a sufficient differentiation of the subsidiary inquiries by which this ultimate question may be approached. Logic, ethics and physics, psychology, theory of knowledge and metaphysics are all fused together by Plato in a semi-religious synthesis. It is not till we come to Aristotle—the encyclopaedist of the ancient world—that we find a demarcation of the different philosophic disciplines, corresponding, in the main, to that still current. The earliest philosophers, or "physiologers," had occupied themselves chiefly with what we may call cosmology; the one question which covers everything else. Whatever is that underlying substance of the world around them, and they essay to answer this question, so to speak, by simple inspection. In Socrates and Plato, on the other hand, the start is made from a consideration of man's moral and intellectual activity; but knowledge and action are confused with one another, as in the Socratic doctrine that virtue is knowledge. To this correspond the Platonic confusion of logic and ethics and the attempt to substitute a theory of concepts for a metaphysic of reality. Aristotle's methodic intellect led him to separate the different aspects of reality here confounded. He became the founder of logic, psychology, ethics and aesthetics as separate sciences; while he prefixed to all such (comparatively) special inquiries the investigation of the ultimate nature of existence as such, or of those first principles which are common to, and presupposed in, every narrower field of knowledge. For this investigation Aristotle's most usual name is "first philosophy" or, as a modern might say, "first principles"; but there has since been appropriated to it, apparently by accident, the title "metaphysics," "Philosophy," as a term of general application, was not, indeed, restricted by Aristotle or his successors to the disciplines just enumerated. Aristotle himself includes under the title, besides mathematics, all his physical inquiries. It was only in the Alexandrian period, as Zeller points out, that the special sciences attained to independent cultivation. Nevertheless, as the mass of knowledge accumulated, it naturally came about that the name "philosophy" ceased to be applied to inquiries concerned with the particular as such. The details of physics, for example, were abandoned to the scientific specialist, and philosophy restricted itself in this department to the question of the relation of the physical universe to the ultimate ground or author of things. This inquiry which was long called "rational cosmology," may be said to form part of the general subject of metaphysics, or at all events a pendant to it. By the gradual sifting out of the special sciences philosophy thus came to embrace primarily the inquiries grouped as "metaphysics" or "first philosophy." These were remarks in the first period of the Wolffian scheme long current in philosophical textbooks, one way, proper, or the science of being such, with its three-branch sciences of (rational) psychology, cosmology and (rational or natural) theology, dealing with the three chief forms of being—the soul, the world and God. Subsidiary to metaphysics, as the central inquiry, stand the sciences of logic and ethics, to which may be added aesthetics, constituting three normative sciences—sciences, that is, which do not, primarily, describe facts, but rather prescribe ends or set forth ideals. It is evident, however, that if logic deals with conceptions which may be considered constitutive of knowledge as such, and if ethics deals with the harmonious realization of human life, which is the highest known form of existence, both sciences must have a great deal of weight in the settling of the general question of metaphysics.

In sum, then, we may say that "philosophy" has come to be understood at least in modern times as a general term covering the various disciplines just enumerated. It has frequently tended, however, and still tends, to be used as specially convertible with the narrower term "metaphysics." This is not unnatural, seeing that it is only so far as they bear on the one central question of the nature of existence that philosophy spreads its mantle over psychology, logic or ethics. The particular organic conditions of perception and the associative laws to which the mind, as a part of nature, is subjected, are facts in themselves indifferent to the philosopher; and therefore the development of psychology into an independent science, which took place during the latter half of the 19th century and may now be said to be complete, represents an entirely natural evolution. Similarly, logic, so far as it is an art of thought or a doctrine of fallacies, and ethics, so far as it is occupied with a natural history of impulses and moral sentiments, do neither of them belong, except by courtesy, to the philosophic province. But, although this is so, it is perhaps hardly desirable to deprive ourselves of the use of two terms instead of one. It will not be easy to infuse into so abstract and bloodless a term as "metaphysics" the fullness (and especially the inclusion of ethical considerations) suggested by the more concretely homogeneous term "philosophy.

We shall first of all, then, attempt to differentiate philosophy from the special sciences, and afterwards proceed to take up one by one what have been called the philosophical sciences, with the view of showing how far the usual subject-matter of each is really philosophical in its bearing, and how far it belongs rather to the domain of "science" strictly so called. The order in which, for clearness of exposition, it will be most convenient to consider these disciplines will be psychology, epistemology or theory of knowledge, and metaphysics, then logic, aesthetics and ethics. Finally, the connexion of the last-mentioned with politics (or, to speak more modernly, with jurisprudence and sociology), with the philosophy of history and the philosophy of religion, will call for a few words on the relation of these sciences to general philosophy.
PHILOMEL—PHILOPONUS

439

PHILOMEL (Fr. Philomèle; Ger. Philomale or Stahlgeige), a musical instrument similar to the violin, but having four steel, wire strings. The phialmel has a body with incursions similar to those of the guitar; therefore, without corner blocks, the outline of the upper lobe forms a wavy shoulder reminiscent of the viols but more ornate and fanciful. The peg-box sometimes terminates in a fancy head instead of a scroll. The phialmel, never used in the orchestra, is the instrument of the dilettante, frequently played in Germany with the bowed zither. The accordance of the phialmel is the same as for the violin; the timbre is shrill and crystal-like. There is also an alto phialmel corresponding to the viola. The bowed melodic is similar to the phialmel, and has four steel strings of the same accordance as the violin, but arranged in inverse order; instead of being held like the violin and phialmel, under the chin, it is placed on the knees of the performer, so that a hook under the finger-board rests against the table.

PHILON, Athenian architect of the 4th century B.C., is known as the planner of two important works—the portico of the great Hall of the Mysteries at Eleusis and an arsenal at Athens. Of the last we have exact knowledge from an inscription. E. A. Gardner (Ancient Athens, p. 557) observes that it “is perhaps known to us more in detail than any other lost monument of antiquity.” It was to hold the rigging of the galleys; and was so contrived that all its contents were visible from a central hall, and so liable to the inspection of the Athenian democracy.

(See Athens.)

PHILOPATRIS, the title of a dialogue formerly attributed to Lucian, but now generally admitted to be spurious. Its date and purport have long formed the subject of discussion. The scene is laid at Constantinople. A certain Triphon, who has been converted to Christianity by a bald, long-nosed Galilæan, who was carried up through the air into the third heaven (an evident allusion to St Paul), meets a friend, Critias, who is in a state of great excitement. Triphon inquires the reason, and the invocation of Zeus by Critias leads to a discussion on paganism and Christianity, in which all the gods proposed by Critias are rejected by Triphon, who finally suggests that Critias should swear by the Trinity. (The sub-title, διαδοχωρον, refers to this “instruction” of Critias in matters relating to Christianity.) Critias goes on to relate how he had been introduced to a gathering of pessimists, who predicted all kinds of disturbances in the empire and defeat at the hands of its enemies. In the meantime a third person appears on the scene, with the news that the imperial armies had obtained a glorious victory. The hope is expressed that Babel (Bagdad, the chief city of the caliphs) may soon be destroyed, Egypt subdued (that is, reconquered from the Arabs), and the attacks of the Scythians (Russians or Siberians) repulsed. The whole concludes with thanks to the unknown god of Athens that they have been permitted to be the subjects of such an emperor and the inhabitants of such an empire. The Philopatris was for a long time regarded as an attack upon Christianity, and assigned to the time of Julian the Apostate (emperor 361–363). Chronological indications (e.g. the allusion to a massacre of women in Crete) led Niebuhr to ascribe it to the reign of Nicephorus Phocas (963–969), and this view is now generally supported. There being at that time no pagans in Constantinople, the “pessimists” referred to must be Christians—either monks, especially the intimate friends of the patriarch of Constantinople, who, aggrieved at the measures taken by Phocas in regard to the property of the Church, were ready to welcome the defeat of the imperial arms and the ruin of the empire; or harmless visionaries, who claimed to predict the future by fasting, prayer and visions. In any case, as the author, whether he was a sociable companion of the monks, or some professor who hoped to profit by singing the imperial praises, represents the views of the “patriotic” (as the title shows) as opposed to the “unpatriotic” party. According to another view, which assigns the dialogue to the time of Heraclius (610–641), the author was a Christian fanatic, whose object was to make known the existence of a conventicle of belated pagans, the enemies alike of the Christian faith and the empire; it is doubtful, however, whether such a pagan community, sufficiently to be of importance, actually existed at that date. The object of the first and longer portion of the dialogue was to combat the humanism of the period, threatened which, perils of polytheism as a rival of Christianity.

PHILOPOEMEN (253–184 B.C.), Greek general, was born at Megalopolis, and educated by the academic philosophers Ecdemus and Demophanes or Megalophanes, who had distinguished themselves as champions of freedom. Avoiding the fashionable and luxurious gymnasia, he devoted himself to military studies, hunting and border forays. In 233–232 B.C., Philopomen skillfully evacuated Megalopolis before the attack of Cleomenes III, and distinguished himself at Sellasia (222). The next eleven years he spent as a condottiere in Crete. Elected commander of the League’s cavalry on his return, he reorganized that force and defeated the Aetolians on the Elean frontier (210). Appointed to the chief command two years later, he introduced heavy armour and close formation for the infantry, and with a well-trained army beat Machanidas of Sparta, near Mantinea. The new “liberator” was now so famous that Philip V. of Macedon attempted to poison him. In 202–201 B.C. Philopomen drove Nabis, the Spartan tyrant, from Messene and routed him off Tegea. After another long sojourn in Crete he again received the command against Nabis. Though unsuccessful at sea, he almost annihilated Nabis’s land force near Gythium, but was prevented by the Roman Flamininus from taking Sparta. In 190 Philopomen protected Sparta, which meanwhile had joined the League and thereupon seceded, but punished a renewed defection so cruelly as to draw the censure of Rome upon his country. At Messene he likewise checked a revolt (189), but when that city again rebelled, in 184, he was captured in a skirmish and promptly executed. His body was recovered by the Achaeans and buried with great solemnity.

Philopomen’s great merit lies in his having restored to his compatriots that military efficiency without which the Achaean League for all its skilful diplomacy could never stand. Towards Rome he advocated a courteous but independent attitude. In politics he was a democrat, and introduced reforms of a popular character (see Achaean League).

Polybius’ Histories (x.–xxiii.) are our chief authority. These and a special treatise on Philopomen (now lost) were used by Plutarch (Philopomen), Pausanias (viii. 49–51), Livy (xxx.–xxxviii.), and indirectly by Justin (xxx.–xxxvii.).

PHILOPONUS, JOANNE ( JOHN THE GRAMMARIAN), Greek philosopher of Alexandria, lived in the later part of the 5th and the beginning of the 6th century of our era. The surname Grammaticus he assumed in virtue of his lectures on language and literature; that of Philoponus owing to the large number of treatises he composed. He was a pupil of Ammonius Hermiae, and is supposed to have written the life of Aristotle sometimes attributed to his master. To Philoponus are attributed a large number of works on theology and philosophy. It is said that, though he was a pupil of Ammonius, he was at first a Christian, and that he has been credited with the authorship of a commentary on the Mosaic Cosmogony in eight books, dedicated to Sergius, patriarch of Constantinople, and edited by Balthasar Corderius in 1630. Other authorities maintain that this, as well as the Disputatio de paschale, was the work of another author, John the Tritheist. It was perhaps this Philoponus who tried to save the Alexandrian library from the caliph Omar after Amu’s victory in 639.
PHILOSOPHY

Philosophy and Natural Science.—In distinguishing philosophy from the sciences, it may not be amiss at the outset to guard against the possible misunderstanding that philosophy is concerned with a subject-matter different from, and in some obscure way transcending, the subject-matter of the sciences. Now that psychology, or the observational and experimental study of mind, may be said to have been definitively included among the positive sciences, there is not even the apparent ground which once existed for such an idea. Philosophy, even under its most discredited name of metaphysics, has no other subject-matter than the nature of the real world, as that world lies around us in everyday life, and lies open to observers on every side. But if this is so, it may be asked what function can remain for philosophy when every portion of the field is already lotted out and enclosed by specialists? Philosophy claims to be the science of the whole; but, if we get the knowledge of the parts from the different sciences, what is there left for philosophy to tell us? To this it is sufficient to answer generally that the synthesis of the parts is something more than that detailed knowledge of the parts in separation which is gained by the man of science. It is with the ultimate synthesis that philosophy concerns itself. It seeks to show not that the subject-matter which we are all dealing with in detail really is a whole, consisting of articulated members. Evidently, therefore, the relation existing between philosophy and the sciences will be, to some extent, one of reciprocal influence. The sciences may be said to furnish philosophy with its matter, but philosophical criticism reacts upon the matter thus furnished, and transforms it. Such transformation is inevitable, for the parts only exist and can only be fully, i.e. truly, known in their relation to the whole. A pure specialist, if such a being were possible, would be merely an instrument whose results had to be co-ordinated and used by others. Now, though a pure specialist may be an abstraction of the mind, the tendency of specialists in any department naturally is to lose sight of the whole in attention to the particular categories or modes of nature's working which happen to be exemplified, and fruitfully applied, in their own sphere of investigation; and in proportion as this is the case it becomes necessary for their theories to be co-ordinated with the results of other inquirers, and set, as it were, in the light of the whole. This task of co-ordination, in the broadest sense, is undertaken by philosophy; for the philosopher is essentially what Plato, in a happy moment, styled him, σωφρόνιστος, the man who takes a "synoptic" or comprehensive view of the universe as a whole. The aim of philosophy (whether fully attainable or not) is to exhibit the universe as a rational system in the harmony of all its parts; and accordingly the philosopher refuses to consider the parts out of their relation to the whole whose parts they are. Philosophy corrects in this way the abstractions which are inevitably made by the scientific specialist, and may claim, therefore, to be the only concrete science, that is to say, the only science which takes account of all the elements in the problem, and the only science whose results can be true in more than a provisional sense.

For it is evident from what has been said that the way in which we commonly speak of "facts" is calculated to convey a false impression. The world is a complex of facts existing side by side and capable of being known separately. A fact is nothing except in its relations to other facts; and as these relations are multiplied in the progress of knowledge the nature of the so-called fact is indefinitely modified. Moreover, every statement of fact involves certain general notions and theories, so that the "facts" of the separate sciences cannot be stated except in terms of the conceptions or hypotheses which are assumed by the particular science. Thus mathematics assumes space as an existent infinite, without investigating in what sense the existence or the infinity of this Unding, as Kant called it, can be asserted. In the same way, physics may be said to assume the notion of material atoms and forces. These and similar assumptions are ultimate presuppositions or working hypotheses for the sciences themselves. But it is the office of philosophy, as a theory of knowledge, to submit such conceptions to a critical analysis, with a view to discover how far they can be thought out, or how far, when this is done, they refute themselves, and call for a different form of statement, if they are to be taken as a statement of the ultimate nature of the real. The first statement may frequently turn out to have been merely provisionally or relatively true; it is then superseded by, or rather inevitably merges itself in, a less abstract account. In this the same "facts" appear differently, because no longer separated from other aspects that belong to the full reality of the known world. There is no such thing, we have said, as an individual fact; and the nature of any fact is not fully known unless we know it in all its relations to the system of the universe, or, in Spinoza's phrase, sub specie aeternitatis. In strictness, there is but one res completa or concrete fact, and it is the business of philosophy, as science of the whole, to expound the chief relations that constitute its complex nature.

The last abstraction which it becomes the duty of philosophy to remove is the abstraction from the knowing subject which is made by all the sciences, including, as we shall see, the science of psychology. The sciences, one and all, deal with a world of objects, but the ultimate fact as we know it is the existence of a subject which is known itself. The subject is necessarily more widely, self-consciousness with its implicates—this unity in duality is the ultimate aspect which reality presents. It has generally been considered, therefore, as constituting in a special sense the problem of philosophy. Philosophy may be said to be the explication of what is involved in this relation, or, in Kantian phraseology, a theory of its possibility. Any would-be theory of the universe which makes its central fact impossible stands self-condemned. On the other hand, a sufficient analysis here may be expected to yield us a statement of the reality of things in its last terms, and thus to shed a light backwards upon the true nature of our subordinate conceptions.

Psychology, Epistemology and Metaphysics.—This leads to the consideration of the main divisions of philosophy—Psychology (q.v.), epistemology (theory of knowledge, Erkenntnistheorie), and metaphysics (ontology; see METAPHYSIC). A special relation has always existed between psychology and systematic philosophy, but the closeness of the connexion has been characteristic of modern and more particularly of English thought. The connexion is not difficult to explain, seeing that in psychology, or the science of mind, we study the fact of intelligence (and moral action), and have, so far, in our hands the fact to which all other facts are relative. From this point of view we may even see a truth in Jacobi's dictum as quoted by Sir W. Hamilton: "Nature conceals God; man reveals God." Nature by itself, that is to say, is insufficient. The ultimate explanation of things cannot be given by any theory which excludes from its survey the intelligence in which nature, as it were, gathers herself up. But knowledge, or the mind as knowing, willing, &c., may be looked at in two different ways. It may be regarded simply as a fact; in which case the evolutions of mind may be traced and reduced to laws in the same way as the phenomena treated by the other sciences. This study gives us the science of empirical psychology, or, as it is now termed, psychology sans phrase. In order to give an adequate account of its subject-matter, psychology may require higher or more complex categories than are employed in the other sciences, just as biology, for example, does not work with mechanical categories alone, but introduces the conception of development or growth. But the affinities of such a study are manifestly with the sciences as such rather than with philosophy; and the definitive establishment of psychology as an independent science has already been alluded to. Since it has been taken up by specialists, psychology is being established on a broader basis of induction, and with the advantage, in some departments, of the employment of experimental methods of measurement. But it is not of mind in this aspect

---

1 The revisionary office which philosophy here assumes constitutes her the critic of the sciences. It is in this connexion that the meaning of the definition of philosophy as "the science of principles" can best be seen. This is perhaps the most usual definition, and though vague, one of the least misleading.
PHILOSOPHY

that such assertions can be made as those quoted above. Mind, as studied by the psychologist—mind as a mere fact or phenomenon—grounds no inference to anything beyond itself. The distinction between mind viewed as a succession of "states of consciousness" and the further aspect of mind which philosophy considers was very clearly put by Croom Robertson, who also made a happy suggestion of two terms to designate the double point of view: "We may view knowledge as mere subjective function, but it has its full meaning only as it is taken to represent what we may call experience, as distinguished in different circumstances from real, valid, true. As mere subjective function, which it is to the psychologist, it is best spoken of by an unambiguous name, and for this there seems none better than Intellation. We may then say that psychology is occupied with the natural function of Intellation, if we would discover its laws and distinguishing its various modes (perception, representative imagination, conception, &c.) according to the various circumstances in which the laws are found at work. Philosophy, on the other hand, is theory of Knowledge (as that which is knowable, i.e., metaphysics proper)."

The confusion of these two points of view has led, and still leads, to serious philosophical misconception. It is hardly an exaggeration to say that, in the English school since Hume, psychology superseded properly philosophical inquiry. And we find even a thinker with a wider horizon like Sir W. Hamilton encouraging the confusion by speaking of "psychology or metaphysics," while his lectures on metaphysics are mainly taken up with what belongs in the strictest sense to psychology proper, with an occasional excursus (as in the theory of perception) into epistemology. The distinction between psychology and theory of knowledge was first clearly made by Kant, who repeatedly insisted that the Critique of Pure Reason was not to be taken as a psychological inquiry. He defined his problem as the quid juris or the question of the validity of knowledge, not its quid facti or the laws of the empirical genesis and evolution of intuition (to use Croom Robertson's phraseology). Since Kant philosophy has chiefly taken the form of theory of knowledge or of a criticism of experience. Not, indeed, a preliminary criticism of our faculties or conceptions such as Kant himself proposes to institute, in order to determine the limits of their application; such a criticism ab extra of the nature of our experience is essentially a thing impossible. The only criticism which can be applied in such a case is the immanent-criticism which the conceptions or categories exercise upon one another. The organized criticism of these conceptions is really nothing more than the full explanation of what they mean and of what experience in its full nature or notion is. This constitutes the theory of knowledge in the only tenable sense of the term, and it lays down, in Kantian language, the conditions of the possibility of experience. These conditions are the conditions of knowledge as such, or, as it may be put, of objective consciousness—of a self-consciousness of a world of objects and through them conscious of itself. The inquiry is, therefore, logical or transcendental in its nature, and does not entangle us in any decision as to the conditions of the genesis of such consciousness in the individual. When we inquire into subjective conditions we are thinking of facts causing other facts, in whose agencement or transcendental causation we are or can be conscious. They are the conceptions of knowledge. The doctrine of knowledge—its foundation, its development, its limits, its proof—this is the criticism of knowledge which is Kant's contribution to philosophy. The doctrine of knowledge—its foundation, its development, its limits, its proof—this is the criticism of experience which is Kant's contribution to philosophy. We return to the distinction between epistemology and psychology, by way of illustrating the nature of the former, we may take the following summary up by Professor James Ward in a valuable article on "Psychological Principles" in Mind (April 1883, pp. 166, 167): "Comparing psychology and epistemology, we may say that the former is essentially genetic in its method, and might, if we had the power to revise our existing terminology, be called biology; the latter, on the other hand, is essentially devoid of everything historical, and treats, sub specie aternitatis, as Spinoza might have said, of human knowledge, conceived as the possession of mind in general."

Kant's problem is not, in its wording, very different from that which Locke set before him when he resolved to "inquire into the original, certainty and extent of human knowledge together with the grounds and degrees of belief, opinion and assent." Locke's Essay is undoubtedly, in its intention, a contribution to the theory of knowledge. But, because time had not yet made the matter clear, Locke suffered himself to digest his second book into the psychological question of the origin of our ideas; and his theory of knowledge is ruined by the failure to distinguish metaphysical from epistemological questions. It is said that Locke supposed content and the psychological sense in which it is applied to a fact or process in the individual mind. The same confusion runs through Berkeley's arguments and vitiates his conclusions as well as those of Hume. But appearing with these thinkers as the problem of perception, epistemology widens its scope and becomes, in Kant's hands, the question of the possibility of experience in general. With Hegel it passes into a more completely articulated logic, which apparently claims to be at the same time a metaphysic, or an ultimate expression of the nature of the real.

This introduces us to the second part of the question we are seeking to determine, namely the relation of epistemology to metaphysics. It is evident that, as philosophy as theory of knowledge must have for its complement philosophy as metaphysics (ontology) or theory of being. The question of the truth of our knowledge, and the question of the ultimate nature of what we know, are in reality two sides of the same inquiry; and therefore our epistemological results have to be ontologically expressed. It is not every thinker that can see his way with Hegel to assert in set terms the identity of thought and being. Hence the theory of knowledge becomes with some a theory of human ignorance. This is the case with Herbert Spencer's doctrine of the Unknowable, which he advances as the result of epistemological considerations in the philosophical prolegomena to his system. Very similar positions were maintained by Kant and Comte; and, under the name of "agnosticism" (q.v.), the theory has popularized itself in the outer courts of philosophy, and on the shifting borderland of philosophy and literature. The truth is that the habit of thinking exclusively from the standpoint of the theory of knowledge tends to beget an undue subjectivity of temper. And the fact that it has become usual for men to think from this standpoint is very plainly seen in the almost universal description of philosophy as an analysis of experience, instead of its more old-fashioned designation as an inquiry into the nature of things. As it is matter of universal agreement that the problem of being must be attacked indirectly through the problem of knowledge, this substitution may be regarded as an advance, more especially as it implies that the fact of experience, or of self-conscious existence, is the chief fact to be dealt with. But if so, then self-consciousness must be treated as itself real, and as organically related to the rest of existence. If self-consciousness be treated in this objective fashion, then we pass naturally from epistemology to metaphysics or ontology. (For, although the term "ontology" has been as good as disused, it still remains true that the aim of philosophy must be to furnish us with an ontology or a coherent and adequate theory of the nature of reality.) But if, on the other hand, knowledge and reality are ab initio opposed to one another—if consciousness be set on one side as over against reality, and merely holding up a mirror to it—then it follows with equal naturalness that the truly real must be something which lurks unrevealed.
PHILOSOPHY

behind the subject's representation of it. Hence come the different varieties of a so-called phenomenology. The upholders of such a theory would, in general, derive the term "metaphysics" or "ontology"; but it is evident, none the less, that their position itself implies a certain theory of the universe and of our own place in it, and the establishment of this theory constitutes their metaphysics.

Without prejudice, then, to the claim of epistemology to constitute the central philosophic discipline, we may simply note its liability to be pressed too far. The exclusive preoccupation of men's minds with the question of knowledge during the neo-Kantian revival in the 'seventies of the last century drew from Lotze the caustic criticism that "the continual sharpening of the knife becomes tiresome, if after all, we have nothing to cut with it." Stillself's complaint against Locke was that he "one of the gentlemen of this new way of reasoning that have almost discarded substance out of the reasonable part of the world." The same may be said with greater truth of the devotees of the theory of knowledge; they seem to have no need of so old-fashioned a commodity as reality. Yet, after all, Fichte's dictum holds good. Locke's knowledge of knowledge is looked at as knowledge of the ipso facto, not reality. The result of the foregoing, however, is to show that, as soon as epistemology draws its conclusion, it becomes metaphysics; the theory of knowledge passes into a theory of being. The ontological conclusion, moreover, is not to be regarded as something added by an external process; it is an immediate implication. The metaphysic is the epistemology from another point of view—regarded as completing itself, and explaining in the course of its exposition that relative or practical separation of the individual knower from the knowable world, which it is a sheer assumption to take as absolute. This, not the so-called assumption of the implicit unity of being and thought, is the really unwarrantable postulate; for it is an assumption which we are obliged to retract bit by bit, while the other offers the whole doctrine of knowledge as its voucher.

Logic, Aesthetics and Ethics. If the theory of knowledge thus passes insensibly into metaphysics it becomes somewhat difficult to assign a distinct sphere to logic (q.v.). Ueberweg's definition of it as "the science of the regulative laws of thought" (or "the normative science of thought") comes near enough to the traditional sense to enable us to compare profitably the usual subject-matter of the science with the definition and end of philosophy. The introduction of the term "regulative" or "normative" is intended to differentiate the science from psychology as the science of mental processes or events. In this reference logic does not tell us how our intellects connect themselves as mental phenomena, but how we ought to connect our thoughts if they are to realize truth (either as consistency with what we thought before or as agreement with observed facts). Logic, therefore, goes epistemology (and differs from psychology) in treating thought not as mental fact but as knowledge, as idea, as having meaning in relation to an objective world. To this extent it must inevitably form a part of the theory of knowledge. But, if we desire to keep by older landmarks and maintain a distinction between the two disciplines, a ground for doing so may be found in the fact that all the main definitions of logic point to the investigation of the laws of thought in a subjective reference—with a view, that is, by an analysis of the operation, to ensure its more correct performance. According to the old phrase, logic is the art of correct thinking. Moreover we commonly find the statistician assuming that the process of thought has advanced a certain length before his examination of it begins; he takes his material full-formed from perception, without, as a rule, inquiring into the nature of the conceptions which are involved in our perceptive experience. Occupying a position, therefore, within the wider sphere of the general theory of knowledge, ordinary logic consists in an analysis of the nature of general statement, and of the conditions under which we pass validly from one general statement to another. But the logic of the schools is eked out by contributions from a variety of sources (e.g. from grammar on one side and from psychology on another), and cannot claim the unity of an independent science.

Aesthetics (q.v.) may be treated as a department of psychology or, in England this is the mode of treatment that has been most general. To what peculiar excitation of our bodily or mental organism, it is asked, are the emotions due which make us declare an object beautiful or sublime? And, the question being put in this form, the attempt has been made in some cases to explain away any peculiarity in the emotions by analysing them into simpler elements, such as primitive organic pleasures and prolonged associations of usefulness or fitness. But, just as psychology in general cannot do duty for a theory of knowledge, so it holds true of this particular application of psychology that a mere reference of these emotions to the mechanism and interactive play of our faculties cannot be regarded as an account of the nature of the beautiful. Perhaps by talking of "emotions" we tend to give an unduly subjective colour to the investigation; it would be better to speak of the perception of the beautiful. Pleasure in itself is unqualified, and affords no differentia. In the case of a beautiful object the result of pleasure borrows its specific quality from the presence of some determinations customarily objective in their nature, but not reducible to the categories of science. Unless, indeed, we conceive our faculties to be constructed on some arbitrary plan which puts them out of relation to the facts with which they have to deal, we have a prima facie right to treat beauty as an objective determination of things. The question of aesthetics would then be formulated—What is it in things that makes them beautiful, and what is the relation of this aspect of the universe to its ultimate nature, as that is expounded in metaphysics? The answer constitutes the substance of aesthetics, considered as a branch of philosophy. But it is not given simply in abstract terms: the philosophical treatment of aesthetics includes also an exposition of the concrete phases of art, as these have appeared in the history of the world, relating themselves to different phases of human culture.

Of ethics (q.v.) it may also be said that many of the topics commonly embraced under that title are not strictly philosophical in nature. They are subjects for a scientific psychology employing the historical method with the conceptions of heredity and development, and calling to its aid, as such a psychology will do, the investigations of all the sociological sciences. To such a psychology must be relegated all questions as to the origin and development of moral ideas. Similarly, the question debated at such length by English moralists as to the nature of the moral faculty (moral sense, conscience, &c.) and the controversy concerning the freedom of the will belong entirely to psychology. If we exclude such questions in the interest of systematic correctness, and seek to determine for ethics a definite subject-matter, the science may be said to fall into two departments. The first of these deals with the notion of duty, and endeavours to define the good or the ultimate end of action; the second lays out the scheme of concrete duties which are deductible from, or which, at least, are covered by, this abstractly stated principle. The second of these departments is really the proper subject-matter of ethics considered as a separate science; but it is often conspicuous by its absence from ethical treatises. However, morals may differ on first principles, there seems to be a remarkably little practical divergence when they come to lay down the particular laws of morality. It may be added that, where a systematic account of duties is actually given, the connexion of the particular duties with the universal formula is in general more formal than real. It is only under the head of casuistry (q.v.) that ethics has been much cultivated as a separate science. The first department of ethics, on the other hand, is the branch of the subject in virtue of which ethics forms part of philosophy. As described above, it ought rather to be called, in Kant's phrase, the metaphysic of ethics. A theory of obligation is ultimately found to be inseparable from a metaphysics of personality. The connexion of ethics with metaphysics will be patent as a matter of fact, if it be remembered how Plato's philosophy is summed up in the idea of the good, and how
Aristotle also employs the essentially ethical notion of end as the ultimate category by which the universe may be explained or reduced to unity. But the necessity of the connexion is also apparent, unless we are to suppose that, as regards the course of universal nature, man is altogether an imperium in imperio, or rather (to adopt the forcible phrase of Marcus Aurelius) an abscess or excrescence on the nature of things. If, on the contrary, we must hold that man is essentially related to what the same writer calls "a common nature," then it is a legitimate corollary that in man as intelligence we ought to find the key of the whole fabric. At all events, this method of approach must be truer than any which, by restricting itself to the external aspect of phenomena as presented in space, leaves no scope for inwards and life and all that, in Lotze's language, gives "value" to the world. The argument _ex analogia hominis_ has often been carried too far; but if a "chief end of man" be discoverable—_ἀπὸθετέλους ἀγαθοῦ_, as Aristotle wisely insisted that the ethical end must be determined—then it may be assumed that this end cannot be irrelevant to that ultimate "meaning" of the universe which, according to Lotze, is the quest of philosophy. If, "the idea of humanity," as Kant called it, has ethical perfection at its core, then a universe which is really an organic whole must be ultimately representable as a moral order or a spiritual kingdom such as Leibnitz named, in words borrowed from St Augustine, a city of God.

---

**PHILOSOPHY**

The philosophy of the State (Political Philosophy), Philosophy of History, Philosophy of Religion.—In Plato and Aristotle ethics and politics are indissolubly connected. In other words, seeing that the highest human good is realizable only in a community, the theory of the state as the organ of morality, and itself in its structure and institutions the expression of ethical ideas or qualities, becomes an integral part of philosophy. The difficulty already hinted at, which individualistic systems of ethics experience in connecting particular duties with the abstract principle of duty is a proof of the failure of their method. For the concept of the state is that which it is necessary to acquire, in great part, to the experience crystallized in laws and institutions and to the unwritten law of custom, honour and good breeding, which has become organic in the society of which we are members. Plato's _Republic_ and Hegel's _Philosophie des Rechts_ are the most typical examples of a fully developed philosophy of the state, but in the earlier modern period the prolonged discussion of natural rights and the social contract must be regarded as a contribution to such a theory. Moreover, if philosophy is to complete its constructive work, it must bring the course of human history within its survey, and exhibit the sequence of events as an evolution in which the purposive action of reason is traceable. This is the task of the philosophy of history, a peculiarly modern study, due to the growth of a humanistic and historical point of view. Lessing's conception of history as an "education of the human race" is a typical example of this interpretation of the facts, and was—indeed the prerequisite which stimulated many other developments in German thought. The philosophy of history is, however, it will be observed, from the purely scientific or descriptive studies covered by the general title of sociology. Sociology conceives itself as a natural science elucidating a factual sequence. The philosophy of history is essentially teleological; that is to say, it seeks to interpret the process as the realization of an immanent end. It may be said, therefore, to involve a complete metaphysical theory. Social institutions and customs and the different forms of state-organization are judged according to the degree in which they promote the realization of the human ideal. History is thus represented by Hegel, for example, as the realization of the idea of freedom, or rather as the reconciliation of individual freedom and the play of cultured interests with the stable objectivity of law and an abiding consciousness of the greater whole in which we move. So far as the course of universal history can be truly represented as an approximation to this reconciliation by a widening and deepening of both the elements, we may claim to possess a philosophy of history. But although the possibility of such a philosophy seems implied in the postulated nationality of the universe, many would hold that it remains as yet an unachieved ideal.

There only remains to be briefly noticed the relation of philosophy to theology and the nature of what is called Philosophy of Religion. By theology is commonly understood the systematic presentation of the teaching of some positive or historical religion as to the existence and attributes of a Supreme Being, including his relation to the world and especially to man. But these topics have also been treated by philosophers and religious thinkers, without dependence on any historical data or special divine revelation, under the title of Natural Theology. Natural Theology is especially associated with the Stoic theories of providence in ancient times and with elaborations of the argument from design in the 18th century. But there is no warrant for restricting the term to any special mode of approaching the problems indicated; and as these form the central subject of metaphysical inquiry, no valid distinction can be drawn between natural theology and general metaphysics. The philosophy of religion, in the other hand, investigates the nature of the religious consciousness and the value of its pronouncements on human life and man's relation to the ground of things. Unity, reconciliation, peace, joy, the victory over the world—such, in slightly varying phrases, is the content of religious faith. Does this consciousness represent an authentic insight into ultimate fact, or is it a pitiful illusion of the nerves, born of man's hopes and fears and of his fundamentalignorance? The philosophy of religion assumes the first alternative. The function of philosophy in general is the reflective analysis of experience, and the religious experience of mankind is prima facie entitled to the same consideration as any other form of conscious activity. The certainties of religious faith are matter of feeling or immediate assurance, and are expressed in the pictorial language of imagination. It becomes the function of philosophy, dealing with these utterances, to relate them to the results of other spheres of experience, and to determine their real meaning in the more exact terms of thought. The philosophy of religion also traces in the different historical forms of religious belief and practice the gradual evolution of what it takes to be the truth of the matter. Such an account may be distinguished from what is usually called the science of religion by the teleological or metaphysical presuppositions it involves. The science of religion gives a purely historical and comparative account of the various manifestations of the religious instinct without pronouncing on their relative truth or value and without, therefore, professing to apply the idea of evolution in the philosophical sense. That idea is fundamental in the philosophy of religion, which therefore can be written only from the standpoint of a constructive metaphysical theory.

It is, indeed, only from the standpoint of such a theory that the definitions and divisions of the different philosophical disciplines adopted in this article can be said to hold good. But those who, like the positivists, agnostics and skeptics, deny the possibility of metaphysics as a theory of the ultimate nature of things, are still obliged to retain philosophy as a theory of knowledge, in order to justify the asserted limitation or impotence of human reason.

**BIBLIOGRAPHY**—The best general histories of philosophy are by J. E. Erdmann, Friedrich Ueberweg and W. Windelband, _Windelband's Handbuch der philosophischen Literatur_ (1910), and _H. A. Kallmann's Geschichte der Philosophie_ (1901). The most notable recent works are E. L. Leopold's _Hegel's System of Philosophy_ (1907) and _Karl Marx's Philosophy of Revolution_ (1909). See also W. W. Lindsay's _Gnomon_ (1901); J. S. Mill's _A System of Logic_ (1843): A. V. C. Halperin's _History of Political Thought_ (1901); J. A. G. F. Bouché's _History of Modern Philosophy_ (1900). For modern times, in addition to the general histories already named, the works of Kuno Fischer, R. F. H. T. H. Cobbing and W. H. D. Robertson, and R. A. Adamson's _Lectures on the Development of Modern Philosophy_,
PHILOSTROUS—PHILOXENUS

PHILOSTROUS, the name of several, three (or four), Greek sophists of the Roman imperial period—(1) Philostratus "the Athenian" (c. 176-243), (2) his nephew? Philostratus "the Lemnian" (b. 190), and (3) Philostratus "the Athenian," author of the Life of Apollonius Tyana, which he dedicated to Julia Domna, wife of Alexander Severus and mother of Caracalla (see APOLLONIUS OF TYANA). He wrote also Bios Zoophoros (Lives of the Sophists), Gymnastica, and Epistolae (mainly of an erotic character). Very little is known of his career. Even his name is doubtful. The Lives of the Sophists gives the praenomen Flavius, which, however, is found elsewhere only in Tzetzes. Euanius and Synesius call him a Lemnian; Photios a Tyrian; his letters refer to him as an Athenian. It is probable that he was born in Lemnos, studied and taught at Athens, and then settled in Rome (where he would naturally be called Athenienis) as a member of the learned circle with which Julia Domna surrounded herself. He was born probably in 172, and is said by Suidas to have been living in the reign of Philip (244-249). The fact that the author of Apollonius is also the author of the Lives of the Sophists is confirmed by internal evidence. The latter dedicatory consul Antonius Gorgianus, perhaps, one of the two Gorgians who were killed in 238. The work is divided into two parts: the first dealing with the ancient Sophists, e. g. Gorgias, the second with the later school, e. g. Herodes Atticus.

The Lives are not in the true sense biographical, but rather picturesque impressions of leading representatives of an attitude of mind full of curiosity, alert and versatile, but lacking scientific method, preoccupation with the eternal essence and man's place and value in the order of the Lemnian. It is a popularization on the heroes of the Trojan War in the form of a conversation between a Thracian vine-grower on the shore of the Hellespont and a Phocian merchant who derived his knowledge from the hero Protresias. Palamedes is exalted at the expense of Odysseus, and Homer's unfairness to him is attacked. It has been suggested that Philostratus here describes a series of heroic paintings in the palace of Julia Domna. His other work is the Exeles (Images), consisting of a description of 64 pictures in a Neapolitan gallery. Goethe, Welcker, Brunn, E. Bertrand and Helbig, among others, have held that the descriptions are of actually existing works of art, while Heyne and Friederich show the work of the painter is showing the way in which ancient artists treated mythological and other subjects, and are written with artistic knowledge and in an attractive language. This work is imitated by the third Philostratus (or by some later sophist) who also wrote on the subjects of transformation and identity.

There is great difficulty, due to a confused statement of Suidas, in disentangling the works and even the personalities of these Philostrati. Reference is made to Philostratus as the son of Verus, a rhetorician in Nero's time, who wrote tragedies, comedies, and treatises. Suidas thus appears to give to Philostratus the Athenian a life of 200 years! We must be content to assume two Lemnian Philostrati, both sophists, living in Rome. See further a full discussion of the works of the Bavarian,舆论Philologus, pp. 529-537.

Of works bearing the name Philostratus there is a collected edition by C. F. Kayser (Zurich, 1844; Leipzig, 1870-1871), and another by Westermann (Paris, 1849), with Latin translation; these superseded those of Schmid (Leipzig, 1680) and Kayser (Leipzig, 1718). The separate editions of the Exeles by Schmid and Richard (Leipzig, 1902); of the Gymnastica by Mylius (1858), who discovered the MS., Duremberg (Paris, 1858), Volckmar (Aurich, 1862), and especially Julius Jüttner (1909), with introd., comments and Gerard.

PHILOXENUS, of Cithera (435-380 B.C.), Greek dithyrambic poet. On the conquest of the island by the Athenians he was taken as a prisoner of war to Athens, where he came into the possession of the dithyrambic poet Melanippides, who educated him and set him free. Philoxenus afterwards resided in Sicily, at the court of Dionysius, tyrant of Syracuse, whose bad verses he declined to praise, and was in consequence sent to work in the quarries. After leaving Sicily he travelled in Greece, Italy and Asia, reciting his poems, and died at Ephesus. According to Suidas, Philoxenus composed twenty-four dithyrambs and a lyric poem on the genealogy of the Aeacidae. In his hands the dithyramb seems to have been a sort of comic opera, and the music, composed by himself, of a debased character. His masterpiece was the Cyclops, a pastoral burlesque on the love of the Cyclops for the fair Galatea, written to avenge himself on Philoxenes, who was wholly or partially blind in one eye. It was parodied by Ariosto in the Pulsus (290). Another work of Philoxenus (sometimes attributed to Philoxenes of Leucas, a notorious parasite and glutton) is the Δημητρίο (Dinner), of which considerable fragments have been preserved by Athenaeus. This is an elaborate bill of fare in verse, probably intended as a satire on the luxury of the Sicilian court. The great popularity of Philoxenus is attested by a complimentary resolution passed by the Athenian senate in 393. The comic poet Antiphanes spoke of him as a god among men; Alexander the Great had his poems sent to him in Asia; the Alexandrian grammarians received him into the canon; and down to the time of Polybius his works were regularly learned and annually acted by the Arcadian youth.

There are several manuscripts of the work, with life, by G. Bippart (1843); T. Bergk, Poetae lyrici graeci.

PHILOXENUS (Syrian, Açaknaya) of Mabgob, one of the best of Syrian prose writers, and a venerated champion of Monophysite doctrine in the end of the 5th and beginning of the 6th centuries. He was born, probably in the third quarter of the 5th century, at Taḥal, a village in the district of Bēth Garmai east of the Tigris. He was thus by birth a subject of Persia, but all his active life of which we have any record was passed in the territory of the Greek Empire. The statements that he had been a slave and was never baptized appear to be malicious inventions of his theological opponents. He was educated at Edessa, perhaps in the famous "school of the Persians," which was afterwards (in 489) expelled from Edessa² on account of its connexion with the Nestorian heresy. The years which followed the Council of Chalcedon (451) were a stormy period in the Syrian Church. Philoxenus soon attracted notice by his strenuous advocacy of Monophysite doctrine, and on the expulsion of Calandio (the orthodox patriarch of Antioch) in 485 was ordained bishop of Mabgob³ by his Monophysite successor Peter the Fuller (Barhebraeus, Chron. ecli. i. 185). It was probably during the earlier years of his episcopate that he composed his thirty-six homilies on the Christian life. Later he devoted himself to the revision of the Syriac version of the Bible, and with the help of his chrysopiscopos Polycarp produced in 568 the so-called Philoxeníon version, which was in some sense the received Bible of the Monophysites during the 6th century. Meantime he continued his ecclesiastical activity, working as a bitter opponent of

¹ As Umm Qannin is an Athenian island, none Athenian could be called an Athenian.
² According to Barhebraeus (Chron. ecli. i. 55) through the efforts of Philoxenus himself.
³ Hierapolis of the Greeks, Manbij of the Arabs, a few miles west of the Euphrates about latitude 36°N.
PHILTRE—PHLEBITIS

Flavian II., who had accepted the decrees of the Council of Chalcedon and was patriarch of Antioch from 408 to 512. The Monophysites had the sympathy of the emperor Anastasius, and were finally successful in ousting Flavian in 512 and replacing him by their partisan Severus. Of Philozenus's part in the struggle we possess not too trustworthy accounts by hostile writers, such as Theophanes and Theodorus Lector. We know that in 408 he was staying at Edessa; in or about 507, according to Theophanes, he was summoned by the emperor to Constantinople; and he finally presided at a synod at Sidon which was the means of procuring the replacement of Flavian by Severus. But the triumph was short-lived. Justin I., who succeeded Anastasius in 518, was less favourable to the party of Severus and Philozenus, and in 519 they were both sentenced to banishment. Philozenus was sent to Philippopolis in Thrace, and afterwards to Greece and Thessalonica, where he met his death by foul play in 519.

Apart from his redoubtable powers as a controversialist, Philozenus deserves commemoration as a scholar, an elegant writer, and an exponent of practical Christianity. Of the chief monuments of his scholarship—'the Philoxenian version of the Bible—only the Gospels and certain portions of Isaiah are known to survive (see Wright, Syl. Lit. 14). It was an attempt to provide a more accurate rendering of the Greek Bible than had hitherto existed in Syria, and was made among the Jews of Antioch, by the still more literal renderings of the Old Testament by Paul of Tella and of the New Testament by Thomas of Harkel (both in 616-617), of which the latter at least was based on the work of Philozenus. Aphraates is manifest both in his choice of the Gospels from his pen. Of the excellence of his style and of his practical religious zeal we are able to judge from the thirteen homilies on the Christian life and character which have been edited and translated by his later follower, Libanus. They show him holding, for the most part from theological controversy, and treats in an admirable tone and spirit the themes of faith, simplicity, the fear of God, poverty, greed, abstinence and unchastity. His affinity with his earlier countryman Aphraates is manifest both in his choice of subjects and his manner of treatment. As his quotations from Scripture appear to be made from the Peshitta, he probably wrote the homilies before he embarked upon the Philoxenian version. There are also extant portions of commentaries on the Gospels which he composed. Many of his letters survive, and at least two have been edited. Several of his writings were translated into Arabic and Ethiopic.

PHILTRE (Lat. philtre, from Gr. φιλτρον, φιλειν, to love), a drug or other medicinal drink supposed to have the magical property of exciting love.

PHINEUS, in Greek legend, son of Agenor, the blind king of Salmydessus on the coast of Thrace. He was skilled in the art of navigation, and Apollo had bestowed upon him the gift of prophecy. His blindness was a punishment from the gods for his having revealed the counsels of Zeus to mortals, or for his treatment of his sons by his first wife Cleopatra. His second wife having accused her stepsons of dishonourable proposals, Phineus put out their eyes, or exposed them to the wild beasts, or buried them in the ground up to their waists and ordered them to be scourg'd. Zeus offered him the choice of death or blindness. Phineus chose the latter, whereupon Helios (the sun-god), offended at the slight thus put upon him, sent the Harpies to torment him. In another story, the Argonauts (amongst whom were Calais and Zetes, the brothers of Cleopatra), on their arrival in Thrace found the sons of Phineus living in the island and the king dead. The island was given to them by the Libyans, who refused, and a fight took place in which he was slain by heracles, who freed Cleopatra (who had been thrown into prison) and her sons, and reinstated them as rulers of the kingdom. Tragedies on the subject of Phineus were written by Aeschylus and Sophocles. These would directly appeal to an Athenian audience, Phineus's first wife having been the daughter of Orithya (daughter of Ezechthas, king of Athens), who had been carried off by Boreas to his home in Thrace. The punishment of Phineus would naturally be regarded as a just retribution for the insult put upon a princess of the royal house of Athens.

Apollodoros i. 9, 21, iii. 15, 3; Sophocles, Antigone, 966, with Jebb's notes; Diod. Sic. iv. 43, 44; Servius on Aeneid iii. 209; Schol. on Apollonius Rhodius ii. 178.

PHIPS, or Purps, Sir William (1651-1695), colonial governor of Massachusetts, was born on the 2d of February 1651, at Woolwich, Maine, near the mouth of the Kennebec river. He was a shepherd until he was eighteen, and then a ship carpenter's apprentice for four years; worked at his trade in Boston for a year, at this time learning to read and write; and with his wife's property established a ship-yard on the Sheepscot river in Maine, and soon abandoned it because of Indian disorders. In 1684-1686, with a commission from the British Crown, he searched vainly for a wrecked Spanish treasure ship of which he had heard while on a voyage to the Bahamas; he found this vessel in 1687, and from it recovered £300,000. Of this amount much went to the duke of Albermarle, who had fitted out the second expedition. Phips received £16,000 as his share, was knighted by James II., and was appointed sheriff of New England under Sir Edmund Andros. Poorly educated and ignorant of law, Phips could accomplish little, and returned to England. In 1689 he returned to Massachusetts, found a revolutionary government in control, and at once entered into the life of the colony. He joined the North Church (Cotton Mather's) at Boston, and was soon appointed by the Governor of Massachusetts as an envoy against the French in Canada, which sailed in April 1690 and destroyed Port Royal. A much larger expedition led by Phips in July against Quebec and Montreal ended disastrously. Phips generously bought at their par value, in order to give them credit in the colony, many of the colony's bills issued to pay for the expedition. In the winter of 1690 he returned to England, vainly sought aid for another expedition against Canada, and urged, with Increase Mather, the colonial agent, a restoration of the colony's charter, annulled during the reign of Charles II. The Crown, at the suggestion of Mather, appointed him the first royal governor under the new charter. On reaching Boston in May 1692, Phips found the colony in a very disordered condition, and though honest, persevering and indisposed to exalt his prerogative at the expense of the people, he was unfitted for the difficult position. He appointed a special commission to try the witchcraft cases, but did nothing to stop the witchcraft mania, and suspended the sittings of the court only after great atrocities had been committed. In defending the frontier he displayed great energy, but his policy of building forts was expensive and therefore unpopular. Having the manners of a 17th-century sea captain, he became involved in many quarrels, and engaged in a bitter controversy with Governor Benjamin Fletcher of New York. Numerous complaints to the home government resulted in his being summoned to England to answer charges. While in London awaiting trial, he died on the 18th of February 1695.

PHLEBITIS (from Gr. φλεβειν, a vein), inflammation of a vein. When a vein is inflamed the blood in it is apt to form a clot, or thrombus, which, if loosened and displaced from its original position, may be carried as an embolus towards the heart and there be arrested; or it may pass through the cavities of the heart into the lungs, there to lodge and to give rise to alarming symptoms. If the thrombus is formed in the inflamed vein of a pile it may pass as an embolus (see Haemorrhoids) into the liver. If an embolus is carried through the left side of the heart it may enter the large vessels at the root of the neck and reach the brain, giving rise to serious cerebral disturbance or...
to a fatal paralysis. The thrombus may be formed in gout and rheumatism, or in consequence of stagnation of the blood-currant due to slowing of the circulation in various wasting diseases. When a thrombus forms, absolute rest in the recumbent posture is to be strictly enjoined; the great danger is the displacement of the clot. An inflamed and clotted vein, if near the surface, causes an elongated, dusky elevation beneath the skin, where the vein may be felt as a hard cord, the size, perhaps, of a cedar pencil, or a pen-holder. Its course is marked by great tenderness, and the tissue which was drained by the branches of that vein are livid from congestion, and perhaps boggy and pitting with oedema. If, as often happens, the inflamed vein is one of those running conspicuously upwards from the foot—a saphenous vein (αγηί δικτα)—the patient should be placed in bed with the limb secured on a splint in order to protect it from any rough movement. Should the clot become detached, it might give rise to sudden and alarming faintness possibly even to a fatal syncope. Thus, there is always grave risk with an inflamed and clotted vein, and modern surgery shows that the safest course is, when practicable, to place the limb on the bed, then to excise the vein upon the heart-side of the clotted piece and to remove the latter by dissection. When, as sometimes happens, the clot is invaded by septic organisms it is particularly liable to become disintegrated, and if parts of it are carried to various regions of the body they may there give rise to the formation of secondary abscesses. In the ordinary treatment of phlebitis, in addition to the insistence on perfect rest and quiet, fomentations may be applied locally, the limb being kept raised. Massage must not be employed so long as there is any risk of a clot being detached.

PHLEGON, of Tralles in Asia Minor, Greek writer and freedman of the emperor Hadrian, flourished in the 2nd century A.D. His chief work was the Olympiads, an historical compendium in sixteen books, from the 1st down to the 229th Olympiad (776 B.C. to A.D. 237), of which several chapters are preserved in Photius and Syncellus. Two small works by him are extant: On Marvels, containing some ridiculous stories about ghosts, prophecies and monstrous births, but instructive as regards ancient superstitions; On Long-lived Persons, a list of Italians who had passed the age of 100, taken from the Roman censuses. Other works ascribed to Phleon by Suidas are a description of Sicily, a work on the Roman festivals in three books, and a topography of Rome.

PHLOLOGIN, a mineral belonging to the group of micas (q.v.). It is a magnesium mica, differing from biotite in containing only a little iron; the chemical formula is [H,K(MgF)]Mg[Al(SiO3)]2. It crystallizes in the monoclinic system, but the crystals are roughly developed. There is a perfect cleavage parallel to the basal plane; the cleavage flakes are not quite so elastic as those of muscovite. Sometimes it is quite colourless and transparent, but usually of a characteristic yellowish-brown colour; and often with a silvery lustre on the cleavage surfaces, hence the trade name silver amber mica for some varieties. The name phlogopite is from Gr. φλόγος, fiery-looking, and inmica, being sometimes brownish red and coppery in appearance. The hardness is 2½–3, and the specific gravity 2·78–2·85. The optic axial plane is parallel to the plane of symmetry and the axial angle ω°–10°. Phlogopite occurs chiefly as scales and plates embedded in crystalline limestones of the Archean formation. The mica mined in Canada and Ceylon is mainly phlogopite, and is largely used as an insulator for electrical purposes. In Canada it occurs withapatite in pyroxene rocks which are intrusive in Laurentian gneisses and crystalline limestones, the principal mining district being in the Ottawa county in Quebec and near Burgess in Lanark county, Ontario. In Ceylon, the mineral forms irregular veins, rarely exceeding one or two feet in width, traversing granite, especially near the contact of this rock with crystalline limestone.

PHLOX (Nat. Ord. Polemoniaceae), a genus of about 30 species, mostly perennials having plants of great beauty, natives of North America (one occurs in Siberia), with entire, usually opposite, leaves and showy flowers generally in termina clusters. Each flower has a tubular calyx with five lobes, and a salver shaped corolla with a long slender tube and a flat limb. The five stamens are given off from the tube of the corolla at different heights and do not protrude beyond it. The ovary is three- celled with one to two ovules in each cell; it ripens into a three-valved capsule. Many of the species and varieties are tall herbs yielding a wealth of bloom throughout the summer and early autumn. These require a deep, rich, and rather heavy loam, and a cool, moist position to flourish.

The dwarf perennial species and varieties, the "moss pinks" of gardens, are charming plants for the rockery and as edging to beds and borders. They are trailing and tufted in habit, the branches rooting at the nodes. They succeed in poorer soil, and drier situations than the tall kinds. Seed is seldom produced. Propagation is effected by cuttings in July and early August, placed in a cold frame, and by division of the plants, which should be lifted carefully, and cut into rooted portions as required. The tufted kinds decay in patches in winter if the situation is moist and the weather mild and wet.

Phlox Drummondi and its numerous varieties are half-hardy annuals in Britain. It is a small-growing hairy plant, flowering profusely during the summer months. For early flowering it should be sown in heat in March and April and transferred out of doors in June. It succeeds if sown out of doors in April, but the flowering season is later and shorter.

The tall-growing border phloxes are divided into early and late flowering kinds respectively, the former derived mainly from P. glaberrima and P. suifruticosus, and the latter from P. maculata and P. paniculata. The salver-shaped flowers with cylindrical tubes range from pure white to almost bright scarlet; in colour, passing through shades of pink, purple, magenta lilac, mauve and salmon. New varieties are obtained by the selection of seedlings. Owing to the frequent introduction of new kinds, the reader is referred to the current lists published by growers and nurseries. The "moss pinks," P. subuluta and its varieties, are all worthy of a place in the alpine garden.

The varieties are relatively few. The following list includes nearly all the best kinds:

- P. subulata, pink with dark centre; Aldboroughensis, rose; annulata, bluish white, ringed with purple; atroilicata, deep lilac; atropurpurea purple-rose and crimson; Brightness, bright rose with scarlet eye; Holiday, clear rose; hay, Lilac rose; Wilson, mauve; grandiflora, pink, crimson blotch; Little Dot, white, blue centre; Nolan, pure white; Vivid, rose, carmine centre; all these are about 4 in. high. P. divaricata, lavender, height 1 ft.; P. ovata, rose, 1 ft.; P. repens, rose, 6 in.; and P. amoena, rose, 9 in., are also charming alpines.

P. Drummondii varieties come true from seed, but are usually sown in mixture.

PHOCAEA (mod. Fokha or Fokha) an ancient city on the western coast of Asia Minor, famous as the mother city of Marseilles. It was the most northern of the Ionian cities, and was situated on the coast of the peninsula which separates the gulf of Cyme, occupied by Acolian settlers, from the Hermaean Gulf, on which stood Smyrna and Clazomenae.1 Its position between two good harbours, Naustathmus and Lampeter (Livy xxvii. 31), led the inhabitants to devote themselves to maritime pursuits. According to Herodotus the Phocaeans were the first of all the Greeks to undertake distant voyages, and made known the coast of the Adriatic, Tyrrenia and Spain. As a result of this knowledge they settled in many foreign lands, and used them to emigrate in a body to his dominions, and, on their declining, presented them with a large sum of money. This they employed in constructing a strong wall around their city, a defence which stood them in good stead when Ionia was attacked by Cyrus in 546. Eventually they determined to seek a new home in the west, where they already had flourishing colonies, e.g. 1

1 It was said to have been founded by a band of emigrants from Phocis, under the guidance of two Athenian leaders, named Philogenes and Damon, but it joined the Ionian confederacy by accepting the government of Athenian rulers of the house of Codrus.
PHOCAS—PHOCIS

Alalia in Corsica and Massilia (mod. Marseilles). A large part of the emigrants proceeded only as far as Chios, returned to Phocaea, and submitted to the Persian yoke.

Phocaea continued to exist under the Persian government, but greatly reduced in population and commerce. Though it joined in the Ionian revolt against Persia in 500 it was able to send only three ships to the combined fleet which fought at Lade. But a Phocaean took the supreme command. It never again played a prominent part in Ionian history, and is rarely mentioned. In the time of Timur Fuhaj was a fortress of Sarukhan, but had been previously in Genoese hands. The ruins still visible on the site bear the name of Palaea Fokia, but they are of little interest. The modern town in the immediate neighbourhood, still known as Fokia, was founded by the Genoese in 1421 on account of the rich alum mines in the neighbourhood. It has a fair natural harbour, which is the nearest outlet of the rich district of Menemen. About 1856, while the Gediz Chai was throwing its silt unchecked into the Gulf of Smyrna and gradually filling the navigable channel, there was talk of reviving Fokia as a new port for Smyrna, and connecting it with the Cassaba railway. But, in deference to Smyrnians protests, a new estuary was cut for the Gediz. Fokia has acquired local importance however as a port of call for coasting steamers, and it is used to some degree as a summer residence by Smyrnians.

(D. G. H.)

PHOCAS, East Roman emperor (602-610), was a Cappadocian of humble origin. He was still but a centurion when chosen by the army of the Danube to lead it against Constantinople. A revolt within the city soon afterwards resulted in the abdication of the reigning emperor Maurice, and in the elevation of Phocas to the throne, which seems to have been accomplished by one of the circus factions against the wish of the troops. Phocas proved entirely incapable of governing the empire. He consented to pay an increased tribute to the Avars and allowed the Persians, who had declared war in 604 under Chosroes II., to overrun the Asiatic provinces and to penetrate to the Bosphorus. When the central emperor had been dethroned against him, Phocas was deserted by the starving populace of Constantinople, and deposed with scarcely a struggle (610). He died in the same year on the scaffold.

PHOCION, Athenian statesman and general, was born about 402 B.C., the son of a small manufacturer. He became a pupil of Plato and in later life was a close friend of Xenocrates. This academic training let its mark upon him, but he was as a soldier rather than as a philosopher that he first came into notice. Under Chabrias he distinguished himself in the great sea-fight of Naxos (376), and in the subsequent campaigns loyally supported his chief. He won the confidence of the allies by his justice and integrity. In 351-349 he entered the Persian service and helped to subdue a rebellion in Cyprus. Henceforward he always held a prominent position in Athens, and although he never canvassed he was elected general forty-five times in all. In politics he is known chiefly as the consistent opponent of the anti-Macedonian firebrands, headed by Demostenes, Lycurgus and Hyperides, whose fervent eloquence he endeavoured to stum by recounting the plain facts of Athens's military and financial weakness and her need of peace, even when the arms of Athens seemed to prosper most. But although he won the respect of his audience, his advice was frequently discarded. Yet his influence was felt at the trial of Aeschines in 343, whom he helped to defend, and after the disaster of Chaeroneia (338), when he secured very lenient terms from Philip. He also rendered good service in the field: in 348 he saved the force operating against the pho-Macedonian tyrants in Euboea by the brilliant victory of Tymannae. Under the Macedonian predominance his reputation steadily increased.

1 Diodorus's statement that Phocion was 75 at his death (i.e. that he became general at 30 and was elected 45 years in succession) would give 394-393 as the date of birth; but he must have been quite 25 as second-in-command at Naxos (376).

2 The chronology is uncertain; the dates given for this period are Beloch's Griechische Geschichte.

Though by no means inclined to truckle to the Macedonians, as is shown by his protection of the refugee Harpalus and his spirited campaign in defence of Attica in 332, he won the confidence of the conquerors, and in the restricted democracy which Antipater enforced he became the virtual ruler of Athens. Old age, however, was telling on him; when Polyperchon by his proclamation of "freedom" raised a new crisis in 318, Phocion's dilatoriness was interpreted as active treason on Cassander's behalf, and the people, incited by the restored democrats, deposed him from office. Phocion fled to Polyperchon, but was sent back by the latter to be tried at Athens. The assembly, containing numerous slaves and all the city mob, shouted Phocion down and condemned him to death unheard. Not long after, the Athenians decreed a public burial and a statue in his honour.

Phocion's character and policy were throughout inspired by his philosophic training, which best explains his remarkable purity of character and his prudent councils. To the same influence we may ascribe his reserve and his reluctance to co-operate heartily either with the people or with the Macedonian conquerors who put their trust in him; a greater spirit of energy and enterprise might have made him the saviour of his country. Phocion remained famous in antiquity for the pithy sayings with which he used to parry the eloquence of his opponents. Demosthenes called him "the chopper of my periods."

Plutarch (Life of Phocion) draws much good information from Philochorus and Duris (who reproduces Hieronymus of Cardia; his numerous anecdotes are repeated in other works of his and in Aelian (Var. Hist.)). Diodorus (xvi.-xviii.) is likewise based on Duris. See Holm. Gk. Hist. vol. iii. (Eng. trans., London, 1896).

(PHOCIS, an ancient district of central Greece (now a department, pop. 62,246), about 625 sq. m. in area, bounded on the W. by Ozolian Locros and Doris, on the N. by Opuntian Locris, on the E. by Boeotia, and on the S. by the Corinthian Gulf. The massive ridge of Parnassus (8068 ft.), which traverses the heart of the country, divides it into two distinct portions. Between this central barrier and the northern frontier range of Chemis (3000 ft.) is the narrow but fertile valley of the Cephissus, along which most of the Phocian townships were scattered. Under the southern slope of Parnassus were sitiuated townships of Crinis, Thermodaia, and Chosroes; by Mt Cirphis, an offshoot from the main range. Being neither rich in material resources nor well placed for commercial enterprise, Phocis was mainly pastoral. No large cities grew up within its territory, and its chief places were mainly of strategic importance.

The early history of Phocis remains quite obscure. From the scanty notices of Greek legend it may be gathered that an influx of tribes from the north contributed largely to its population, which was reckoned as Aeolic. It is probable that the country was originally of greater extent, for there was a tradition that the Phocians once owned a strip of land round Daphnis on the sea opposite Euboia, and carried their frontier to Thermopylae; in addition, in early days they controlled the great sanctuary of Delphi. The restriction of their territory was due to the hostility of their neighbours of Boeotia and Thessaly, the latter of whom in the 6th century even carried their raids into the Cephissus valley. Moreover the Dorian population of the territory, as was certainly to be expected, required time and trouble to establish its independence and at about 500 B.C. induced a coalition of Greek states to proclaim a "Sacred War," and free the oracle from Phocian supervision. Thus their influence at Delphi was restricted to the possession of two votes in the Amphictyonic Council.

During the Persian invasion of 480 the Phocians at first joined in the national defence, but by their irreligious conduct at Thermopylae lost that position for the Greeks; in the campaign of Plataea they were enrolled on the Persian side. In 475 an attempt to extend their influence to the head waters of the Cephissus in the territory of Doris brought a Spartan army into Phocis in defence of the "metropolis of the Dorians." A similar enterprise against Delphi in 448 was again frustrated by Sparta, but not long afterwards the Phocians recaptured the sanctuary with the help of the Athenians, with whom they
PHOCYLIDES—PHOENICIA

had entered into alliance in 454. The subsequent decline of Athenian power had the effect of weakening this new connection; at the time of the Peloponnesian War Phocis was nominally an ally and dependent of Sparta, and had lost control of Delphi.

In the 4th century Phocis was constantly endangered by its Boeotian neighbours. After helping the Spartans to invade Boeotia during the Corinthian War (395-94), the Phocians were placed on the defensive. They received assistance from Sparta in 380, but were afterwards compelled to submit to the growing power of Thebes. The Phocian levy took part in Epaminondas' inroads into Peloponnesus, except in the final campaign of Mantinea (362-6), from which their contingent was withheld. In return for this negligence the Thebans fastened a religious quarrel upon their neighbours, and secured a penal decree against them from the Amphictyonic synod (356). The Phocians, led by two capable generals, Philomelus and Onomarchus, replied by seizing Delphi and using its riches to hire a mercenary army. With the help of these troops the Phocian League at first carried the war into Boeotia and Thessaly, and thence driven out of the latter country by Philip of Macedon, maintained itself for ten years, until the exhaustion of the temple treasures and the treachery of its leaders placed it at Philip's mercy. The conditions which he imposed—the obligation to restore the temple funds, and the dispersion of the population into open villages—were soon disregarded. In 339 the Phocians began to rebuild their cities; in the following year they fought against Philip at Chaeronea. Again in 323 they took part in the Lamian War against Antipater, and in 279 helped to defend Thermopylae against the Gauls.

Henceforth little more is heard of Phocis. During the 3rd century it passed into the power of Macedonia and of the Aetolian League, to which it belonged in 166 it was definitely annexed. Under the dominion of the Roman republic its national league was dissolved, but the identity of the nation was preserved by Augustus, who restored the votes in the Delphic Amphictyony which it had lost in 346 and enrolled it in the new Achaean synod. The Phocian League is last heard of under Trajan.

(M. O. B. C.)

PHOCYLIDES, Greek gnomic poet of Miletus, contemporary of Theognis, was born about 560 B.C. A few fragments of his "maxims" have been preserved (chiefly in the Florilegium of Stobaeus), in which he expresses his contempt for the pomp and vanities of rank and wealth, and sets forth in simple language his ideas of honour, justice and wisdom. A complete didactic poem (230 hexameters) called Πολύμα ανθοφόροιν or γυμνάσια, bearing the name of Phocylides, is now considered to be the work of an Alexandrian Christian of Jewish origin who lived between 170 B.C. and A.D. 50. The Jewish element is shown in verbal agreement with passages of the Old Testament (especially the book of Sirach); the Christian by the doctrine of the immortality of the soul and the resurrection of the body. Some Jewish authorities, however, maintain that there are in reality no traces of Christian doctrine to be found in the poem, and that the author was a Jew. The poem was first printed at Venice in 1495, and was a favourite school textbook during the Reformation period.

See fragments and the spurious poem in T. Berg, Poetae lyrici graeci, ii. (4th ed., 1882); J. Bernays Über das Phokidische Gedicht (1868); Phocylides, Poem of Admonition, with introduction and commentary by J. B. Fenning, and translation by H. D. Goodwin (Andover, Mass., 1879); F. Susembii, Geschichte der griechischen Literatur in der Alexandrinerszeit (1892), ii. 624; F. Krauss' (s.v. "Phocylides") in The Jewish Encyclopedia and E. Schürer, History of the Jewish People, iv. 2, vol. iii, 313-316; Eng. trans., 1886, where full bibliographies are given. There is an English verse translation by W. Hewett (Watford, 1840), The Perspicus Poem of Phocylides.

PHOEBE, in astronomy, the ninth satellite of Saturn in order of discovery, or the tenth and outermost now known in the order of the discovery. It was discovered by W. H. Pickering in 1899 by photographs of the stars surrounding Saturn. It is remarkable in that its motion around the planet is retrograde.

(See SATURN.)

PHOEBUS (Gr. for "bright," "pure"), a common epithet of Apollo (q.v.). Artemis in like manner is called Phoebe, and in the Latin poets and their modern followers Phoebus and Phoebre are often used simply for the sun and moon respectively.

PHOENICIA, in ancient geography, the name given to that part of the seaboard of Syria which extends from the Eleutherus (Nahr el-Kebir) in the north to Mt Carmel in the south, a distance of rather more than two degrees of latitude. These limits, however, were exceeded at various times; thus, north of the Eleutherus lay Arados and Marathus, and south of Carmel the border sometimes included Dor and even Joppa. Formed partly by alluvium carried down by perennial streams from the mountains of Lebanon and Galilee, and fringed by great sand-dunes which the sea throws up, Phoenicia is covered with a rich and fertile soil. It is only at the mouth of the Eleutherus and at Acre (Akka) that the strip of coast-land widens out into plains of any size; there is a certain amount of open country behind Beirut; but for the most part the mountains, pierced by deep river-valleys, approach to within a few miles of the coast, or even right down to the sea, as at Ras-en-Nakura (Saca Tyriorum, Jos. Bell. Jud. ii. 10, 2) and Ras el-Abiad (Pliny's Promonturium Album), where a passage had to be cut in the rock for the caravan road which from time immemorial traversed this narrow belt of lowland. From the flanks of Lebanon, especially from the heights which lie to the north of the Kasimlyeh or Kasimiyeh (Litany) River, the traveller looks down upon some of the finest landscapes in the world; in general features the scenery is not unlike that of the Italian Riviera, but surpasses it in grandeur and a peculiar depth of colouring.

With regard to natural products the country has few worth mentioning. The principal crops are flax, grain and fruit; the Lebanon cedars have an almost legendary value; and in quantity; traces of amber-digging have been discovered on the coast; and the purple shell (murex trunculus and brandaris) is still plentiful. The harbours which played so important a part in antiquity are nearly all silted up, and, with the exception of Beirut, afford no safe anchorage for the large vessels of modern times. A few bays, facing towards the north, break the coast-line, and small rocky islands are dotted here and there just off the shore. Sidon, Tyre and Arados, though now connected with the mainland, were built originally upon islands; the Phoenicians preferred such sites, because they were convenient for shipping and easily defended against attack.

The chief towns of ancient Phoenicia, as we know them from the Amarna tablets (15th century B.C.) and from Egyptian, Assyrian and the Old Testament documents, were the following: Aradus (now Acre or Akka, Jud. i. 24), Achzib (now ez-Zib, ibid.), Ahlab (in Assyrian Mahalliba, ibid.)—three towns on the coast south of Tyre, Kando (Josh. xix. 28), Tyre (Phoen. Shi or Shi), Zarephath (now Sarafand), Aradus (now Safad), Berytus (Biruta in Egyptian, Biruna in the Amarna tablets, now Beirut), Byblos (in Phoen. and Bevr. Gebal, now Jbeil), Arka, 80 m. north of Sidon (Gen. x. 17, now Arka), Sin (Assyr. Sinna, ibid.), and Hippos, 18 m. north of Hippos, now Arwad, Send, Gen. x. 18; Ezek. xxvii. 11, the most northerly of the great Phoenician towns, and always famous as a maritime state.

Race and Language.—The Phoenicians were an early offshoot from the Semitic stock, and belonged to the Canaanite branch of it. Curiously enough in Gen. x. Sidon, the "first-born" of the Canaanite, is classed among the descendants of Ham; but the table of nations in Gen. x. is not arranged upon strict ethnographic principles; perhaps religious antagonism induced the Hebrews to assign to the Canaanites an ancestry different from their own; at any rate the close connexion which existed from an early date between the Phoenicians and the Egyptians may have suggested the idea that both peoples belonged to the same race. The Phoenicians themselves retained some memory of having migrated from older seats on an eastern sea; Herodotus (i. 1; vii. 89) calls it the "red sea," meaning probably the...
PHOENICIA

Persian Gulf; the tradition, therefore, seems to show that the Phoenicians believed that their ancestors came originally from Babylonia. By settling along the Syrian coast they developed a strong feeling of love for the sea, and advanced on different lines from the other Canaanites who occupied the interior. They called themselves Canaanites and their land Canaan; such is their name in the Amarna tablets, Kinahhi and Kinahni; and with this agrees the statement assigned to Hecataeus (Fr. hist. gr. i. 17) that Phoenicia was formerly called Χρόα, a name which Philo of Byblos adopts into his mythology by making Chna who was afterwards called Phoinix the eponym of the Phoenicians (Fr. hist. gr. iii. 560). In the reign of Antiochus IV. and his successors the coins of Laodicea of Libanus bear the legend “Of Laodicea which is in Canaan”; 1 the Old Testament also sometimes denotes Phoenicia and Phoenicians by “Canaan” and “Canaanites” (Isa. xxiii. 11; Obad. 20; Zeph. i. 11), though the latter names generally have a more extended sense. But “Sidonians” is the usual designation both in the Old Testament and in the Assyrian monuments (Sidduna); and even at the time of Tyre’s greatest ascendency we read of Sidonians and not Tyrians in the Old Testament and in Homer; thus Ethbaal king of Tyre (Jos. Ant. viii. 13, 2) is called king of the Sidonians in 1 Kings xvi. 31. In the Homeric poems we meet with Phoinikes (Od. iv. 62, vi. 290, Od. ii. 285, II. vi. 972), Phoinikis (Od. ii. 298 seq.), and both terms together (Od. iv. 83 seq., II. xxiii. 743 seq.) and the Phoenicians themselves used Sidonians as a general name; thus in the oldest Phoenician inscription known (CIS. i. 5 = NSI., No. 11), Hiram II. king of Tyre in the 8th century is styled “king of the Sidonians.” But among the Greeks “Phoenicians” was the name most in use, Φόινικες (plur. of Φόινιξ) for the people and Φωινική for the land (cf. Phoenix). The former was probably the older word, and may be traced to φωινίζω = “blood-red”; the Canaanite sailors were spoken of as the “red men” on account of their sunburnt skin; then the land from which they came was called after them; and then probably the original connexion between Φωινίξ and Φωινική was forgotten, and new forms and meanings were invented. Thus φωινίξ came to mean a “date-palm,” but the date-palm is not in the least characteristic of Phoenicia, and can hardly grow there; φωινική in this sense has no connexion with the original meaning of Phoenician. A derivation has been sought elsewhere, and the Egyptian Fenh proposed as the origin of the name; but the Egyptian Fenh was apparently used by the Asiatic barbarians as a general word, without any connexion to the Phoenicians (W. M. Müller, Asien u. Europa, p. 208 seq.). The Lat. Phoenix is of course merely an adaptation of the Greek form.

Language.—Inscriptions, coins, topographical names preserved by Greek and Latin writers, names of persons and the Punic passages in the Poenitut of Plautus, all show conclusively that the Phoenician language belonged to the North-Semitic group, and to that sub-group of it which is called the Canaanite and includes Hebrew and the dialect of Moab. A comparison between Phoenician and Hebrew reveals close resemblances both in grammatical forms and in vocabulary; in some respects older features have been preserved in Phoenician. The Phoenician has also some agglutinative features, distinct; in other words poetic or rare or late in Hebrew are common in Phoenician. Hence we may conclude that the two languages developed independently from a common ancestor, which can be no other than the ancient Canaanite which has left us some monuments; the Canaanite glosses to the Amarna tablets (written in Babylonian). But in forming an estimate of the Phoenician language it must be remembered that our material is scanty and limited in range; the Phoenician literature is so vast and varied that one cannot treat of the Phoenician language without infinite labour; moreover, with the exception (CIS. i. 5), almost all the inscriptions are subsequent to the 6th century B.C.; the majority belong to the 4th century and later, by which time the language must have undergone a certain amount of decay. 3 Indirectly, however, the Phoenicians rendered one great service to literature; they took a large share in the development and diffusion of the alphabet which forms the foundation of Greek (Herod. v. 58) and of all European writing. The Phoenician letters in their earlier types are practically identical with those used by the Hebrews (e.g. the Siloam inscr. NSI. No. 2), the Moabites (the Mesha-stone, ibid. No. 1), and the Arameans of north Syria (e.g. the Zenjirli inscr. ibid. Nos. 61-63). They passed through various modifications in the course of time; after leaving the mother country the script acquires a more cursive, flowing style on the stones from Cyprus and Attica; the tendency of which is strongly marked at the Punic stage; until in the neo-Punic, from the destruction of Carthage (146 B.C.) to the 1st century A.D., both the writing and the language reached their most degenerate form. As a rustic dialect the language lasted on in North Africa till the 16th century. A.D. In his sermons St. Augustine frequently quotes Punic words.

History.—The Phoenicians, in imitation of the Egyptians, claimed that their oldest cities had been founded by the gods themselves, and that their race could boast an antiquity of 30,000 years (Africanus in Synecclus, p. 31). Herodotus quotes (ii. 44) a more moderate tradition which placed the foundation of Tyre 2300 years before his time, i.e., c. 2750 B.C. According to Justin (xviii. 3) the Phoenicians, who had long been settled on the coast and occupied Sidon, founded Tyre in the year before the fall of Troy; possibly the date 1108 B.C., given by Menander of Ephesus (in Jos. Ant. viii. 3, i and c. Ap. i. 18) as that from which the era of Tyre begins, may refer to the epoch which Justin mentions. Little certainty, however, can be allowed to these traditional chronologies. It is probable that in remote ages Babylonia exercised a considerable influence upon Syria and its coast towns; but Mr. L. W. King has shown that the tradition, which was supposed to connect Sargon I. (c. 3500 B.C.) with the western land and sea, has been misunderstood; it was the sea in the east, i.e. the Persian Gulf, which Sargon crossed (Chronicles concerning Early Bab. Kings, vol. i. ch. 2, 1907).

The extension of the Egyptian empire in the direction of Asia began about 1800 B.C. under Amosis (Aahmes, Amaasis) I., the founder of the XVIIIth Dynasty, who carried his arms into Syria, and conquered at least Palestine and Phoenicia, the latter being the country called Da-hi on the Egyptian monuments (Müller, As. u. Eur. p. 181). Whether the campaign of Thothmes (Tethmosis) I. to the Euphrates produced any lasting results is doubtful; it was Thothmes III. (1503-1449) who repeated and consolidated the earlier conquest, and established Egyptian suzerainty over all the petty states of Syria and Phoenicia (see Egypt: History, I.). For the geography and civilization of Canaan about 1400 B.C. we have valuable evidence in the Egyptian papyrus Anastasi I., which mentions Keupna (Gubna, Gebal-Bylus) the holy city, and continues: “Come then to Berytus, to Sidon, to Sarepta. Where is the ford of Nat-ana (Nahr el-Asimiyeh, or a town)? Where is Eitu (Usu, Palaeocytherus)? Another city on the sea is called a haven, D’ar (Tyre) is its name, water is carried to it in boats; it is richer in fish than any other. But the finest information of all is found in the Egyptian reports. In the 17th and 18th centuries B.C. comes from the Amarna tablets, among which are many letters from the subject princes and the Egyptian governors of Phoenicia to the Pharaoh. 4 It was a time of much political disturbance. The Hittites (q.v.) were invading Syria; nomads from the desert supported the invasion; and many of the local chiefs were ready to seize the opportunity to throw off the yoke of Egypt. The towns of Phoenicia were

1 Cooke, North-Semitic Inscriptions (elsewhere abbreviated NSI.), No. 149 B. 8.
2 In this passage “Phoenicians” is a general name for carriers of commerce, not the inhabitants of a particular country. Similarly “Canaan” (CIS. i. 5) is a liturgical Semitic name in general. Elsewhere “Phoenicians” are merchants, kings, seamen, &c.; “Sidonians” are artists; to indicate nationality both names seem to be used indifferently, e.g. Od. xiii. 272, xiv. 288, xiv. 414.
4 A vocabulary is given in KAT. 1, 652 seq.; see further Böhl, Die Sprache d. Amarnabriefe (1909).

[For the Phoen. inscr. see Corpus inscriptionum semiticarum, pt. i., brought up to date provisionally by Répertoire d’épigraphie sémitique. A selection is published by Lidzbarski, Handbuch d. nordischen Epigraphik; 1898; Cooke, Textbook of North-Semitic Inscriptions and Translations, 1910.]
divided; Aradus, Simyra, Sidon supported the rebellion; Ribhabad, the vassal of Byblus, and Abi-melech, king of Tyre, held out for Egypt; but while all the towns made professions of fidelity, they were scheming for their own interests, and in the end Egypt lost them all except Byblus. The tablets which reveal this state of affairs are written in the language and script of Babylon, and thus show indirectly the extent to which Babylonian culture had penetrated Palestine and Phoenicia; at the same time they illustrate the closeness of the relations between the Canaanite towns and the dominant power of Egypt. After the reign of Amenophis IV. (1376-1366) that power collapsed altogether; but his successors attempted to recover it, and Ramses (Rameses) II. reconquered Phoenicia as far as Beirūt, and carved three tablets on the rock beside the Nahr el-Kebel to commemorate his victories; under the XIXth and XXIst Dynasties this seems to have remained the northern limit of the Egyptian Empire. But in the reign of Ramses III. (c. 1200) great changes began to occur owing to the invasion of Syria by peoples from Asia Minor and Europe, which ended in the establishment of the Philistines on the coast near Ashkelon. The successors of Ramses III. lost their hold over Canaan; the XXIst Dynasty no longer intervened in the affairs of Syria; but Sheshonk (Shishak), the founder of the XXIInd Dynasty, about 928 B.C. endeavoured to assert the ancient supremacy of Egypt (cf. Kings xiv. 25 sqq.), but his successes were not lasting, and, as we learn from the Old Testament, the power of Egypt became henceforward practically ineffective. Not until 606 did a Pharaoh (Necho) lead an Egyptian army so far north, and he was defeated by Nebuchadrezzar. During the period which elapsed before the rise of the Assyrian power in Syria the Phoenicians were left to themselves. This was the period of their development, and Tyre became the leading city of Phoenicia.

Between the withdrawal of the Egyptian rule in Syria and the western advance of Assyria there comes an interval during which the city-states of Phoenicia owned no suzerain. The history of this period is mainly a history of Tyre, which not only rose to a sort of hegemony among the Phoenician states, but founded colonies beyond the seas (below). From 970 to 772 B.C. the bare outline of events is supplied by extracts from two Hellenistic historians, Menander of Ephesus and Dios (largely dependent upon Menander), which have been preserved by Josephus, Ant. viii. 5, 3 and c. Ap. i. 17, 18. From the data given in these passages we learn that Hiram I., son of Abi-baal, reigned in Tyre from 970 to 936 B.C. He enlarged the island-town to the east, restored and enriched the temples, built new ones to Heracles (i.e. Melkarth or Melqarth) and Astarte, founded the feast of the awakening of Heracles in the month Peritius, and reduced the inhabitants of Utica to their allegiance. The Assyrian annals, moreover, allude to the connexion between Hiram and Solomon. Before this time, indeed, the Phoenicians had no doubt lived on friendly terms with the Israelites (cf. Judges v. 17; Gen. xlix. 13); but the two nations seem to have drawn closer in the time of Solomon. 2 Sam. v. 11, which brings David and Hiram together, probably antedates what happened in the following reign. For Solomon's palace and temple Hiram contributed cedar and fir trees as well as workmen, receiving in exchange large annual payments of oil and wine, supplies which Phoenicia must have drawn regularly from Israelite districts (1 Kings v. 9, 11; cf. Ezek. xxvii. 17; Ezr. iii. 7; Acts xii. 10; Jos. Ant. xiv. 10, 6); finally, in return for the gold which he furnished for the temple, Hiram received the grant of a territory in Galilee (Cabul, 1 Kings ix. 10-14). 3 This alliance between the two monarchs led to a joint expedition from Elainggeber on the Gulf of Akaba (strictly Aqaba) to Ophir (? on the east coast of Arabia, see Ophir) for purposes of trade. The list of Hiram's successors given by Josephus indicates frequent changes of dynasty until the time of Ithobal I. priest of Astarte, whose reign (887-855) marks a return to more settled rule. In contrast to Hiram I., king of Tyre, Ithobal or Ethbaal is styled in 1 Kings xvi. 31 "king of the Sidonians," i.e. of the Phoenicians, showing that in the interval the kings of Tyre had extended their rule over the other Phoenician cities. Under Ethbaal further expansion is recorded; Botrys north of Byblus and Aozà in North Africa are said to have been founded by him; the more famous Carthage owed its origin to the civil discord which followed the death of Metten I. (820), his next successor but one. According to tradition, Metten's son Pygmalion (830-773) slew the husband of his sister Elissa or Dido; whereupon she fled and founded Carthage (q.v.) in Libya (813; Justin xviii. 4-6). At this point Josephus' extracts from Manemer come to an end.

From the time of Ethbaal onwards the independence of Phoenicia was threatened by the advance of Assyria. So far back as 1100 B.C. Tiglath-pileser I. had invaded North Phoenicia, and in order to secure a harbour on the coast he occupied Arvad (Aradus); but no permanent occupation followed. In the 8th century, however, the systematic conquest of the west began. In 876 B.C. Assur-nazir-pal III. "washed his weapons in the great sea," and exacted tribute from the kings of Tyre, Sidon, Byblus and other cities, including Carthage (Keltinschr. Bibliothek, i. 109). The inscriptions of his son Shalmaneser II. mention the taking of tribute from the Tyrians and Sidonians in 846 and again in 840; the Byblians are included at the latter date, and among the kings defeated at Karkar in 854 or 853 was Metten-baal, king of the Arvadites (ibid. pp. 141, 143, 173). Thus Shalmaneser completed the conquests of his predecessor on the Phoenician coast, and established a supremacy which lasted for a hundred years and was acknowledged by occasional payments of tribute.

In 741 Tiglath-pileser III. mentions on his tribute-lists "Hiram of Tyre," and here for the first time a piece of native evidence becomes available. The earliest Phoenician inscription hitherto known (CIS. i. 5 = NSI. No. 11) is engraved upon the fragments of a bronze bowl dedicated by a certain governor of Qarth-hadasht (or Karti-Hadiasti, "New City," i.e. Citium), "servant of Hiram king of the Sidonians to Baal of Lebanon." It is to be noted that this Hiram II. was not only king of Tyre, as the Assyrian inscription calls him, but of Sidon too; and further, that by this time Tyre had established a colony in Cyprus (q.v.). In Tiglath-pileser's Philistine campaign of 734 B.C. Byblus and Aradus paid tribute, and an Assyrian chief officer (the Rab-shakeh) was sent to Tyre and extorted from the king, now Metten or Mattūn, the large sum of 150 talents of gold (K.B. ii. 23). For the period which follows a certain amount of information is furnished by Menander (in Jos. Ant. ix. 14, 2). Elauesus IX., in Assyrian Luli, who ruled under the name of Pylas, was king of Tyre, Sidon, and other cities at this time (c. 725-690), and at the beginning of his reign suffered from an invasion by Shalmaneser IV. or Salammsa (Jos.); this was probably the expedition against Hoshea of Samaria in 725; "the king of Assyria... overran all Phoenicia, but soon made peace with them all and returned back." In the reign of Sargon Phoenicia itself seems to have been left alone; but the inhabitants of Cition revolted, showing that the authority of Tyre in Cyprus had grown weak; and Sargon received the submission of seven Cyprian princes, and set up in Larissa (probably in 790) the triumphal stele now in the Berlin Museum (Schrader, Cuneif. Inschr. and O. T., 2nd ed., vol. ii. p. 87). But Elauesus, according to Menander, suppressed the revolt of Cition, and early in the reign of Sennacherib joined the league of Philiastia and Judah, which had considerable effect upon the cities of Phoenicia (above, Justin xviii. 3). In the Assyrian annals (Jos. c. Ap. 1. 18) the reference was probably to the falling of timber in Lebanon for Hiram's temple; Josephus then misunderstood this by 1 Kings v. 6.
in alliance with Egypt and Ethiopia, which aimed at throwing off the oppressive tyranny of Assyria; as usual, however, the city-states of Phoenicia could not combine even against a common foe, and several broke away from Tyre, so Menander tells us, and sided with Assyria. In the great campaign of 701 BC, Sennacherib came down upon the revolting provinces; he forced Luli, king of Sidon, to fly for refuge to Cyprus, took his chief cities, and set up Tubal'lu (Etbaal) as king, imposing a yearly tribute (KB. ii. 91). The blockade of Tyre by sea, significantly passed over in Sennacherib's inscription, is described by Menander. The island-city proved to be impregnable, but it was the only possession left of what had been the extensive kingdom of Elulaees. Sennacherib, however, so far accomplished his object as to break up the combination of Tyre and Sidon, which had grown into a powerful state.1 At Sidon the successor of Etbaal was Abd-malkah; in alliance with a Cilician chief he rebelled against Esarhaddon about the year 678, with disastrous consequences. Sidon was annihilated; Abd-malkah fell into the hands of Esarhaddon, who founded a new Sidon on the mainland, peopled it with foreigners, and called it after his own name. The old name, however, survived in popular usage; but the character of the city was changed, and till the time of Cyrus the kingdom of Elulaees (KB. ii. 145; KAT. ii. 88). Tyre also came in for its share of hardships. Elulaees was followed by Bala, who in 672 consented to join Tirhaka, the Ethiopian king of Egypt, in a rebellion against Assyria. Esarhaddon, on his way to Egypt for the second time, determined to deal out punishment; he blockaded Tyre, and raised earthworks on the shore and cut off the water-supply; but he did not capture the city itself. His monument found at Zenjirli represents the great king holding Baal of Tyre and Tirhaka of Egypt by cords fastened in their lips;2 there is no evidence, however, that he actually took either of them prisoner. Early in the reign of Assur-bani-pal Tyre was besieged again (668), but Assur-bani-pal succeeded no better than his predecessors. Nevertheless Baal submitted in the end, along with the princes of Gebal and Arvad, Manasseh of Judah, and the other Cannaante chiefs; in the island of Cyprus the Assyrians carried all before them (KB. ii. 149 seq., 169, 173). On his return from the Arabian campaign Assur-bani-pal severely punished the rebellious inhabitants of Ushu (Falateyru) and Akko, and transported the population of both countries to Assyria (ibid. 229). In Phoenicia, as elsewhere, Assyrian rule obscured nothing and left nothing behind it but a record of barbarous conquest and exploitation. An interesting sidelight is thrown upon this period by the list of the Thalassocrates in the Chronicles of Eusebius (p. 226, ed. Schoone), which places the 45 years of the sea-power of Phoenicia at a date which, with much probability, may be conjectured to lie between 709, when Cyprus submitted to Sargon, and 664, when Egypt threw off the rule of Assyria. If this dating is correct, and the Phoenician sea-power was at its height during these years, we can understand why Tyre gave so much trouble to the Assyrian kings.3

In the last crisis of the dying power of Assyria the Egyptians for a short time laid hands on Phoenicia; but after their defeat at the battle of Carchemish (605), the Chaldaean Babylonians became the masters of western Asia. Jeremiah's prophecy (605 BC) allusion (xxv. 22) in 604 to the approaching downfall of the kings of Tyre and Sidon and the coast-land beyond the sea, i.e. the Phoenician settlements on the Mediterranean, seems to imply that the Phoenician states recovered some measure of independence; if they did it cannot have lasted long. In 588 Apries (Pharaoh Hophra) made an attempt to displace the Chaldaean supremacy; he defeated Tyre and Sidon, and terrorized the other cities into submission (Herod. ii. 167; Diod. Sic. i. 68). Some of the Phoenician chiefs, among them Tyre-baal II, the new king of Tyre, while forced to yield to a change of masters, were bold enough to declare their hostility to the Babylonians. This state of affairs did not escape the vigilance of Nebuchadrezzar. After the fall of Jerusalem he marched upon Phoenicia; Apries withdrew his army, and the siege of Tyre began. For thirteen years the great merchant city held out (585-573; Jos. c. Ap. i. 21; cf. Ezek. xxvii. 1 seq.). Ezekiel says that Nebuchadrezzar and his host had no reward for their heavy service against Tyre, and the presumption is that the city capitulated on favourable terms; for Ithobal's reign ends with the close of the siege, and the royal family is subsequently found in Babylon. The king appointed by Nebuchadrezzar was Baal II. (574-564), after whose death a republic was formed under a single suffete or "judge" (shôdet). Josephus (loc. cit.) is again our authority for the changes of government which followed until the monarchy was revived. At length under Hiram III. Phoenicia passed from the Chaldaean to the Persians (538), and at the same time Amasis (Ajomis) II. of Egypt occupied Cyprus (Herod. ii. 182). There seems to have been no struggle; the great siege and the subsequent civil disorders which had exhausted Tyre, and Sidon took its place as the leading state. Abanu, who succeeded at this time, threw the effort for independence under Hanno the Great (538-521), the real founder of its fortunes; the old independence upon Tyre was changed for a mere relation of piety observed by the annual sending of delegates (theoupoli) to the festival of Melkarth (Arrian ii. 24; Polyb. xxxi. 20, 12). The disasters and humiliations which befall Tyre during this and the foregoing period might suggest that its prosperity had been seriously damaged. But Tyre always counted for more in commerce than in politics; and in the year 586, just before the great siege, Ezekiel draws a vivid picture (ch. xxvii.) of the extent and splendour of its commercial relations. Even when cut off from its possessions on the mainland the city itself was not captured; its seafaring trade went on; and though by degrees the colonies were lost, yet the ties of race and sentiment remained strong enough to bind the Phoenicians of the mother-country to their kindred beyond the seas.

Constitution.—At this point it is convenient to mention what little is known about the constitution of the Phoenician states. All the old writers (Hannibal, Plut. De Isra. 24, 31; Polyb. xxvii. 16) speak of them as bounded by the consent of the inhabitants, that is to say, the collection of the wealthier merchant families, who possessed great influence in public affairs; thus it was possible for war or peace to be decided at Tyre in the king's absence, or at Sidon against his will (Arrian ii. 15 and 16; Curtius i. 15). The priest of Melkarth at Tyre was the second man in the kingdom. Associated with the prince was a council of elders; such was the case at Gebal (Byblos) from the earliest times to the latest (Ezek. xxvii. 9); at Sidon this council consisted of 100 members (Diod. xvi. 45); perhaps also at Tyre. Inscriptions of the Satrap of Egypt (Satrap of Sidon) say that one of his predecessors was the king of the Phoenicians (Polyb. xxvii. 18; Xen. Anab. i. 3; Cic. de Leg. iv. 1. 15); what his position was it is difficult to say; in the colonies he may have been a district governor. During Nebuchadrezzar's time, as we have seen, a republic took the place of the monarch; in the 3rd century BC, an inscription from Tyre mentions a suffete (NSI. New Series, without adding more to our knowledge. Carthage, of course, was governed by two suffetes, and these officers are frequently named in connexion with the Carthaginian colonies (NSI. p. 115 seq.); but we must be careful not to draw the inference that Phoenicia was at this period possessed of a sufficient central bond was formed comprising Sidon, Tyre and Aradus, whose duty it was to contribute 300 triremes to the Persian fleet (Herod. vii. 89),

1 So the Babylonians, Canaanites (e.g. in the case of the Nephilim, Gen. vii. 2), Arabs, Greeks, traced the descent of heroic families to the gods. W. R. Smith, Kinship and Marriage, p. 206; S. I. Curtis's Primitive Sem. Rel. To-day (London, 1902), p. 112 seq.
2 An inscr. from Tyre may be read, "Abd ba'al chief of the Hundred." NSI. p. 129; Clermont-Ganneau, Recueil d'arch. or. ii. 294 seq.
3 The Neo-Babylonian period.

The Neo-Babylonian period

1 The above interpretation of Menander and the Assyrian evidence is based upon Ed. Meyer, Emyc. Bib. col. 3755. For a different explanation see Landau, Beitr. z. Altertumsk. d. Or. vol. i., followed by Winckler, Der Alte Orient, xxvi. 84 seq.; these scholars take Menander to refer to the later war of Esarhaddon and Assur-bani-pal against Baal of Tyre.

2 See the facsimile in Ausgrabungen in Sendschirli (Berlin, 1893), and p. 17 for the above interpretation of it.

to obtain much information. The native inscriptions, however, now become available, though most of them belong to the period which follows, and only a few have been discovered in Phoenicia itself. One of the earliest of these is the inscription of Byblos (CIG. No. 23, 17; NSI. No. 3), dating from the Persian period; it records a dedication made by Yehaw-milk, king of Gebal, and mentions the name of the king’s grandfather, Uri-milk, but the exact dates of their reign are not given.

When Alexander the Great entered Phoenicia after the battle of Issus (333 B.C.), the kings were absent with the Persian fleet in the Aegean; but the cities of Aradus, Byblos and Sidon welcomed him readily, the last-named showing a special zeal against Persia. The Tyrians also offered a submission, but refused to allow the conqueror to enter the city and sacrifice to the Tyrian Heracles. Alexander determined to make an example of the first who should offer opposition, and at once began the siege. It lasted seven months. With enormous toll the king drove out a mole from the mainland to the island and thus brought up his engines; ships from the other Phoenician towns and from Cyprus lent him their aid, and the town at length was forced in July 332; 8000 Tyrians were slain, 36,000 sold as slaves, and only a few notables, the king Azemilos, and the festal envoys from Carthage who had taken refuge in the sanctuary of Mekarth, were spared (Diod. xvii. 40-46). It is not unlikely that Zech. ix. 2-4 refers to this famous siege. For the time Tyre lost its political existence, while the foundation of Alexandria presently changed the lines of trade, and dealt a blow even more fatal to the Phoenician cities.

During the wars of Alexander’s successors Phoenicia changed hands several times between the Egyptian and the Syrian kings. Thus in 312 Tyre was captured from Antigonus by Ptolemy I., the ally of Seleucus; in 287 it passed into the dominion of Seleucus; in 275 again it was captured by Ptolemy II. Philadelphus, and began to live its own minutes as an autonomous city, the Tyre of Straton’s time (Herod. ii. 126-128; Diod. xviii. 49). The Tyrian coins of this period, stamped with native, Greek and Egyptian symbols, illustrate the traditional relations of the city and the range of her ambitions. A special interest attaches to these silver tetradrachms and didrachms (staters and half-staters), because they were used by the Jews for the payment of the temple tax as "shekels of the sanctuary" (NSI. p. 351).

Among the Phoenician states we know most about Sidon during this period. The kingship was continued for a long time. The story goes that Alexander raised to the throne a member of the royal family, Abdalonymus, who was living in obscure poverty and working as a gardener (Justin xi. 10; Curt. iv. 1; Diod. xvii. 47 wrongly connecting the story with Tyre). In 312 Ptolemy, then master of Phoenicia, appointed his general Philocles king of the Sidonians, and a decree in honour of this king has been found at Athens (Michel, No. 387, cf. 1267), but he cannot have reigned long. For at the end of the 4th and the beginning of the 3rd century we have evidence of a native dynasty in the important inscriptions of Tahbit, Eshmun-'azar and Bod-`ash'tart, and in the series of inscriptions (repeating the same text) discovered at Bostan esh-Shēbekh near Sidon (NSI. Nos. 4, 5, 6 and App. 1), the last-named texts imply that the first king of this dynasty was Eshmun-'azar; his son Tahbit succeeded him; then came Eshmun-'azar II., who died young, then Bod-`ash'tart, both of them grandsons of Eshmun-'azar I. With Bod-`ash'tart, so far as we know, the dynasty came to an end, say about 250 B.C.; and it is not unlikely that the Sidonians reckoned an era of independence from this event (NSI. p. 95 n.).

Of the other Phoenician cities something is known of the history of Aradus. Its era began in 259 B.C., when it probably became a republic or free city. While the rest of Phoenicia passed under the Persian monarch is always styled "king of kings." The interpretation of many details of the inscr. from Bostan esh-Shēbekh is still uncertain.
rule of Ptolemy II. and his successors between 281 and 197, Aradus remained in the kingdom of the Seleucids, who greatly feared the city and increased its privileges (Strabo xvi. 2, 14; Polyb. v. 68). But its subject-towns availed themselves of the political changes of the period to throw off their allegiance: Marathus from 278 B.C. issued to this effect a coinage bearing the heads of the Ptolemies, and later on Karne asserted its independence in the same way; but in the end the Aradians recovered their supremacy. Diodorus records a barbarous attempt made by the Aradians about 148 B.C. to have the city burned, which was frustrated by the pity and courage of an Aradian fisherman (xiii. 1). At last in the time of Tigranes, the Armenian holder of the kingdom of the Seleucids, or soon afterwards, the coinage bearing the heads of the Athenians to the godhead, and its land, with that of Simyra, was parcelled out among the Aradians (Strabo xvi. 2, 12). Akko issued coins of its own down to 267 B.C., if the reckoning was from the Seleucid era (312 B.C.); in 267 it was converted into a Greek city by Phoeni, and called Pholemais (Polyb. iv. 37; Strabo xvi. 2, 25; cf. Acts xxi. 7). Laodicea of Libanus was founded by Seleucus Nicator on the plain south-east of Hemesa (Hom) in the region of the upper Orontes, and became an important city: its coins of the 2nd century B.C. bear the interesting legend in Phoenician, "Of Laodicea which is in Canan (cf. CIS, i. 7–NSI, No. 9; Clermont-Ganneau, Rocce, t. v.)."

Another Laodica "by the sea" (ad mare), also of Seleucid foundation, is probably to be identified with the ruined site called Um-nu el-'Awhid, near the coast between Tyre and Akko; several Phoenician inscriptions have been found there (e.g. CIS, xvi. 3, 2), and Arab robbers plundered their territories from strongholds in the Lebanon. From 83–69 B.C. the entire kingdom was held by the Armenian Tigranes.

The death of Antiochus IV. Epiphanes in 164 B.C. revolts and adventurers made their appearance in many parts of Syria, heralding the collapse of the kingdom of the Seleucids. Berytus was destroyed by the usurper Tryphon in 140 B.C. Tyre in 120 and Sidon in 112 received complete independence, and inaugurated new eras from these dates. Byblus and Tripolis fell into the hands of "tyrants" (Strabo xvi. 2, 18; Jos. Ant. xiv. 3, 2), and Arab robbers plundered their territories from strongholds in the Lebanon. From 83–69 B.C. the entire kingdom was held by the Armenian Tigranes.

At last in 64 B.C. Pompey arrived upon the scene and established order out of chaos. Phoenicia was incorporated into the Roman province of Syria; Aradus, Sidon, Tyre and Tripolis were confirmed in their rights of self-government and in the possession of their territories. In 14 B.C. Augustus rebuilt Berytus as a Roman colony and stationed two legions there; later on Tolemais, Tyre and Sidon received colonial status. Under the beneficent government of Rome the chief towns prospered and extended their trade; but the whole character of the country underwent a change. During the Macedonian period Greek influence had been encouraged in the government of Phoenicia; relations with the Greek world grew closer; the native language fell into disuse, and from the beginning of the Roman occupation Greek appears regularly in inscriptions and on coins, though on the latter Phoenician legends do not entirely vanish till the 2nd century A.D.; while the extent to which Hellenic ideas penetrated the native traditions and mythologies is seen in the writings of Philo of Byblus. For the purposes of everyday life, however, the people spoke not Greek, but Aramaic. As elsewhere, the Roman rule tended to obliterate characteristic features of national life, and under it the native language and institutions of Phoenicia became extinct.

**Navigation, Trade, Colonies.**—The Phoenicians were essentially a seafaring nation. Fearless and patient navigators, they ventured into regions where no one else dared to go, and, always with an eye to their monopoly, they carefully guarded the secrets of their trade routes and discoveries, and their knowledge of winds and currents. At the beginning of the 7th century B.C. a Phoenician fleet is said to have circumnavigated Africa (Herod. iv. 42). To the great ports of Phoenician ships and sailors were independent; Saleph, Berytus, Tyre, Athens, and Alexandria, all in turn employed them for their transports and sea-fights. Even when Athens had developed a rival navy, Greek observers noted with admiration the discipline kept on board the Phoenician ships and the skill with which they were handled (Xen. Anc. viii.); all the Phoenician vessels from the round merchant-boat (yālūs) from which the island of Gaulus, now Gozo, near Malta, was called to the great Tarshish-ships, the “East-Indiamen” of the ancient world, excelled those of the Greeks in speed and equipment. As E. Meyer points out, the war between the Greeks and the Persians was mainly a contest between the sea-powers of Greece and Phoenicia. At what period did Phoenicia first rise to be a power in the Mediterranean? We are gradually approaching a solution of this obscure problem. Recent discoveries in Crete (xvi.) have brought to light the existence of a Cretan or “Minoan” sea-power of remote antiquity, and it is clear that a great deal of what used to be described as Phoenician must receive quite a different designation. The Minoan sea-power was at last broken up by invaders from the north, and a Carian rule became dominant in the Aegean (Herod. i. 171; Thucyd. i. 4, 8). It was a time of disordor and conflict due to the immigration of new races into the ancient seats of civilization, and it synchronized with the weakening of the power of Egypt in the countries which bordered on the eastern Mediterranean. This was in the 12th century B.C. The Tyrian trader saw that his opportunity was come, and the Aegean lay open to his merchant vessels. Where much is still obscure, all that seems certain is that the antiquity of Phoenicia as a sea and trading power has been greatly exaggerated both in ancient and in modern times; the Minoan power of Creuses preceded it by many centuries; the influence of Phoenicia in the Aegean cannot be carried back much earlier than the 12th century B.C., and, comparatively speaking, it was "foreign, late, and precarious."

A vivid description of the Phoenicians’ trade at the time of Tyre’s prosperity is given by Ezekiel (xxviii. 12–25), and it shows how extensive were their commercial relations not only by sea, but by land as well. It was they who distributed to the rest of the world the wares of Egypt and Babylonia (Herod. i. 1). From the lands of the Euphrates and Tigris regular trade-routes led to the Mediterranean with trading-stations on the way, several of which are mentioned by Ezekiel (xxviii. 23). In Egypt the Phoenician merchants soon gained a foothold; they alone were able to maintain a profitable trade in the anarchic times of the XXIInd and XXIIIrd Dynasties (825–500 B.C.), when all other foreign merchants were frightened away. Though there were never any regular colonies of Phoenicians in Egypt, the Tyrians had a quarter of their own in Memphis (Herod. ii. 112). The Arabian caravan-trade in perfume, spices and incense passed through Phoenician hands on its way to Greece and the West (Herod. iii. 107); these articles of commerce were mainly produced not in Arabia, but in East Africa and India, and the trade between the two had been known in the earlier period of the wealthy state of Sheba in Yemen. Between Israel and Phoenicia, relations naturally were close; the former provided certain necessaries of life, and received in exchange articles of luxury and splendour (Ezek. xxvii. 16–18). 8 Israeliite housewives sold their homespun to Phoenician peddlers (Prov. xxxi. 24 R.V.M.); in Jerusalem Phoenician merchants and money-lenders had their quarters (Zeph. i. 11), and after the Return we hear of Tyrians selling fish and all manner of wares in the city (Neh. xiii. 16), and introducing other less desirable imports, such as foreign cults (Isa. lxv. 11). The Phoenician words which made their way into Greek at an early period indicate the kind of goods in which the Phoenicians traded with the West, or made familiar through their commerce; the following are some of them—χρυσός, χιτών, βάλλος, θάνατος, μισθός, νάξος, κόμπος, φίλοι, μαύρα, παλαιάς, βασιλέας. Another valuable article of commerce which the Phoenicians brought into the market was amber. They could hardly have fetched it themselves from the Baltic or the North Sea; it came to them by two well-marked routes, one from the Baltic to the Adriatic, the other up the Rhine and down the Rhone. A deposit of amber has also been found in the Lebanon, and perhaps the Phoenicians worked this and concealed its origin.

1 Burrows, Discoveries in Crete (1907), 140 seq. It may be noted that the traditional or conjectural dates based upon the list of the Thalassocentric preserves by Eusebius carry us back to the 12th century B.C. See Professor John L. Myres’s essay referred to above, § iii. (4).

2 See Eupolemus (140–100 B.C.) quoted by Alexander Polyhistor, who, in a supposed letter from Solomon to the king of Tyre, mentions the food-supplies required by the Tyrians and promised from Palestine (Fr. Hist. Gr. iii. 220).
The Phoenician colonies were all supposed to have been founded from Tyre: with regard to the colonies in Cyprus and north Africa this was undoubtedly true. Cyprus possessed resources of timber and copper which could not fail to tempt the keen-eyed traders across the water, who made Citium (from Kittim, the name of the original non-Semitic inhabitants) their chief settlement, and thence established themselves in Idalium, Tamasus, Lapethus, Larnaka, Qarth-hadashad (Karti-hadasi) and other towns. In the inscriptions of the 4th to 3rd centuries, the Phoenician potencies in the island call themselves "kings of Kition and Idalion" (NSI. pp. 55-89). But the Phoenician rule was not so ancient as used to be supposed. At an early period Greeks from the south coast of Asia Minor had settled in Cyprus before the Phoenicians founded any colonies there; and it is noticeable that in the Assyrian tribute-lists of the latter half of the 7th century (KB. ii. pp. 149, 241) not one of the seven Cyprian kings mentioned appears to be Phoenician by name. Menander states (Jos. Ant. ix. 14, 2) that the kings of Tyre ruled over Cyprus at the close of the 6th century; but a clear proof that the Phoenician rule was neither ancient nor uninterrupted is given by the fact that the Cyprian Greeks took the trouble to invent a Greek cuneiform character (Cypriote) modelled on the Assyrian.

Homer represents the Phoenicians as present in Greek waters for purposes of traffic, but not as settlers (II. xxiii. 744). They occupied trading-stations on some of the Aegean islands and on the Isthmus of Corinth. One of their objects was the collection of murex, of which an enormous supply was needed for the dyeing industry; specially famous was the purple of the Laconian waters, the isles of Elishah of Ezek. xxvii. 7. But a great deal of what was formerly assigned to Phoenician influence in the Aegean at an early period—pottery, ornaments and local myths—must be accounted for by the vigorous civilization of ancient Crete. In the Greek world the Phoenicians made themselves heartily detested; their characteristic passion for gain (διά Ποινήματος, Plut. Rep. iv. 435 E.) was not likely to ingratiate them with those who were compelled to make use of their services while they suffered from their greed.

Farther west in the Mediterranean Phoenician settlements were first planted in Sicily, on the south coast, at Heracles or Ras Melqart; the islands between Sicily and Africa, Melita (Malta) on account of its valuable harbour, Gaulus and Cossura were also occupied (Diod. v. 12); and a beginning was made with the colonization of Sardinia and Corsica; but farther west still, on the Atlantic coasts to the right and left of the straits, more permanent colonies were established. It was the trade with Tarshish, i.e. the region of Tartessus in south-west Spain, which contributed most to the Phoenicians' wealth; for in this region they owned not only profitable fisheries, but rich mines of silver and other metals. The profits of the trade were enormous; it was said that even the anchors of ships returning from Spain were made of silver (Diod. v. 35). From Gadeira (Punic Tangier, n. Spain), which was built on an island near the mouth of the Guadaluver, the Sidonian ships ventured farther on the ocean and drew tin from the mines of north-west Spain or from the richer deposits in the Cassiterides, i.e. the Tin Islands. These were discovered to be, not a part of Britain as was imagined at first, but a separate group by themselves, now known as the Scillies; hence it is improbable that the Phoenicians ever worked the tin-mines in Cornwall.

The rich trade with Spain led to the colonization of the West. Strabo dates the settlements beyond the Pillars of Hercules soon after the Trojan War (l. 3, 2), in the period of Tyre's first expansion. Lixus in Mauretania, Gades and Utica, are said to have been founded, one after the other, as far back as the 12th century B.C. Most of the African colonies were no doubt younger; we have traditional dates for Azoa (887-855) and Carthage (873). A large part of North-west Africa was colonized from Phoenicia; owing to these first settlers, and after them to the Carthaginians, the Phoenician language became the prevailing one, just as Latin and Arabic did in later times, and the country assumed quite a Phoenician character.

In the days of Tyre's greatness her power rested directly on the colonies, which, unlike those of Greece, remained subject to the mother-city, and paid tithes of their revenues to its chief god, Melqart, and sent envoys annually to his feast. Then at the beginning of the 5th century B.C. the colonial power of Tyre began to decline; on the mainland and in Cyprus the Assyrians gained the upper hand; in the Greek islands the Phoenicians had already been displaced to a great extent by the advancing tide of Dorian colonization. But as Tyre decayed in power the colonies turned more and more to Carthage as their natural parent and protector. For effective control over a colonial empire Carthage had the advantage of situation over far-away Tyre; the traditional bonds grew lux and the ancient dues ceased to be paid, though as late as the middle of the 6th century Carthaginian rendered tithes to the Tyrian Melqart. And the mother-country cherished its claims long after they had lost reality; in the 2nd century B.C., for example, Sidon stamped her coins with the legend, "Mother of Kambé (i.e. Carthage), Hippo, Kition, Tyre" (VII. 1. 3, 193).

Manufactures, Inventions, Art.—From an early date the towns of the Phoenician coast were occupied, not only with distributing the merchandise of other countries but with working at industries of their own; especially purple-dyeing and to a lesser extent (II. vi. 289 sqq.), metal work in silver, gold and electrum (II. xxi. 741 sqq.; Od. iv. 615 sqq., xv. 458 sqq.), and glass-work, which had its seat at Sidon. The iron and copper mines of Cyprus (not Sidon, as Homer says, II. xi. 436), were worked, and copper and iron were fashioned into articles of commerce. Egyptian monuments frequently mention the vessels of gold and silver, iron and copper, made by the Dahi, i.e. the Phoenicians (W. M. Müller, As. u. orient. 306); and in Cyprus and at Nimrud bronze and silver paterae have been found, engraved with Egyptian designs, the work of Phoenician artists (see table-cases C and D in the Nimrud gallery of the Brit. Mus.). The invention of these various arts and industries was popularly ascribed to the Phoenicians, no doubt merely because Phoenician traders brought their products into the markets. But of glass and embroidery it probably came from Babylon in the first instance; glass-making seems to have been borrowed from Egypt; the invention of arithmetic and of weights and measures must be laid to the credit of the Baby
doans; and the Egyptians, as we have seen, seem to have built the alphabet (e.g. Pline, N.H. v. 13, cf. v. 57; Lucan, Bell. civ. iii. 220 sqq.). It is, however, unlikely that any genuine tradition on the subject existed, and the Phoenician theory has found favour with modern times only to much question. The Phoeni
cians cannot be said to have invented any of the arts or industries,
which, as the ancient world imagined; but what they did was something hardly less meritorious: they developed them with singular skill, and in consequence they made them practical.

The art of Phoenicia is characterized generally by its dependence upon the art of the neighbouring races. It struck no original line of its own, and borrowed freely from foreign, especially Egyptian, sources. In this respect the remains of Phoenician art do not show clearly the source to which the Phoenician artists went for inspiration; for example, the uraeus-frieze and the winged disk, the ankh or symbol of life, are Egyptian designs frequently imitated. It was in the times of the Persian monarchy that Phoenician art reached its highest development, and to this period belong the oldest sculptures and coins that have come down to us. A characteristic specimen of the former is the stele of Yehaw milk, king of Gebal (Gades) (741), in which the king is represented in Persian dress, and the goddess to whom he is offering a bowl looks exactly like an Egyptian Isis-Hathor; the inscription mentions the various objects of bronze and gold, engraved work and temple furniture, which the king has set up. The Phoenicians may be divided into two great periods: in the first, from the earliest times to the 4th century B.C., Egyptian influence and then Babylonian or Syrian influence is predominant, but the national element is frequently in evidence, which, if it has not preserved, at least sustained, the mystery, and the native element, though making itself felt, is much less obtrusive. Throughout these periods works of art, such as statues of the gods and sarcofagi, were imported directly at first from Egypt, and then the countries of Canaan and Egypt used to be worked. The finest sarcofagi that have been found in the necropolis of Sidon (now in the Imperial Museum, Constantinople) are not Phoenician at all, but exquisite specimens of Greek art. The Phoenicians spent much care on their burial-places, which have furnished the most important

1. Traces of ancient mining for iron have been found in the Lebanon; cf. LXX. 1 Kings ii. 46c (ed. Swete), which has been taken to refer to this quarrying in search of iron. Jer. xv. 12. See Benzingia on 1 Kings ix. 19.
monuments left to us. The tombs are subterranean chambers of varied and often irregular form, sometimes arranged in two stores, sometimes in several rows one behind the other. While in early times a mere perpendicular shaft led to these excavations, at a later period the shafts were cut obliquely, and the tombs were buried either in the floor (often in a sarcophagus), or, according to later custom, in niches. The mouths of the tombs were walled up and covered with slabs, and occasionally cippi (Phoen. maq̱̱bāḥā) were set up before them. The word cippus, popularly called maq̱̱bāḥā, i.e. "spindles," above the tombs near Amrit, have peculiarities of their own; some of them are adorned with lions at the base and with roofs of pyramidal shape. Besides busts, statues and other sculptures of the second Egyptian period, the smaller objects usually found are earthen pitchers and lamps, glass-ware, tesserae and gems. Of buildings which can be called architectural few specimens now exist on Phoenician soil, for the city did not possess the resources or the desire to construct public monuments. The temple of the goddess of Song, however, was a magnificent building. Of its remains, the most interesting are the necropoleis at near Amrit, recencavations at Bostan-esh-Shék, near Sidon where uneartked parts of the enclosure or foundations of the temple of Eshmun (NSI, p. 401); the conduits of Ras el-Ain, south of Tyre, are considered to be of ancient date. With regard to the plan and design of a Phoenician temple, it is probable that they were in many respects similar to those of the temple at Jerusalem, and the probability is confirmed by the remains of a sanctuary near Amrit, in which there is a cela standing in the form of the temple of Solomon in Jerusalem. But no architectural remains of other buildings in an Egyptian style. The two pillars before the porch of Solomon's temple (1 Kings vii. 21) remind us of the two pillars which Herodotus saw in the temple of Melqart at Tyre (Herod. ii. 64). Among the other buildings is the temple of Paphos and Hierapolis (see W. R. Smith, Rel. of Sem. p. 468 seq.).

Religion. -Like the Canaanites of whom they formed a branch, the Phoenicians connected their religion with their great powers and personifications of nature. The gods who presided over each of them belonged essentially to the earth; the fertile field, trees and mountains, headlands and rivers and springs, were believed to be inhabited by different divinities, who were therefore worshipped, and the people, under the guidance of the priests, were in a state of semi-feudalism. The Phoenicians were divided into guilds, and each guild had its own god or goddess. The gods of the Phoenicians were of the same order as the Egyptian gods, the Phoenicians called "Elonim, Elohim," Plautus uses alonium solvum for "gods and goddesses" (Poes. v. 1, i). These plural forms go back to the singular forms of the Phoenician God, and the number of the plural is at all common in the inscriptions (NSI, p. 28, 31, 51). El is by itself has been found only once; the stem 'Elah is also rare (ibid., pp. 135, 155). The god or goddess was generally called the "el," or god, to whom they worshipped. The "el," or god, was the only Canaanites, but by the Aramaeans (Beel) and Babyloni ans (Bel) as well. There was no one particular god called "Baal." The name was not a proper name but an appellative, a description of the god. The word Baal comes from the Hebrew word Beel, meaning "god," or the name of Melqart, or Melqarth, or Melek, "Amma, which means king, lord, mother," the god himself was named or had no name. Occasionally we know what the name was; the Baal of Tyre was Melqart (Melkart), another of this people merely "Tyrian Melqart," while a Phoenician the Baal of Hara, the moon, with the Sem. tv, city or district had its own Baal, the author of its fertility, the "husband" (a common meaning of Baal) of the land which he fertilized. There were many gods, and the Old Testament writers could allude to the Baalim of the neighboring Canaanites. Sometimes the word god received a distinguishing attribute which indicates an association not with any particular place, but with a special characteristic; the most common forms are Baal-bammân, the chief deity of the Phoenicians, and Baal, or Baal-bemmân, a god of fertility, and Baal-shamem, "Baal of the heavens." The latter deity was widely venerated throughout the North-Semitic world; his name, which does not appear in the Phoenician inscriptions, is considered by some to be derived from the Hebrew "Baal" and the Semitic "Baal." The Baal of the heavens was the universal conception of deity than existed in the earlier days. 6

1. Cf. Hannibal's oath to Philip of Macedon; beside the named deities he invokes the gods of "sun and moon and earth, and rivers
and meadows and waters." (Polyb. vii. 9.)
2. This is well brought out by G. F. Hill, Church Quarterly Rev. (April, 1841), who specially emphasizes the evidence of the Phoenician coins.
3. "To the lord 'El, which Ba'al-shilem . . . vowed," &c.;
5. "He avenged the murder that causes sorrow." (see p. 375.) of Dan. xii. 11, xi. 31, &c., is an intentional disfigurement of the verb. 6
6. The name has been found on an important Aramaic inscription from North Syria, dating c. 800 B.C., in which Zikar, king of Hamath and Laaish frequently speaks of his god 'Beel-shamim' (Pogon, Inscri. de la Syrie, 1908).

The worship of the female of the male principle was a strongly marked feature of Phoenician religion. To judge from the earliest evidence on the subject, the Ba'allath of Gebal or Byblus, referred to again and again in the Amarna letters (Bull. de la., 69, 70), was the same goddess as Ba'al, or Baal, the chief god of Tyre, and was considered as his mother. "She was the oldest and most renowned. The mistress of Gebal was no doubt 'Ashart (Astarat in Greek, 'Astarte in the Old Testament, pronounced with the vowels of behath, or behath, behath, behath, behath), or 'Astar, or Astarte, or Astart, or Ashtart, and, as used in Phoenician, is practically the equivalent of "goddess." She represented the principle of fertility and generation, references to her cult at Gebal, Sidon, Ashkelon, in Cyprus, page 105, at Paphos, in Sicily at Eryx, in Gaul, in Carthage, are frequent in the inscriptions and elsewhere. The common epithets Khârûm and Khârûm (of Kuthera in Cyprus), Cyriaphaia, show that she was identified with Aphrodite and Venus. Though few of her temples were found, the remarkable name "Melqarth," a war god, was frequently rendered Melfarthe, or Melfarthe, and is still common in modern times. Though this rendering is incorrect, and some scholars prefer "'Ashart of the heaven of Ba'al" (NSI, p. 37). Another goddess, specially honoured at Carthage, is Tanith (pronunciation uncertain); nothing is known of her characteristics; she is regularly connected with Ba'al on the Carthaginian votive tablets, and called "the face of Ba'al," i.e. his representative or revelation, though again some question this rendering as too metaphorical, and take "face of Ba'al" to be the name of a place, as if by the god's name. The site of Tanith seems to have been here: Eshmun, the god of vital force and healing, worshiped at Sidon especially, but also at Carthage and in the colonies, identified by the Greeks with Asclepius; Melqarth, the patron deity of Tyre, was worshipped in a temple of this name, and is called "lightning" god, especially popular in Cyprus and derived originally from Syria, whose name was called Apollo. A tendency to form a distinct deity by combining the attributes of two produced such forms as Melqart, Melqarthe, or Melfarthe; and by combining Eshmun, Melqarthe-res, &c. As in the case of art and industries, so in religion the Phoenicians readily assimilated foreign ideas. The influence of Egypt was especially strong (NSI, pp. 62, 69, 148, 154); but the results of this contact are not so clearly marked as above, all has the appearance of Isis, who, according to the legend preserved by Plutarch (de Is. et Os. 15), journeys to Byblus, where she was called Astarte. The Phoenicians settlers at the Peiraeus worshipped this goddess, and the temple built there was surrounded with the names of Babylonian and Arabian deities (NSI, p. 101). Closer intimacy with the Greek world naturally brought about modifications in the character of the native gods, which became apparent when Ba'al of Sidon or Ba'al-shamim was identified with Zeus, Tanith with Demeter or Artemis, 'Anath with Athena, &c.; the notion of a supreme Ba'al, which finds expression in the Greek Belos and Baalos or Belmons (the goddess of Byblus), was no doubt introduced by the Phoenicians in the course of their contact with the Greeks. The Phoenicians produced a considerable effect upon Greek and Roman religion, especially from the religious centres in Cyprus and Sicily. A great number of divinities are known only as elements in proper names of the Greek and Latin names, the "Baal" and "Melqart" fresh ones are continually being discovered. It was the custom among the Phoenicians, as among other Semitic nations, to use the names of the gods in forming proper names and thus express devotion to Ba'al or the Ba'al. But the name Ba'al as a part or whole of the name Ba'alshamim, I, 'Ashart, Eshmun-azar. The proper names further illustrate the way in which the fission of man to God was regarded; the commonest forms are servant (ibid., e.g. 'Abd-ashart, "member of food," or "Abd-melqart), client or guest (ibid., e.g. "God-eshmun"); the religious idea of the guest of a deity had its origin in the social custom of extending hospitality to a stranger and in the old Semitic right of sanctuary. The interpretation of such names as Abi-the Ba'al (father of the Ba'al), or Kulluh (brother of Kilk, Kulluh (brother of the exalted one) is not altogether certain, and can hardly be discussed here. 7

8. Probably like other Canaanites the Phoenicians offered worship "on every high hill and under every green tree"; but to judge from inscriptions (ibid., pp. 105, 106), and from a passage in the Temple of Eshmun, the Ba'al or 'Ashart of a place was usually worshipped at a temple, which consisted of a court or enclosure and a roofed cell with a portion of wall having a hole at the entrance. In the court stood a conical stone, probably the symbol of Astarte, as on the Roman coins of Byblus (illustrated in Rawlinson, Phoenicia, 146, Perrot et Chipiez, Hist. de l'Anc. Etr., iii. 60, see also Ohnefalsch-Richter, Cyprus, pl. I, the temple of Eshmun at Sidon, fig. 3) where sacred stones were set up in the sanctuaries (NSI, Nos. 13 seq., 23-27, 30, &c.); and besides these the baetyl (meteoretic stones) which were regarded as symbols of the gods. Pillars, again, had a prominent place in the court or before the shrine (ibid., ibid., pp. 102 seq.), but it is not known whether the sacred pole (ashkera), an invariable feature of a Canaanite sanctuary, was usual in a Phoenician temple (ibid., pp. 50 seq.).

PHOENIX (Gr. φοινίξ), a fabulous sacred bird of the Egyptians.

The Greek word is also used for a date-palm, a musical instrument like a guitar, and the colour purple-red or crimson. According to the story told to Herodotus (ii. 73), the bird came from Arabia every 500 years, bearing its father embalmed in a ball of myrrh, and buried him in the temple of the sun. Herodotus, who had never seen the phoenix himself, did not believe this story, but he tells us that the picture of it represented a bird of golden colour, which was equal in size and shape. According to Pliny (Nat. hist. x. 2), there is only one phoenix at a time, and he, at the close of his long life, builds himself a nest with twigs of cassia and frankincense, on which he dies; from his corpse is generated a worm which grows into the young phoenix. Tacitus (Ann. vi. 28) says that the young bird lays his father on the altar in the city of the sun, or burns him there; but the most familiar form of the legend is that in the Physiologus (q.v.), where the phoenix is described as an Indian bird which subsists on air for 500 years, after which, having wings with spicis, he flies to Helipolis, enters the temple there, and is burned to ashes on the altar. The bird is thus a phoenix and is already feathered; on the third day his pinions are full grown, he salutes the priest and flies away. The period at which the phoenix reappears is very variously stated, some authors giving as much as 1461 or even 7006 years, 500 years being the period usually named; and Tacitus tells us that the bird was said to have appeared first under Senecio (Seswost), then under Amasis (AhmoI), under Ptolemy III., and once again in A.D. 43, after an interval so short that the genuineness of the last phoenix was suspected. The phoenix that was shown at Rome in the year of the secular games (A.D. 47) was universally admitted to be an imposture.

The form and variations of these stories characterize them as popular tales rather than official theology; but they evidently must have had points of attachment in the mystic religion of Egypt, and both Horapollo and Tacitus speak of the phoenix as a symbol of the sun. Now we know from the Book of the Dead, and other Egyptian texts, that a stork, heron or egret called the benu (the name means "dawn") was one of the sacred symbols of the worship of Helipolis, and A. Wiedemann ("Die Phönix-Sage im alten Ägypten" in Zeitschrift für ägyptische Sprache, xvi. 89) has made tolerably clear that the benu was a symbol of the rising sun, whence it is represented as "self-generating" and called "the soul of Ra (the sun)", "the heart of the renewed Sun." The earliest symbol of the morning sun, especially in connexion with the doctrine of the future life, could thus be transferred to the benu, and the language of the hymns in which the Egyptians praised the luminary of dawn as he drew near...
PHOENIX—PHONETICS

from Arabia, delighting the gods with his fragrance and rising from the singing flames of the morning glow, was enough to suggest the attributes of the traits materialized in the classical pictures of the phoenix. That the *benn* is the prototype of the phoenix is further confirmed by the fact that the former word in Egyptian means also "palm-tree," just as the latter does in Greek. The very various periods named make it probable that the periodical return of the phoenix belongs only to vulgar legend, materializing what the priests knew to be symbolic. Of the birds of the heron family the gorgeous colours and plummed head spoken of by Pliny and others would be least inappropriate to the purple heron (*Ardea purpurea*), with which, or with the allied *Ardea cinerea*, it has been identified by Lepsius and Peters (*Alteste Texte des Todtenbuchs*, 1867, p. 51). But the golden and purple hues described by Herodotus may be the colours of sunrise rather than the actual hues of the purple heron. How Herodotus came to think that the bird was like an eagle is quite unexplained; perhaps this is merely a slip of memory.

Many commentators still understand the word *ḥab, ḫōh, ḫōb*, in Job xxix. 18 (A.V. "sand" of the phoenix). This interpretation is perhaps as old as the (original) Septuagint, and is current with the later Jews. Among the Arabs the story of the phoenix was confused with that of the Indian phoenix or sândak (Damir, ii. 36 seq.) is represented sometimes as a quadruped, sometimes as a bird. It was firmly believed in, for the incombustible cloths woven of flexible asbestos were popularly thought to be made of its hair. Phoenix, as a character in the works of Herodotus, is already mentioned by the Egyptians (cf. Yaacov, *Mitt. Ostasiat.*, 520, and Dozy, e. v.). The *ţanak* (Pers. *simurgh*), a stupendous bird like the rook (rūkh) of Marco Polo and the *Arabian Nights*, also borrows some features of the phoenix.

According to Kazwini (1420) it lives 1700 years, and when a young bird is hatched the parent of opposite sex burns itself alive. In the book of *Kalīla and Dimna* the *simūr* or *ţanak* is the king of birds, the Indian *garuda*, on whom Vishnu rides.

PHOENIX, the capital of Arizona, U.S.A., and the county-seat of Maricopa county, situated on the Salt River, in the south central part of the state. Pop. (1890), 3152; (1900), 5544 (1935 being foreign-born and 148 negroes); (1910) 11,134. It is served by the Arizona Eastern and the Santa Fé, Prescott & Phoenix railways, the former connecting at Maricopa (35 m. distant) with the Southern Pacific and the latter connecting at Ash Fork, near Prescott (104 m. distant), with the Atchison, Topeka & Santa Fé. The city is a popular winter and health resort, with a fine dry climate. The city is the see of a Protestant Episcopal bishopric. About 3 m. north of the city is the Phoenix (non-reservation) boarding-school for Indians, supported by the United States government, with an average attendance of about 700 pupils. The city lies in a great plain, in the centre of a region of pastures, gardens and orchards, the largest and most beautiful farming district of Arizona, irrigated with water stored by the great Roosevelt dam (about 70 m. north-east of Phoenix). Local interests are almost entirely in agriculture, stock-raising and fruit-growing. In the surrounding region are several large ostrich farms and a small exhibition ranch. Phoenix was settled in 1870, became the county-seat on the organization of Maricopa county in 1871, was incorporated in 1881, and became the capital of Arizona in 1889.

PHOENIX ISLANDS, a group of eight small islands in the Pacific Ocean, about 3° S., and 172° W., belonging to Great Britain. They have a land area about 16 sq. m. and a population of 50. Their names are Phoenix, Galapagos, Galapagos, Sara Hall, Sydney, Birnie, Enderbury, Canton (Mary) and McKean. To the north-west of the group (between the equator and 1° N.) lie two more islets—Baker and Howland. The islands were annexed by Great Britain in 1890–1892.

PHOENIXVILLE, a borough of Chester county, Pennsylvania, U.S.A., on the Schuylkill river at the mouth of French Creek, about 28 m. north-west of Philadelphia. Pop. (1890), 8354; (1900), 10196, of whom 2221 were foreign-born and 278 were negroes; (1910 census), 10,743. It is served by the Pennsylvania (Schuylkill division) and the Philadelphia & Reading railways, and by electric railway to Spring City (pop. in 1901, 2880), 5 m. north-west of Phoenixville on the Schuylkill. Phoenixville is chiefly a manufacturing borough. Its blast-furnaces and iron mills were long among the largest in the country, and the manufactory of steel is still the borough's predominant industry. Phoenixville was settled in 1732, and was incorporated in 1840.

PHONETICS (Gr. *φωνή, voice*), the science of speech-sounds and the art of pronunciation. In its widest sense it is the "science of voice," dealing not only with articulate, but also with the inarticulate sounds of animals as well as men. The originally synonymous term, "phonology," is now restricted to the history and theory of sound-changes. The most obvious of the practical applications of phonetics is to the acquisition of a correct pronunciation of foreign languages. But its applications to the study of the native language are not less important: it is only by the help of phonetics that it is possible to deal effectively with vulgarisms and provincialisms of pronunciation and secure uniformity of speech; and it is only on a phonetic basis that the deaf and dumb can be taught articulate speech. From a more theoretical point of view phonetics is, in the first place, the science of linguistic observation. Without phonetic training the dialectologist, and the missionary who is confronted with a hitherto unwritten language, can neither observe fully nor record accurately the phenomena with which they have to deal. These investigations were a great step in the development of the science of language. The modern philologists no longer despises colloquial and illiterate forms of speech. On the contrary, he considers that in them the life and growth of language is seen more clearly than in dead literary languages, on whose study the science of comparative philology was at first exclusively built up. It was not till philologists began to ask what were the real facts underlying the comparisons of the written words in Sanskrit, Greek, Latin, and the other Indo-European languages, embodied in such generalizations as Grimm's Law, that "letter-science" developed into "sound-science" (phonology). The rise and decay of inflexions, and the development of grammatical forms generally, are, from the formal point of view, mainly phonetic problems; and phonetics enters more or less into every department of historical and comparative grammar.

Methods of Study and Investigation.—Phonetics is the science of speech-sounds. But sounds may be considered from two opposite points of view—the organic and the acoustic. From the organic point of view a sound is the result of certain actions and positions of the organs of speech, as when we define *f* as a lip-teeth (dento-labial) consonant. This is the point of view of the speaker of a language. To the hearing, on the other hand, *f* is not a lip-teeth, but a huss consonant similar to that denoted by *th*. This is the acoustic point of view. Theoretically, the organic study of phonetics is a branch of anatomy and physiology: that part of these sciences which deals with the organs of speech (see MOUTH) and their functions (see VOICE); while, from the opposite point of view, the study of phonetics is based on that branch of physical science known as acoustics (see SOUND), together with the anatomy and physiology of the organs of Hearing (q.v.).

Unfortunately, this basis is still imperfect. The principles of acoustics are well established, and we know much about the anatomy of the ear. But how the ear transmits to the brain the impression of sound is still a mystery. Again, although the mechanism of the vowel is clear enough, there is still no generally received and acoustic theory of its formation. In fact, from the physical science point of view there is as yet no science of phonetics.

The real function of phonetics is philological and literary. The only sound basis of a theoretical knowledge of phonetics is the practical mastery of a limited number of sounds—that is to say, of the sounds which are already familiar to the learner in his own language. It is evident that the more familiar a sound is, the easier it is to gain insight into its mechanism and to recognize it when heard. It is indispensable to cultivate both the organic and the acoustic sense. These processes we are continually carrying out in ordinary conversation. All, therefore, that we have to do in dealing with native sounds is to develop this unconscious organic and acoustic sense into a conscious and analytic one. The first step is to learn to isolate each sound: to
pronounce it, as far as possible, apart from its context; and to preserve it unchanged through every variation of length and force, and in every combination of sounds. The next step is to analyze the sounds, and let the person pronounce the two consonants in such a word as fine by isolating and lengthening them till he can both hear and feel the voice-vibration in the second one. In the same way let him learn to feel the changes in the position of the tongue and lips in passing from one vowel to another. When the native sounds have been thoroughly studied in this way, the learner will proceed to foreign sounds, deducing each new sound from those which are already familiar to him.

The natural method of learning sounds is mainly a subjective one. We listen patiently till our ears are steeped, as it were, in the sound; and then, after repeated trials, we hit on the exact position of the organs of speech by which we can reproduce the sound to the speaker's satisfaction. But the natural method admits also of objective control and criticism of the movements of the lips and jaws by direct observation. The movements and positions of the tongue and soft palate, and other modifications of the mouth and throat passages are also more or less accessible to observation in the case of self-observation with the help of a small mirror held in the hand. If the mirror is small enough to go into the mouth, and is fixed obliquely to a handle, so that it can be held against the light. The use of such an apparatus as to reflect the light down the throat, we have the laryngoscope. Laryngoscopy has confirmed earlier results, and has also added to our knowledge of the throat sounds. But, on the other hand, it has been a fruitful source of error. There has been great discrepancy between the results obtained by different observers, and frequently results which were at first received with implicit confidence for their supposed rigorously scientific and objective character have been found to be worthless. It seemed at first as if Köhntgen's discovery of the so-called ‘primary shadow’ was the most fruitful observation of the positions of the tongue, not lengthways, but from the side, as also of the interior of the throat. But although the cheeks are to a certain extent transparent to these rays, the shadow of the tongue is obliterated by the saliva. It is more to be hoped that the shadow of the palate is more distinct when the tongue is under the palate.

But there are other methods besides those of direct observation by which the positions of the tongue may be objectively determined and measured with more or less accuracy. The interior of the mouth, and the position of the tongue, are the most obvious organs of pronunciation. If the little finger is held against the gums during the articulation of the vowels in it, at, et, the difference in the height of the tongue will at once become apparent; in the formation of the first vowel the tongue is pressed strongly against the artificial palate, while in that of the second it only just touches it, and in that of the third it does not touch at all.

Several forms of apparatus have been devised for a more accurate determination of the positions of the tongue and the other movable organs of the mouth. The earliest one is made of wire ‘palatograms’ which are obtained by Grandet, who uses disks of cardboard of various sizes fixed to silver wires. A full description of this and other methods will be found in Scripture's Elements of Experimental Phonetics, 2nd ed., 1892.

There are other methods whose results are obtained indirectly. The simplest of these are the palatographic, by which are obtained "palatograms" recording the contact of the tongue with the palate. The apparatus most generally used consists of a thin, shell-like artificial palate, which is covered with chalk and placed in the mouth; when the sound is made, the articulation of the tongue is inferred from the contact-marks on the plate. These devices have been used to a limited extent in its application. It, too, has the drawback of being far from a very clear indication of the sounds in the back of the mouth. The outlines of palatograms are much vaguer than they appear in the published drawings of them; and it is a question whether the thickness even of the thinnest plate does not make them useless.

The methods hitherto considered are all comparatively simple. They require no special knowledge or training, and are accessible to all. But there are more elaborate methods—with which the name "phonetic" has been wrongly associated—employing special training in practical and theoretical physics and mathematics, and requiring the help of often complicated and costly, and not easily accessible, apparatus. The investigation of the subject requires the phonograph and gramophone records is a technical example. Good examples of these methods are afforded by E. Meyer's investigations of vowel-quantity in English (Englische Lautdauer, Uppsala, 1903). Their characteristic feature is the delicacy, and the minuteness of their distinctions, which often go beyond the range of the human ear. Although their results are often of value, they must always be received with caution; the sources of error are so numerous.

The claims of instrumental phonetics have been so promiently brought forward of late years that they cannot be too often repeated that instrumental phonetics, is, strictly speaking, not phonetics at all. It is only a help: it only supplies materials which are useless till they have been tested and accepted from the linguistic phonetician's point of view. The final arbiter in all phonetic questions is the trained ear of a practical phonetician; differences which cannot be perceived must—or at least may be—ignored: what contradicts the trained ear cannot be accepted.

Sound-Notation; Spelling Reform.—Next to the analysis of the sounds themselves, the most important problem of phonetics is their representation by means of written and printed symbols. The traditional or "nomic" orthographies of most languages are only imperfectly phonetic. And, unfortunately, of the languages in most general use, two are exceptionally unphonetic in their orthographies, French showing the greatest divergence between sound and symbol, while English shows the maximum of irregularity and arbitrariness. The German orthography is comparatively phonetic: it has hardly any silent letters, and generally has one symbol for each sound, each symbol having only one value, the exceptions falling under a few simple rules, which are easily remembered. There are other languages which have still more phonetic orthographies, such as Spanish, Welsh or Dutch. But, in these, as in all languages, even when they are not actually misleading, they are always inadequate. On the other hand, no system of writing is wholly unphonetic. Even in French and English there are many words whose spelling not even the most radical reformer would think of altering. In fact, all writing which has once emerged from the hieroglyphic stage is at first purely phonetic, as far as its defective means will allow. The divergence between sound and symbol which makes spelling unphonetic is the result of the retention of phonetic spellings after they have become unphonetic through changes in the pronunciation of the words themselves. Thus, such English spellings as knight and tonight were still phonetic in the time of Chaucer; for at that time the initial consonants of these words were still pronounced, and the gh still had the sound of ch in German ich. So also see and sea are written differently, not by way of arbitrary distinction, but because they were pronounced differently till within the last few centuries—as they still are in Irish-English.

Where there is no traditional orthography, as when Old English (Anglo-Saxon) was first written down in Latin letters, spelling was necessarily phonetic; but as the language became larger and more detailed the handwriting of the scribes, the influence of the traditional orthography becomes stronger, till at last the invention of printing and the diffusion of one standard dialect over a large area occupied originally by a variety of other dialects makes changes of spelling as inconvenient as they were once easy and natural. The ideal orthography for printers is one which is absolutely uniform over the whole territory of the language, and absolutely unchangeable. In such orthographies as those of the present English and French there is no longer any living correspondence between sound and symbol: they are, in intention at least, wholly unphonetic; they are preserved by graphic, not by oral, tradition.

But unphoneticness has its practical limits. A purely unphonetic degradation of an originally phonetic system of writing—one in which there is absolutely no correspondence between sounds and letters—could not be mastered even by the most retentive memory: it would be even more difficult than the Chinese writing. Hence a phonetic reaction is inevitable. In the middle ages the spelling was periodically readjusted in accordance with the changes of pronunciation—as far, of course, as the imperfections of the existing orthography would allow. The philosophical writer, on the other hand, considered the importance of printing. In fact, it is only within the last hundred years or so that the orthographies of English and French have become fixed.

One result of this fixity is that any attempt to continue the process of adjustment assumes a revolutionary character. When, in 1846, the pioneers of the modern spelling-reform
PHONETICS

movement—A. J. Ellis and I. Pitman—brought out the Phonetic
Nuz, few of those who joined in the chorus of ridicule excited by
the new alphabet stopped to consider that this uncouthness was
purely the result of habit, and that the Authorized Version of
the Bible in the spelling of its first edition would seem to us not
less strange and uncouth than in the new-fangled typoty of
Messrs Ellis and Pitman. Nor did they stop to consider that
phonetics and phonetic spelling, so far from being innovations,
are as old as civilization itself. The Alexandrian grammarians
were not only phoneticians—they were spelling-reformers; they
invented the Greek accents for the purpose of making the pro-
nunciation of Greek easier to foreigners. The Romans, too, were
phoneticians: they learnt Greek by phonetic methods, and paid
great attention to niceties of pronunciation. The Sanskrit
grammarians were still better phoneticians.

As a matter of fact, English spelling was still phonetic as late
as the time of Shakespeare—in intention, at least. But although
people still tried to write as they spoke, the inherited imperfections
of their orthography made it more and more difficult for
them to do so. Hence already in the 16th century a number of
spelling-reformers made their appearance, including classical
scholars such as Sir John Cheke, and A. Gill, who was head-master
of St Paul’s School in London. Gill has left us extracts from
Spenser’s Faerie Queene in phonetic spelling; but, strange to
say, nothing of Shakespeare’s, although he and Shakespeare
were exact contemporaries. But Gill’s and the other alphabets
proposed were too intricate and cumbrous for popular use.

Nevertheless, some important phonetic reforms were success-
fully carried through, such as getting rid of most of the super-
fluous final e’s, utilizing the originally superfluous distinctions
in form between i and j, u and v, by using i, u only as vowels,
j, v only as consonants, instead of at random—a reform which
seems to have begun in Italy. Another important reform was the
introduction of oe and ou, as in see and boat, which had hitherto
been written with ee and oo, being thus confused with see and boot.

All these were as much phonetic reforms as it would be to
utilize long s and tailed z (\(z\)) to denote the final consonants in
fish and rouge respectively; a reform first suggested by A. J.
Ellis, who was himself the first to call attention to the works of
these early phoneticians and to utilize them in the investiga-
tions enshrined in his great work on Early English Pronunciation.

With all its defects, the present English spelling is still mainly
phonetic; we can still approximately guess the pronunciation of
the vast majority of words from their spelling. So when we
say that English spelling is unphonetic we merely mean that
it is a bad phonetic spelling; and all that spelling-reformers aim
at is to make this bad into a good phonetic spelling, that is, an
efficient and easy one. But the difficulties are great; and the
more we know of phonetics, and the more we experiment with
different systems of spelling, the more formidable do they appear.
One of the difficulties, however, that is commonly supposed to
stand in the way of spelling-reform is quite imaginary: namely,
that it would destroy the historical and etymological value of
the English language. Thus E. W. Freeman used to protest
against this as "a reckless wiping out of the whole history of
the language." Such critics fail to see that historical spelling, if
carried out consistently, would destroy the materials on which
alone history can be based; that these materials are nothing else
but a series of phonetic spellings of different periods of the
language, and that if a consistent historical and etymological
spelling could have been kept up from the beginning, there would
have been no Grimm’s Law, no etymology; in short, no com-
parative or historical philology possible.

The advantages of beginning a foreign language in a phonetic
notation are many and obvious. In the first place, the learner
who has once mastered the notation and learnt to pronounce the
sounds the letters stand for, is able to read off at once any text
that is presented to him without doubt or hesitation, and without
having to burden his memory with rules of pronunciation and
spelling. Another advantage of phonetic spelling is that when the
learner sees the words written in a representation of their
actual spoken form he is able to recognize them at once when
he hears them. And if the learner begins with the phonetic
notation, and uses it exclusively till he has thoroughly mastered
the spoken language, he will then be able to learn the ordinary
spelling without fear of confusion, and quicker than he would
otherwise have done.

Spelling-reform may be carried out with various degrees of
thoroughness. After the failure of many schemes of radical
reform, an attempt was made to begin with those numerous
spellings which are both unphonetic and unhistorical, or are
against the analogy of other traditional spellings. Accordingly,
in 1881 the Philological Society of London "aprov’d (sic) of
certain partial corrections (sic) of English spellings," which were
also approved of by the American Spelling-reform Association;
and a list of them was issued jointly by the two bodies, and
recommended for general adoption. A similar movement
has been started in France. But the general feeling appears to
be that it is better to keep the ordinary spelling unchanged, and
wait till it is possible to supersede it by one on a more or less
independent basis.

If the existing Roman alphabet is made the basis of the new
phonetic notation of any one language, the most obvious course
is to select one of the various traditional representations of each
sound, and use that one symbol exclusively, omitting, of course,
at the same time all silent letters. A. J. Ellis’s English Glosic
is an example of such a phonetic spelling on a national basis. The
following is a specimen—

Inghlish Glosik iz veri eez reed. Wit proper training a child foil yeerz oldd kan bee redli tru too reed Glosik buoks.

But a system which, like this, writes short and long vowels
with totally different symbols (i, ee) is only half phonetic: it is
phonetic on an unphonetic basis.

A fully phonetic system, in which, for instance, long vowels
and diphthongs are expressed by consistent modifications or
combinations of the symbols of the short vowels, and in which
simple sounds are, as far as is reasonable and convenient,
expressed by single letters instead of digraphs such as sh, must
necessarily discard any national basis. The best basis on the
whole is obtained by giving the letters their original common
European sounds, i.e. by returning to the Late Latin pronunciation,
with such modifications and additions as may be advisable.
As regards the vowels at least, this Latin basis is very well
preserved in German and Italian. In French, on the other hand,
the Latin tradition was greatly corrupted already in the earliest
period through the rapid changes which the language underwent.
Thus when the Latin u in luna assumed the sound it now has
in French lune, the symbol u was still kept; and when the sound
u afterwards developed again out of the diphthong ou, this digraph
was used to denote the sound. So when the French system of
spelling came into use in England after the Norman Conquest
these phonetic symbols were introduced into English spelling,
and that such a word as Old English and Early Middle English
hus, “house,” was written hous in the Late Middle English
of Chaucer, although the sound was still that of Scotch kous, ou (ow)
being also used to denote a true diphthong (ou) in such words as
know, know, from Old English cnawan.

By returning, then, to the original values of the letters we
got the "Romic" or international (Continental) basis as opposed
to the Glosic or national basis. Thus the passage quoted above
appears as follows in Sweet’s "Broad Romic" notation:

\[
\text{Inglish glosik iz veri iiz di rihd. Wit propit triaining sfaid faj oon kudon bli redli tru too riod glosik buiks.}
\]

Another important general distinction is that between "broad"
and "narrow" systems of notation. A broad notation is one
which makes only the practically necessary distinctions in each
language, and makes them in the simplest manner possible,
omitting all that is superfluous. From a practical point of view
the necessary distinctions are those on which differences of
meaning depend. A distinction of sound which is significant
in one language may be insignificant in another. Thus the
distinction between close e and open ū, ū is significant in French,
as in pêcher, pêcher; so if in French phonetic writing the former
is denoted by (e), it is necessary to find a new symbol (e) for the open sound. But in languages such as English and German, where the short e is always open, there is no practical objection to using the unmodified (e) to denote the open sound, even if we regard (e) as the proper symbol of the close sound. And in those languages in which the short e is always open and the long e always close it is enough to mark the distinction of quantity, and leave the distinction of quality to be inferred from it (e, ee). In such a case as this it is, of course, possible to apply the principle of ignoring superfluous distinctions in the opposite way: by writing the long and short vowels in such a language (e, e), leaving the quantity to be inferred from the quality. But the former method is the more convenient, as it does not require any new letter. The “broad” principle is especially convenient in writing diphthongs. Thus in English Broad Romic we write the diphthongs in high and low with the same vowel as ask (hai, hau, aask), although all these (a)’s represent different sounds in ordinary southern English pronunciation. But the pronunciation of these diphthongs varies so much in different parts of the English-speaking territory, and the distinctions are so minute that it would be inconvenient to express them in writing; and as these distinctions are non-significant, it would be useless to do so. (ai) and (au) are symbols, not of special diphthongs, but of two classes of diphthongs: they can stand for any diphthongs which begin with a vowel resembling the Italian a, and end with approximations to i and u respectively. Theoretically it would be just as correct in English and German to write these diphthongs (ae, ao). But these notations are misleading, because they suggest simple sounds.

In comparing the sounds of a variety of languages, or of dialects of a language, and still more in dealing with sounds in general, we require a “narrow” symbol that is a minute accurate notation covering the whole field of possible sounds. It is evident from what has been said above that such a universal scientific alphabet is not suited for practical work in any one language. But the symbols of such a notation as Sweet’s “Narrow Romic” are of the greatest use as keys to the exact pronunciation of the vowels of the Broad Romic notations of each language.

To prevent confusion between these two systems of notations Broad Romic symbols are enclosed in ( ), Narrow Romic in [ ], which at the same time serve to distinguish between phonetic and nomic spellings. This in English i (i) = [i] means that the English vowel in funny is the “wide” sound, not the “narrow” one in French jini, although in the Broad Romic notations of both languages (fini) is written for funny and jini alike.

Narrow Romic was originally based on A. J. Ellis’s “Palaeotype,” in which, as the name implies, no new letters are employed. The symbols of Palaeotype are made up, as far as possible, of the letters generally accessible in printing-offices, the ordinary Roman long-case letters being supplemented by italics and small capitals (i, j, l) and turned letters (ø, ð), many digraphs (th, sh) being also used. This notation was a reaction from Ellis’s earlier phonotopy, in which a large number of new letters were used. Some of these, however, such as æ=s(h), æ=zh, were afterwards adopted into Broad and Narrow Romic. In his Palaeotype Ellis also discarded diaritical letters, which, as he rightly says, are from a typographical point of view equivalent to new letters. In Narrow Romic a certain number of diaritical letters are used, such as (ñ, á), most of which are already accessible. Palaeotype is a Roman-value notation, the main difference as regards the values of the symbols between it and the later systems being that it is more complex and arbitrary. Ellis afterwards had the unhappy idea of constructing a “Universal Glossic” on an English-values basis, which was even more cumbersome and difficult to remember than Palaeotype.

Sweet’s Romic systems were made the basis of the “International” alphabet used in Le Magasin Phonétique, which is the organ of the International Phonetic Association, directed by P. Passy. Although this system is at the present time more widely known and used than any other, and although it is constructed on the international Romic principle, it is not really an international system. It is rather an attempt to make a special adaptation of the Romic basis to the needs of the French language into a general notation for all languages. But the phonetic structure of French is so abnormal, so different from that of other languages, that the attempt to force a Broad Romic French notation on such a language as English is even more hopeless than it would be to reverse the process. Although well suited for French, this alphabet must from a wider point of view be regarded as a failure: It is too minute and rigid for practical, and yet not precise enough for scientific purposes. In short, although it has done excellent service, and has helped to clear the way for a notation which shall command general acceptance, it cannot be regarded as a final solution of the problem.

Of the numerous other notations now in use, some still adhere to the diacritic principle of Lepsius’s Standard Alphabet (1855), intended for missionary use, but found quite unfit for that purpose because of the enormous number of new types required. Most of them prefer to use new letters formed by more or less consistent modifications of the existing italic letters. A J. Lundell’s Swedish dialect alphabet and O. Jespersen’s Danish dialect alphabet are good specimens of this tendency. In the latter Roman letters are used for special distinctions, just as italic letters are used in the Romic systems.

But in spite of all diversity, there is much agreement. As regards the vowels, the following approximate values are now generally accepted:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Sound</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>as in father.</td>
</tr>
<tr>
<td>ai</td>
<td>“time.</td>
</tr>
<tr>
<td>au</td>
<td>“house.</td>
</tr>
<tr>
<td>ê</td>
<td>“beau (Fr.).</td>
</tr>
<tr>
<td>é</td>
<td>“man.</td>
</tr>
<tr>
<td>è</td>
<td>“éte (Fr.).</td>
</tr>
<tr>
<td>e</td>
<td>“oil.</td>
</tr>
<tr>
<td>ei</td>
<td>“veil.</td>
</tr>
<tr>
<td>e</td>
<td>“there.</td>
</tr>
<tr>
<td>ë</td>
<td>“further.</td>
</tr>
</tbody>
</table>

Vowel-length is in some systems denoted by doubling (aa), in others by special marks (a: &c.), the diacritic in a being used only in the nomic orthographies of dead and oriental languages.

The only consonant-symbols that require special notice are the following:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>Sound</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>as in tyul (Hung.).</td>
</tr>
<tr>
<td>n</td>
<td>as in sing.</td>
</tr>
<tr>
<td>ñ</td>
<td>as in sign.</td>
</tr>
<tr>
<td>j</td>
<td>“then.</td>
</tr>
<tr>
<td>j</td>
<td>“you.</td>
</tr>
<tr>
<td>j</td>
<td>“nagy (Hung.).</td>
</tr>
<tr>
<td>ñ</td>
<td>“ougi (Ital.).</td>
</tr>
</tbody>
</table>

All the systems of phonetic notation hitherto considered are based on the Roman alphabet. But although the Roman alphabet has many advantages from a practical point of view, it is evidently impossible to build up a consistent and systematic notation on such an inadequate foundation of arbitrary signs. What is wanted, for scientific purposes especially, is a notation independent of the Roman alphabet, built up systematically—an alphabet in which there is a definite relation between sound and symbol.

This relation may be regarded either from the organic or the acoustic point of view. The tendency of the earlier attempts at an a priori universal alphabet was to symbolize the consonants organically, the vowels acoustically, as in E. Brücke’s Phonetische Transcription (1863). It is now generally acknowledged that the vowels as well as the consonants must be represented on a strictly organic basis. This was first done in A. M. Bell’s Visible Speech (1867), which appeared again in 1882 in a shorter form and with some modifications under the title of Sounds and their Relations. Bell’s pupil, H. Sweet, gave a detailed criticism of Visible Speech in a paper on Sound-notation (Trans. of Philological Society, 1880—1881), in which he described a revised form of it called the Organic Alphabet, which he afterwards employed in his Primer of Phonetics and other works. Sweet’s Narrow Romic notation already mentioned is practically a transcription of the Organic Alphabet into Roman letters.

Such notations are alphabetic: they go on the general principle of providing separate symbols for each simple sound. But as
PHONETICS

the number of possible shades of sounds is almost infinite, even
the most minutely accurate of them can do so only within certain
limits. The Organic Alphabet especially makes a large use of
"modifiers"—characters which are added to the other symbols
to indicate nasal, palatal, &c., modifications of the sounds repres-
cented by the latter, these modifiers being generally represented
by italic letters in the Narrow Romic transcription; thus (m) =
nasalized (l).

In the Roman alphabet such symbols as f, v are arbitrary,
showing no connection in form either with one another or
with the organic actions by which they are formed; but in the
Organic symbol of v, for instance, we can see the graphic repres-
entation of its components " lips, teeth, voice-murmur." By
omitting superfluous marks and utilizing various typographical
devices the notation is so simplified that the symbols, in spite of
their minute accuracy, are often simpler than in the correspond-
ing Roman notation. The simplicity of the system is shown
by the fact that it requires only about 16o types, as compared
with the 280 of Lepsius's very imperfect Standard Alphabet.

All the systems hitherto considered are also alphabetic in
a wider sense: they are intended for continuous writing, the more
cumbrous "narrow" notations being, however, generally
employed only in writing single words or short groups. An
"alphabetic" basis was first definitely advocated by Jespersen,
who represents each sound by a group of symbols resembling a
chemical formula, each symbol representing not a sound, but
an element of a sound: the part of the palate, tongue, &c.,
where the sound is formed, the degree of separation (openness)
of the organs of speech, and so on. The two great advantages
of such a system are that it allows perfect freedom in selecting
and combining the elements and that it can be built up on the
foundation of a small number of generally accessible signs.

As regards Jespersen's scheme, it is to be regretted that he
has not worked it out in a more practical manner: that in his
choice of the thirty odd symbols that he requires should have
gone out of his way to mix up Greek with Roman letters, together
with other characters which would be avoided by any one con-
structing even a scientific alphabetic notation. And his use of
these symbols is open to much criticism. In fact, it cannot
be said that the alphabetic principle has yet had a fair trial.

The Organs of Speech.—Most speech-sounds are formed with
air expelled from the lungs (voice-bellows), which passes through
the two contractible bronchi or bronchial tubes into the also
contractible wind-pipe or trachea, on the top of which is fixed the
larynx (voice-box). Across the interior of the larynx are
stretched two elastic cords or cushions called "the vocal
chords." They are fixed in an immovable position of the larynx at one end
and at the other they are fixed to two movable cartilaginous
bodies "the arytenoids," so that the passage between them—
the glottis—can be narrowed or closed at pleasure. The glottis
is, as we see, twofold, consisting of the chord glottis and the
cartilage glottis. The two can be narrowed or closed independ-
ently. The chords can also be tightened or relaxed, lengthened
and shortened in various degrees.

When the whole glottis is wide open, no sound is produced
by the outgoing breath except that caused by the friction of
the air. Sounds in whose formation the glottis is in this
passive state are called "breath" sounds. This (/) is the
breath consonant corresponding to the "voice" or "voiced"
consonant (v). In the production of voice, the chords are
brought close enough together to be set in vibration by the air
passing between them. In the "thick" register of the voice
(chords) the chords vibrate in their whole length, in the
"thin" register or falsett only in part of their length. If the
glottis is narrowed without vibration, "whisper" is the result.
In the "weak whisper," there is narrowing the whole glottis:
in the "strong whisper," which is the ordinary form, the chord
glottis is entirely closed, so that the breath passes only through
the cartilage glottis. In what is popularly called "whisper"—
that is, speaking without voice—the breath sounds remain
unchanged, while voiced sounds substitute whisper (in the
phonetic sense) for voice.

Thus in whispering a word as feel

the (/) remains unchanged, while the following vowel and con-
sonant are formed with the glottis only half closed. Whispered
sounds—both vowels and consonants—occur in ordinary loud
speech in many languages. Thus the final consonants in such
English words as leaves, oblige are whispered, except when
followed without a pause by a voiced sound, as in obilling,
where the (3) is fully voiced.

Above the glottis—still within the larynx—comes the "upper"
or "false" glottis, by which the passage can be narrowed. On
the top of the larynx is fixed a leaf-like body, the "epiglottis,"
which in swallowing, and sometimes in speech, is pressed down
over the opening of the larynx. The contractile cavity between
the larynx and the mouth is called the "pharynx." The roof
of the mouth consists of two parts, the "soft" and the "hard
palate." The lower pendulous extremity of the soft palate,
the "uvula," in its passive state leaves the passage into the
nose open. In the formation of non-nasal sounds, such as (b),
the uvula is pressed up so as to close the passage from the
pharynx into the nose. If (b) is formed with the passage open,
it becomes the corresponding nasal consonant (m). The other
extremity of the (hard) palate is bounded by the teeth,
where between is, extending from the teeth-ridge to the arch-ridge
— the projection of the teeth-roots or alveolars.

There is great diversity among phoneticians as regards the
mapping out—the divisions—of the palate and tongue, and
their names. Foreign phoneticians generally adopt very minute
distinctions, to which they give Latin names. Bell in his
Visible Speech makes a few broad fundamental divisions.
In the arrangement adopted here (mainly based on his) sounds
formed on the soft palate are called "back," and are subdivided into
"inner" (= nearer the throat, and "outer" (= nearer the
tongue), further subdivisions being made by the terms "innermost,"
"outermost,": the position exactly half way between these two
last being defined as "middle back." Sounds formed
on the hard palate or teeth may be included under the common
term "forward," more accurately distinguished as "teeth" (dental), "gum, "front" (palatal, afterwards called "top")
by Bell), which last is really equivalent to "mid-palatal,"
including the whole of the hard palate behind the gums. All
of these divisions are further subdivided into "inner," &c.,
as with the back positions.

Of the tongue we distinguish the "back" (root), "front"
or middle, "point" (tip), and "blade," which includes the
point and the surface of the tongue immediately behind it. The
tongue can also articulate against the lips, which, again, can
articulate against the teeth. The lip passage can be closed
in various degrees. Sounds modified by lip-narrow-
ing are called "lip-modified" (labialized) or "round" (rounded),
the last being specially used in speaking of vowels.

Speech-sounds.—The most general test of a simple as opposed
to a compound sound (sound-group) is that it can be lengthened
without change. As regards place of articulation, no sound
is really simple: every sound is the result of the shape of
the whole configurative passage from the lungs to the lips; and
the ultimate sound-elements, such as voice, are never heard isolated.
The most indistinct voice-murmur is as much the result of the
shape of the superglottal passages as the clearest and most
distinct of the other vowels; and its organic formation is as
definite as theirs is, the only difference being that while in what
we regard as unmodified voice all the organs except the vocal
chords are in their passive, neutral positions, the other sounds
are formed by actively modifying the shape of the super-glottal
passages—by raising the tongue towards the palate, narrowing
the lips, &c.

The most important elements of speech-sounds are those which
are dependent on the shape of the glottis and of the mouth
passage respectively. It is on the relation between these two
factors that one of the oldest distinctions between sounds
is based: that of vowel and consonant. In vowels the element
of voice is the predominant one: a vowel is voice modified by
the different shapes of the superglottal passages. In consonants,
on the other hand, the state of the glottis is only secondary.
Consonants are generally the result of audible friction, as in (f), or of complete stoppage, as in (p). If the glottis is at the same time left open, as in (f, p), the consonant is a "breathy" or "voiceless" fricative; if it is narrowed enough to make the chords vibrate, as in (v, b), the consonant is "voice" or "voiced": intermediate positions producing the corresponding "whispered" consonants. Vowels are characterized negatively by the absence of audible friction or stoppage: if an (i) is formed with the tongue so close to the palate as to cause buzzing, it becomes a variety of the front consonant (j). There is, of course, no difficulty in forming a vowel with the glottis in the position for breath and whisper. Thus breath (i) may often be heard in French in such words as ainsî at the end of a sentence, the result being practically a weak form of the front-breath consonant (g). The division between vowel and consonant is not an absolutely definite one. As we see, the closer a vowel is—that is, the narrower its configurative passage—is the more like it is to a consonant, and the more natural it is to devocalize it. Some voice consonants, on the other hand, have so little buzz that acoustically they constitute a class between consonants and vowels—a class of "vowel-like" or "liquid" consonants, such as n, m, l.

The changes in sounds which result from active narrowing of the passages admit of an important distinction as "sound-modifying" and "sound-colouring," although the distinction is not always definite. Nasality and rounding are examples of sound-modifying processes. Thus we hear a certain resemblance between breathing and whispering. But regard all the vowels as four as distinct and practically independent sounds. Contraction of the pharynx, on the other hand, as also of the false glottis and windpipe, have only a sound-colouring effect: if a vowel is formed with such contractions its quality (timbre) is altered, but it still remains the same vowel. It follows from the definition of speech-sounds that they admit of a twofold classification: (1) organic and (2) acoustic. As already remarked, the older phoneticists used to classify the consonants organically, the vowels mainly from the acoustic point of view. The first to give an adequate organic classification of the vowels was the author of Visible Speech. Bell gave at the same time an independent acoustic classification of the consonants as well as the vowels. His acoustic classification consists simply in arranging the sounds in the order of their "pitches" (tone-heights). The pitches of the breath consonants are absolutely fixed in each individual pronunciation, while those of spoken vowels can be varied indefinitely within the compass of each voice by tightening the vocal chords in various ways and shortening their vibrating portions: the tighter and shorter the vibrating body, the quicker its vibrations, and the higher the tone. But when a vowel is whispered or breathed nothing is heard but the resonance of the configurative passages, especially in the mouth, and the pitches of these resonant cavities are as fixed as those of the breath consonants; in other words, a whispered (or breathed) vowel cannot be sung. Although the absolute pitches of voiceless sounds may vary from individual to individual the relations of the pitches are constant: thus in all pronunciations (a) and whispered (i) are the highest, breath (w) in what and whispered (u) nearly the lowest in pitch among consonants and vowels respectively.

If phonetics were an ideally perfect science there would be no occasion to discuss whether the acoustical or the organic study of the vowels and the other sound-sounds is the more important: a full description of each sound would necessarily imply (1) an exact determination of its organic formation, (2) an acoustic analysis of the sound itself, both from the objective physical point of view and from the subjective one of the impression received by the ear, and (3) an explanation of how (2) is the necessary result of (1). Even this last question has already been solved to some extent. In fact, the connection between the organic formation and the acoustic effect is often self-evident. It is evident, for instance, that (i) and (u) owe their clear sound and high pitch to their being formed by short, narrow passages in the front of the mouth, while (u) owes its low pitch to being formed in exactly the opposite way, the sound being further muffled and the pitch consequently still more lowered by the rounding.

The reason why it is impossible to classify the vowels exclusively on acoustic principles is that two vowels formed in quite different ways may have the same pitch. Thus the "high-front-round" (y) and the "high-mixed" (i) have the same pitch, the tongue-retraction of the mixed position of the latter having the same effect as the rounding of the former. It is evident, therefore, that the fundamental classification of the vowels must, like that of the consonants, be purely organic. And although for practical purposes it is often convenient to classify sounds partly from the acoustic point of view, a full scientific treatment must keep the two points of view strictly apart, and make a special chapter of the relations between them.

Vowels.—The most obvious distinction between vowels is that which depends on the share of the lips in their articulation. In such non-round vowels as (i) and (a) the lips are passive, or even separated and spread out, while in the vowels, the lips assume a clearer roundness. If, on the other hand, the lips are actively approximated, they become the round vowels (y) and (o) respectively.

Vowels are formed with different degrees of rounding. As a general rule, the narrowness of the lip-passage corresponds to the narrowness of the mouth-passage. Thus, in passing from the vowel of too to those of no and saw the back of the tongue is progressively lowered, and the rounding is diminished in the same proportion.

But there is also abnormal rounding. Thus, if we pronounce (o) with the lips in the position they have in forming (u), the resulting "over-rounded" vowel sounds half-way between (o) and (u); the second element of the diphthong (ou) in go is formed in this way. Conversely, the (u) in put is "under-rounded" in the North of England: the tongue position is kept, but the lips are only brought together a little at the corners, as in (c).

The mouth positions of the vowels are the result of two factors: (1) the height of the tongue—its nearness to the palate—and (2) the degree of its retraction. Bell distinguishes three degrees of height: in his system (u) is "high," the (o) of boy is "mid," and (a) of ago is "low." The degree of retraction: in "back" vowels, such as (u), the root of the tongue is drawn to the back of the mouth, and the whole tongue slopes down from back to front. In "front" vowels, such as (i), the front of the tongue is raised towards the hard palate, so that the tongue slopes down from front to back.

Most of these slope-positions yield vowels of a distinct and clear resonance. There is also a class of "flat" vowels, such as (a), in which the tongue is in a more or less neutral position. If the tongue were raised three-quarters of an inch from the teeth to the "high" position, we get the (i) of North Welsh dyn "man," which, as already observed, is acoustically similar to (y).

The flat vowels were called "mixed" by Bell, in accordance with his organic view of pronunciation. They are by no means a special class; and although this view is now generally abandoned, the term "mixed" is still retained by the English school of phoneticists.

In this way Bell mapped out the whole mouth by the following cardinal points:—

<table>
<thead>
<tr>
<th>Front</th>
<th>Back</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Mixed</td>
</tr>
<tr>
<td>Low</td>
<td>Mixed</td>
</tr>
</tbody>
</table>

In this arrangement "high-back," "etc., are fixed points like those of latitude and longitude. Thus normal "high" means that the tongue is raised close to the palate as is possible without causing consonantal friction, and "back" implies retraction of the same kind. The intermediate positions are defined as "raised," lowered," inner," and "outer."

The most original and at the same time the most disputed part of Bell's vowel-scheme is his distinction of "primary" and "wide." He distinguished wide vowels from the "primary" vowels: (1) the English French (i) and the corresponding English wide (i) are both high-front-vowels, and yet they are distinct in sound: the English vowel is a semitone lower in pitch. Bell explained the greater openness of the wide vowels as the result of greater expansion of the mouth; and he showed that these "primary" vowels are most nearly allied to the consonants—whence their name "primary"—the voice-passages in the formation of primary vowels being expanded only so far as to remove all fricative quality. But alterations in the position of the glottis has not been recommended, not a sound-modifying, effect; and Sweet showed that the distinction depends on the shape of the tongue, and accordingly substituted narrow" for Bell's "primary." He also showed that the distinction applies to consonants as well as vowels: thus the narrow French (w) in oui is a consonantization of the narrow French (u) in sou, while the English (w) preserves the wide quality of the (u) in put.

In forming narrow sounds there is a feeling of tension in that
part of the tongue where the sound is formed, the tongue being clenched or bunched up lengthwise, so as to be more convex than in its relaxed or "wide" condition.

The distinction between narrow and wide can often be ignored in practical phonetics, but for the purpose of a discussion of length and narrowness, shortness and wideness going together. When the distinction is marked, wide vowels may be expressed by italics, as in German (bi, na, bin).

Bell's category of "mixed-round" vowels had from the beginning been characterized by still another group of differences for the students of Visible Speech. But it was not till 1901 that Sweet showed that they are only mixed as regards position: they are really the corresponding back-round vowels moved forward into the middle of the mouth while preserving the form of the vowel. 

While it is true that they are back round vowels, they are also "back-flat" vowels: there is an exaggeration of the outer back position of such a back-round vowel as the English (a) compared with the full back (u) in German in the same word.

In the same way by moving the tongue backwards while forming a front vowel another series of "in-front" vowels is obtained. The "in-front" vowels are obtained by shifting the neutral broad positions into the full back position, keeping the tongue flat, so that these vowels might also be called "back-flat."

The out-back, in-front and in-mixed vowels are included under the common designation of "shifted," as opposed to "normal" vowels.

There is a large number of other vowel-schemes, of which a survey will be found in W. Vierot's *Elemente der Phonethik*. Many of the older ones are in the form of triangles, with the three chief vowels a, i, u at the three corners, the other vowels being inserted between these corners to fit the sides of the triangle, since the appearance of *Visible Speech* many attempts have been made to fit his new vowels into these older schemes.

In all the vowel-schemes the one now most generally known is pronounced by the e and e variants, as already mentioned. In this scheme the distinction of narrow and wide, though admitted and occasionally marked, is not an integral part of the system, the vowels being classified first as open (a, e) and closed (u, o), and within these groups as "close, "open," "half-close," "medium," "half-open" and "open."

**Consonants.**—These are the result of audible friction or stoppage, which may be accompanied either with breath, voice or whisper. Consonants admit of a two-fold division (i) by form and (ii) by place. Consonants, while by form are stop consonants, while by form are stop consonants or "stops."

If the mouth-stopping is kept, and the nose-passage is open, the stop becomes the corresponding nasal "n"; thus (b) with the soft palate as well becomes the nasal (m). In "open" consonants the sound is formed by simply narrowing the passage, as in the back-open-back (x) in Scotch and German lock. In some open consonants, such as the lip-sounds (k, g) of German fah and English fah, in which the sides of the tongue are spread out, so that the hiss of such a consonant as (k) is formed partly by the sides of the tongue and the back teeth, which gives a peculiar deep, dull quality to these sounds.

"Lip" consonants, such as (p, m), and "lip-teeth" consonants, such as (f, v), offer no difficulty. The simple lip-open-breath consonant does not occur in English; it is the sound produced in blowing out a candle. The corresponding voice sound is frequent in German—especially in Middle Germany—in such words as quelle.

If the lip-open consonants are modified by raising the back of the tongue, they become the lip-back consonants (wh, w) in English. These are also considered consonants (u) in which the sides of the tongue are spread out, so that the hiss of such a consonant as (w) is formed partly by the sides of the tongue and the back teeth, which gives a peculiar deep, dull quality to these sounds.

In a similar way consonants may be "front-modified." (i) is peculiarly susceptible to such modifications. In French and other languages it is formed with the tongue more convex than in English, and consequently with a tendency to "front-modification. From modified (s) and point (r) may be heard in Russian in such words as gusli "goose," barl "emperor," where the final vowels are silent. Some consonants are formed below the mouth.

When the glottis is sharply opened or closed on a passage of breath or voice, and at an elevated state of the glottis, is a glottal stop. This is produced in such a position, such as (k). This is a "glottal stop" is the sound produced in hiccups; and is an independent sound in some languages, such as Arabic, into which it is called "hamza. In German all words beginning with a *consonant* (e. g. das, der, die) have a more or less distinct glottal stop before the vowel. Of the passages below the glottis, the bronchial and the windpipe are both suspense of contraction.

Since the bronchial passages is the main factor in producing what is known as "the asthmatic wheeze."

If this contraction is regulated and made voluntary it results in the deep hiss of the Arabic al. If this sound is voiced, it causes a very useful voice of the same kind as that made by blowing into a horn, which is used with some speakers, especially in Germany. If this effect is softened by slightly expanding the bronchial passages, an (l)-like sound is produced, which is that of the Arabic 'ain.

Contraction of the windpipe produces a sound similar to the Arabic 'ain, but is followed by a vowel has the effect of a strong aspirate. When voiced it becomes a mere colour of the accompanying voice-murmur, or vowel, to which it imparts a deep timbre.

**Non-expiratory Sounds.**—All the sounds hitherto described imply out-breathing or expiration. Many of them can also be formed in breathing or aspiration. In English it is a not uncommon trick of speech to pronounce so in this manner, to express emphatic denial.
Some consonants are formed without either in- or out-breathing, but solely with the air in the throat or mouth. In forming "suction-stops" or "clicks" the tongue or lips are put in the position for a stop, and the air is sucked out between the organs in contact, so that there are no appreciable changes of air-pressure. Most sounds have their origin in the air rushing in to fill the vacuum. Thus the point-click is the intersection of impatience commonly written "toll". In many savage languages clicks are a part of ordinary speech.

Synthesis.—Besides analysing each sound separately, phonetics has, to deal with the phenomena which accompany synthesis or the combination of sounds. Although a sentence may consist of a single word, and that word of a single vowel, sounds mostly occur only in combination with one another. The ordinary division into sentence-syllable words is logical, not phonetic: we cannot mark off sentences and cut them up into words until we know what they mean and are able to analyse them grammatically. But the logical division into sentences corresponds to some extent with the phonetic division into "breath-groups," marked off by our inability to utter more than a certain number of syllables in succession without pausing to take breath. With each of these breath-groups there is no necessary pause between the words, except when we pause for emphasis. The only necessary phonetic divisions within the breath-group are those into syllables, sounds and intervening "glides." But before considering these last it will be necessary to say something about the general factors of synthesis: quantity, stress and intonation.

As regards quantity, it is of considerable importance for the purpose of distinguishing words. The vowel sounds are generally long, half-long, or short, in English what are called long vowels keep their full length when stressed and before final voice consonants, as in see, broad; and become half-long before voiceless consonants, as in cease, brought. In the case of vowels only, the short or half-long vowels are the only distinguishable classes of consonants. The Romance languages have short final stressed vowels, as in French si. Unstressed vowels tend to become short in most languages. The distinctions of quantity apply to consonants (stressed or unstressed), the only distinguishing classes of consonants after short stressed vowels as in man compared with German mann, where the final consonant is quite short. Consonants, like vowels, tend to become short when unstressed. But in some languages, such as Finnish and Hungarian, stress has no effect on quantity. In these languages, the same consonants occur as frequently in unstressed as in stressed syllables. Even in English we often lengthen final unstressed vowels in exclamations, as in what a pity! Some languages, such as the Russian, distinguish between the long and the short vowel sounds. No other languages have the same variety as quantity. Some languages, such as French, make comparatively little use of its distinctions, uttering all the syllables of words and sentences with a more or less even degree of force. English, on the other hand, makes great use of minute distinctions of stress both to distinguish the meanings of words and to mark their relations in sentences.

Stress is closely connected with the question of syllable-division. A syllable is a sound or sounds containing a "syllabic" or syllable-former, which is, of course, able to constitute a syllable by itself. The distinction between syllables and non-syllables depends on sonority, the more sonorous sounds being the voiced ones, while of the voiceless sounds the open (k) is the most sonorous of all the being vowels, among which, again, the openest are the most sonorous. But these differences are only relative. When a vowel and a consonant come together the sonorosity of the vowel always prevails over that of the consonant, so that the two together only constitute one syllable. But in such a word as little the second (l) is so much more sonorous than the accompanying voiceless stop that it assumes syllable function, and the whole group of letters is spoken as one syllable. The group of vowels, on the other hand, corresponds with the beginning of the stress-impulse with which it is uttered. Thus in Coke the strong stress and the second syllable begin on the (t), and in bookcase the second (k), the first (b) being voiceless, so that the (kk) is here double, not merely long, as in book (bukk) by itself.

Intonation or variation of tone (pitch) depends on the rapidity of the sound-vibrations: the more rapid the vibrations, the higher the pitch. Intonation is heard only in voiced sounds, as being the only ones capable of variations of pitch.

In singing the voice generally dwells on each note without change of pitch, and then leaps up or down to the next note as quickly as possible, so that the intervening "glide" is not noticed—except in what is called portamento. In speaking, on the other hand, the voice hardly ever dwells on any one note, but is constantly gliding upwards or downwards, so that an absolutely level tone hardly ever occurs. But in the words with gliding or falling inflections of speech we can distinguish between "voice-glides" (portaments or slurs) and "voice-leaps," although the distinction is not so definite as in singing.

The three primary forms of intonation the level tone (l) can be approximately heard in well as an expression of musing—although it really ends with a slight rise; the rising (r) in the question well?; the falling (f) in the answer yes. There are besides compound tones in which the two last in one syllable. The compound rising tone (r) may be heard in take care! the compound falling tone (s) in the sarcastic oh! All these tones may be varied according to the intervals through which they pass. The greater the interval, the greater the sonority, and consequently can only rise a little higher, expresses simple question, while the same word, if uttered with a low rise extending over an interval of between a fifth and an octave—or even more—expresses various degrees of surprise or indignation, as in the emphatic what compared with the simply interrogative what?

In English and most European languages, intonation serves to modify the general meaning and character of sentences. This is so in English. But some languages, such as Swedish and Norwegian, and Chinese, have word-intonation, by which words which would otherwise be identical in sound are distinguished. The distinction between Gr. oikoi and oikou was no doubt one of intonation.

Such a word as cat consists not only of the vowel and the two consonants of which it is made up, but also of "glides" or transitions between these sounds. The glide from the initial consonant to the vowel consists of all the intermediate positions through which the tongue passes on its way from the (k)-position to the (ae)-position. The number of these positions is infinite, but they are all implied by the mere juxtaposition of the symbols; for it is assumed that in all transitions from one position to another the shortest way is taken. Although the direction of a glide is dependent on the positions of the two fixed points between which it lies, its character may be varied both by the shape of the configurative passages—especially the glottis—and by stress and quantity.

In the word given above the "off-glides" from the consonant are both breath-glides, the glottis being kept open during the transition from the voiceless consonant to the following vowel, or, as in the case of the final consonant, to silence. The "on-glides" in the vowel to the (l) is, on the other hand, a voice-glides, the closure of the glottis being maintained till the stop is made.

In French and most of the languages of the south of Europe voiceless consonants are followed by voice-glides. Thus in French qui there is no escape of breath after the (k), as there is in English Key. Other languages again have breath on-glides before voiceless stops.

If an independent strong stress is put on the breath-glide of English key, it is heard almost as a full independent consonant, and becomes an "aspirate." Aspirated steps may be heard in the Irish-English pronunciation of such words as tell, and also in Danish, and in Sanskrit as pronounced in India. If the voice-glide after a voice stop is emphasized in a similar way the "sonant aspirates" of Sanskrit and its modern descendants are produced, as in Sanskrit dhānān.

Glides are especially important from an artistic point of view. Acoustically speaking, indeed, voiceless stops are pure glides, and the stop itself being inaudible. In voice-stops, on the other hand, the stop itself can be made audible as well as the intervening glides. In English these latter are fully voiced when they come between voice sounds, as in ago; but when preceded by voiceless sounds or by a pause, as in go! they are formed with imperfect vocality, full voice being heard only just before the stop is loosened. So also initial English (z) as in zeal is formed with imperfect vocality under the same conditions, so that it sounds like (sz). In French and other languages which have voice-glides after voiceless consonants initial (g, z) &c. are fully voiced.

Consonant-glides may be further modified in various ways. In the formation of "implosive" stops, such as occur in Saxon German, Armenian and other languages, voiceless stops followed
by voice-glides are modified by simultaneous closure of the glottis, the larynx being raised by means of its muscles, so that it acts as a plug, compressing the air between the closed glottis and the mouth-stop, so that when the latter is released a peculiar or choky effect is given to the off-glide.

Rounded glides may be heard in Russian in such words as komnata, where the rounding of the (o) is anticipated in the preceding consonant, being heard, of course, only in the off-glide of the consonant. The acoustic effect is between that of (kwo) and ordinary (ko).

 Glideless consonant-combinations remain to be considered. The general articulative principle of taking the shortest way between sounds in juxtaposition necessarily results in certain transitions being effected without any glide at all. This is regularly the case when the consonants have the same place, and differ only in form, as in (nd, dlt), where the point of the tongue remains unmoved through the whole sound-group. In such combinations as (mf) the very slight glide is often got rid of entirely by assimilating the place of the first consonant to that of the second, so that the (m) becomes a lip teeth consonant, as in English nymph.

Even when consonants are formed in different parts of the mouth it is often possible to join them without any glide. In English such combinations as (kt, pt) are glideless, the point of the tongue being brought into position before the preceding stop is loosened. In French and most other languages such consonants are separated by a breath-glide.

Combinations of stops and vowel-like consonants (tr, gl, kw) are glideless in English and most other languages. In English the breath-glide after a voiceless stop involves the beginning of the following vowel-like consonant; thus try is almost (trh-RAI).

Vowel-glides.—Vowels are begun and ended in various ways. In the "gradual beginning," which is the usual one in English and French, the glottis is gradually narrowed while breath is being emitted. The "clear" beginning the breath is kept back till the glottis is closed for voice, which begins without any breathiness." German favours the clear beginning, generally exaggerating it into a glottal stop.

In the gradual as well as the clear beginning the stress begins on the vowel itself. If in the former it is thrown back on the breath-glide, the latter is felt as an independent element and becomes the " aspirate " or (h), which in English and other languages is a glide not only in the throat but in the mouth as well, the tongue and lips practically remaining in the position for the following vowel while the glottis is being closed.

There is also a "strong" aspirate, which occurs in Finnish and other languages, in the formation of which the full vowel position is assumed from the beginning of the aspiration, which is therefore a voiceless vowel.

In most languages, when an aspirate comes between voiced sounds it is formed with imperfect vocality, the contrast of which with the full vocality of the other sounds is enough to produce the effect of breath. Thus in English behold the voice runs on without any actual break, the glottal closure being simply relaxed, not fully opened for breath, as in the emphatic aha! In some languages, such as Bohemian, this "voice-aspirate" is used everywhere, initially as well as medially.

Vowels are finished analogously, either by a gradual opening of the glottis, or by a cessation of aspiration while the glottis is still closed for voice. If stress is put on the gradual ending it becomes a diphthong aspirate, as in the Danish "visning." In such a word as manah.

Organic Basis.—Every language has certain general tendencies which control the formation of its sounds, constituting its "organic basis" or basis of articulation. The tendency of the present English is to flatten and lower the tongue and draw it back from the teeth, while the lips are kept as much as possible in a neutral position. The flattening of the tongue makes our vowels wide and favours the development of mixed vowels, and gives the dull quality which is especially noticeable in our (l); and its retraction is unfavourable to the development of teeth sounds; while the neutrality of the lips eliminates front-round vowels. In such a language as French everything is reversed. The tongue is arched, and raised, and advanced, and the lips articulate with energy. Hence French sounds tend to narrowness, dentality and distinct rounding.

National Sound-systems.—Each language uses only a part of the general phonetic material. Each one has only a limited number of sounds; and each one makes only a limited use of the synthetic distinction of quantity, stress and intonation.

As we have seen, many of these differences between individual languages are the result of, or may be referred to, differences in their organic basis.

Just as cognate languages differ from each other in phonetic structure, so also dialects of the same languages differ from each other more or less. Thus the sound-system of Lowland Scotch—which is, historically, a dialect of Northern English—differs considerably from that of standard English. Standard English itself was originally that mixture of the Midland and the Southern dialect which was spoken in London in the middle ages, just as standard French is, historically, the dialect of that district of which Paris is the centre. Standard English, like standard French, is now more a class-dialect than a local dialect: it is the language of the educated all over Great Britain. But it is not yet perfectly uniform. It is still liable to be influenced by the local dialects in grammar and vocabulary, and still more in pronunciation.

Again, English, like all other living languages, changes from generation to generation. Pronunciations which are vulgar in one century may become fashionable in the next. Sounds which are distinct in one generation may be confounded in another, and new distinctions may be made, new sounds may arise. A spoken language is, therefore, necessarily a vague and floating entity, and English is no exception to the rule.

The very fixity of which English gives all the freer play to the influences which cause change.

A standard spoken language is, strictly speaking, an abstraction. No two speakers of standard English pronounce exactly alike. And yet they all have something in common in every sound they utter. There are some divergencies, some peculiarities of pronunciation, which pass unnoticed, while others, less considerable perhaps in themselves, are at once felt as archaisms, vulgarisms or provincialisms, as the case may be, by the majority of educated speakers.

Sounds of English.—The following is a convenient classification of the vowels of standard English:

Here the vowels are in four rows: (1) normally short, or, more correctly, monophthongic, (2) long, or half-diphthongic, (3) full diphthongic, (4) monophthongic.

Those under the (1) are often strictly monosyllables such as ten, good, but they always remain absolutely monophthongic. The only one in the next row that is always strictly monophthongic is au: all the others, as we shall see, tend to become more or less diphthongic, especially in the south of England, being often exaggerated into full diphthongs of the (ai) and (au)-type in vulgar speech.

(1) (a), as in come up, is the short vowel corresponding to the (aa) in off, (au) in cough, (au) is the mid-back wide vowel, and (a) differs from it only in being narrow. Acoustically, (a) is a muffled or obscure (aa): and the same effect may be produced by advancing the tongue from the mid-back to the corresponding out-back position, preserving the wide articulation; this pronunciation of a is common in English. Out of this historical, these sounds are the result of unrounding and older (u).

(2), as in sofa, is a mixed vowel, tending to width and mid position, which occurs only unstressed. (30) in turn, earth, is low-mixed-narrow. It is the result of absorption of an older (r), weakened into (a).

(3), as in man, is low-front-wide, from older mid-back-wide.

(4) in is high-front-wide. The long (II) in eat is narrow in the north of England, while in the south it is wide (i) followed by (j).

In men is generally mid-front-wide. (e) in mane is the same vowel either narrow or wide, raised in its latter half towards (u).

In good is high-back-wide-round. Narrow (u) in toe becomes (u) in the south. (oo) in not is low back-wide-round.

The full diphthongs (ai, au, oo), as in eye, now, no, end all in lowered high vowels. Their first elements are only roughly indicated by the transcription, and vary in the mouths of different speakers. That of (ai) is generally the out-mid-back-wide, that of (au) the broader low-mixed-wide, that of (oo) the mid-back-wide-round.

The murmur-diphthongs (ai, au, oo) are in here, (e) as in str. (ii) as in
poor, all tend to broaden their first elements. That of (oa) is the low-front-narrow vowel. The other two begin with lowered forms of the wide (i) and (u) respectively. In (ua) the lowering is often carried so far as to make poor almost, or completely, into poor (paa).

The following arrangement of the English consonants will show their organic relations to one another:

\[ j \quad r \quad \eta \quad s \quad z \quad \int \quad \exists \quad \text{wh} \quad w \quad v \quad f \quad t \quad k \quad g \quad t \quad d \quad p \quad b \quad \]

The "aspirate" (h) may be regarded either as a throat-consonant or as a breath-glide.

Characteristics of the English consonant-system are the large number of hisses and buzzes, the sharp distinction of breath and voice, and, negatively, the absence of the open-back consonants, and of the voiceless forms of the vowel-like consonants (l, r) and the nasals, most of which still exist in Old English.

PHONOGRAPH (Gr. φωνή, sound, γράφειν, to write), an instrument for imprinting the vibrations of sound on a moving surface of tinfoil or wax in such a form that the original sounds can be reproduced. Much of the work that preceded or attended the experiments that were made by earlier experimenters to obtain tracings of the vibrations of bodies emitting sound, such as tuning-forks, membranes, and glass or metallic disks. In 1807 Thomas Young (Lectures, i. 191) described a method of recording the vibrations of a tuning-fork on the surface of a drum; his method was fully carried out by Wilhelm Wertheim in 1842 (Recherches sur l'élasticité, 1er mémoire). Recording the vibrations of a membrane was first accomplished by Leon Scott in 1857 by the invention of the “phonograph,” which may be regarded as the precursor of the phonograph (Comptes rendus, 33, p. 108). This instrument consisted of a thin membrane to which a delicate lever was attached. The membrane was stretched over the narrow end of an irregularly-shaped funnel or drum, while the end of the lever or marker was brought against the surface of a cylinder covered with paper on which soot had been deposited from a flame of turpentine or camphor. The cylinder was fixed on a fine screw moving horizontally when the cylinder was rotated. The marker thus described a spiral line on the blackened surface. When sounds were transmitted to the membrane and the cylinder was rotated the oscillations of the membrane were recorded. Thus sound could be obtained. This instrument was much improved by Karl Rudolph König, of Paris, who also made with it many valuable observations. (See Nature, Dec. 26, 1891, p. 184.) The mechanism of the recording lever or marker was improved by William Henry Barlow, in 1874, in an instrument called by him the “logograph” (Trans. Roy. Soc., 1874). The next step was König's invention of manometric flares by which the oscillations of a thin membrane under sound-pressure acts on a small reservoir of gas connected with a flame, and the oscillations were viewed in a rotating rectangular mirror, according to a method devised by Charles Wheatstone. Thus flame pictures of the vibrations of sound were obtained (Pogg. Ann., 1864, cxxii. 242, 600; see also Quelques expériences d'acoustique, Paris, 1852). Clarence Blake in 1876 employed the drum-head of the human ear as a logograph, and thus obtained tracings similar to those made by artificial membranes and disks (Archiv. für Ophthalmol., 1876, v. 1.). In the same year Sigmund Theodor Stein photographed the vibrations of tuning-forks, violin strings, &c. (Pogg. Ann., 1876, p. 142). Thus from Thomas Young downwards successful efforts had been made to record graphically on moving surfaces the vibrations of sounds, but the sounds so recorded could not be reproduced. This was accomplished by T. A. Edison in 1876, the first patent being dated January 1877.

In the first phonograph a spiral groove was cut on a brass drum fixed on a horizontal screw, so that when the drum was rotated it moved from right to left, as in the phonautograph. The recorder consisted of a funnel-shaped skin stretching over the end of a brass cylinder about 2 in. in diameter. In the centre of the membrane there was a stout steel needle having a chisel-shaped edge, and a stiff bit of steel spring was placed just in front of the needle near the bottom end of the spring was clamped to the edge of the brass cylinder over which the membrane was stretched. The recorder was then placed beside the large cylinder that the sharp edge of the needle ran in the middle of the spiral groove when the cylinder was rotated. The cylinder was covered with a sheet of tinfoil. During rotation of the cylinder, and while the membrane was not vibrating, the sharp edge of the marker indented the tinfoil into the spiral groove; and when the membrane was caused to vibrate by sounds being brought near the membrane, the variations of pressure corresponding to each vibration caused the marker to indentations on the tinfoil in the bottom of the groove. These indentations corresponded to the sound-waves. To reproduce the sound-waves the cylinder was removed from the tinfoil, the cylinder and the cylinder was rotated backwards until the recorder was brought to the point at which it started. The cylinder was then rotated forward so that the point of the recorder ran over the elevations and depressions of the tinfoil, and was made to vibrate by the sound-waves falling upon it, and consequently movements of the same general character but of smaller amplitude were produced, and these reproduced sound-waves. Consequently the sounds of vowels and consonants were thus accurately reproduced. The instruments were also examined by P. F. F. Grützmacher, Mayer, Graham Bell, A. M. Proctor, and Lahr (see The Telephone, The Microphone, and the Phonograph, by count du Moncel, London, 1884; also The Speaking Telephone and Talking Phonograph, by G. B. Prescott, New York, 1875).

The tinfoil phonograph, however, was an imperfect instrument, both as regards the medium on which the imprints were taken (tinfoil) and the general mechanism of the instrument. Many improvements were attempted. From 1877 to 1888 Edison was engaged in working out the details of the wax-cylinder phonograph. In 1885 A. G. Bell and S. Tainter patented the "graphophone," and in 1887, Emile Berliner, a German domiciled in America, patented the "gramophone," wherein the cylinder was coated with lampblack, and the friction between it and the stylus was made uniform for all vibrations. Incidentally it may be mentioned that Charles Cross deposited in 1877 a sealed packet with the Académie des Sciences, Paris, containing a suggestion for reproducing sound from a Scott phonautograph record. The improvements made by Edison consisted chiefly (1) in substituting for tinfoil cylinders or disks made of a waxy substance on which permanent records are taken; (2) in substituting a thin glass plate for the parchment membrane; (3) in improving the mechanical action of the marker; and (4) in driving the drum carrying the wax cylinder at a very uniform and rapid speed by an electric motor placed below the instrument. In the first place, permanent records can be taken on the wax, which is composed of stearin and paraffin. This material is brittle, but it readily takes the imprints made by the marker, which is now a tiny bit of sapphire. The marker, when used for recording, is pressed with a chisel-shaped edge of sapphire, but the sapphire is rounded when the marker is used for reproducing the sound. The marker also, instead of being a stiff needle coming from the centre of the membrane or glass plate, is now a lever, weighted so as to keep it in contact with the surface of the wax. A single vibration of a pure tone consists of an increase of pressure followed by a diminution of pressure. When the disk of glass is submitted to an increase of pressure the action of the lever is such that, while
the wax cylinder is rotating, the point of the marker is angled downwards, and this cuts deeply into the wax; and when there is diminution of pressure the point is angled upwards, so as to act less deeply. In reproducing the sound, the blunt end of the marker runs over all the elevations and depressions in the bottom of the groove cut on the wax cylinder. There is thus increased pressure transmitted upwards to the glass disk when the point runs over an elevation, and less pressure when the point runs over a depression on the wax cylinder. The glass disk is thus, as it were, pulled inwards and thrust outwards with each vibration, but these pulls and thrusts follow each other so rapidly that the ear takes no cognizance of the difference of phase of the vibrations of the glass plate in imprinting and in reproducing. The variations of pressure are communicated to the glass plate, and these, by the medium of the air, are transmitted to the drum-head of the ear, and the sound is reproduced with remarkable fidelity. It is necessary for accurate reproduction that the point of the marker lie in the centre of the groove. In the older phonographs this required accurate adjustment by a fine screw, and in addition a certain amount of lateral oscillation is allowed to the marker, by which it slips automatically into the groove. Two other improvements have been effected in the construction of the instrument. A powerful triple-spring motor has been substituted for the electric motor, and the circumference of the wax cylinder has been increased from 61 in. to 15 in., whilst the disk is 12 in. in diameter. The cylinders make about two revolutions per second, so that with the smaller cylinder the point of the marker runs over nearly 14 in. in one second, while with the larger it runs over about 30 in. The marks corresponding to the individual vibrations of tones of high pitch are therefore less likely to be crowded together with the larger cylinder, and these higher tones in particular are more accurately reproduced. In a form of instrument called the 200-thread machine motion of the drum bearing the cylinder was taken off a screw the thread of which was 50 to the inch, and by a system of gearing the grooves on the cylinder were 200 to the inch, or \( \frac{1}{125} \) of an inch apart. Thus with the large cylinder a spiral groove of over 300 yds. may be described by the recorder, and with a speed of about two revolutions per second this distance is covered by the marker in about six minutes. By diminishing the speed of revolution, which can be easily done, the time may be considerably lengthened.

In the plate machine the disk is fixed to a table which is rotated at a fixed speed of about 76 revolutions a minute. The speed of the lateral movement of the table is also uniform, and by a regular progression brings the wax blank under the sound-box to the sapphire cutting point, which detaches a fine unbroken thread of wax as it cuts into the surface of the blank to a depth of 3-4 thousandths of an inch, beginning at about half an inch from the circumference and continuing the spiral groove to within a couple of inches of the centre, according to the length of the music to be recorded. The essence difference between the disk and cylinder machine is that in the former the waves are recorded by horizontal motion over the disk, while in the latter the waves are recorded as indentations.

The following is the modus operandi of making a record. The person making the record sings or plays in front of a horn or funnel used for the purpose of focusing the sound-waves upon the diaphragm. The artist and the funnel are on one side of a screen and the recording apparatus in charge of an operator on the other. The arrangement of the various instruments in the recording room at proper relative distances from the horn is of the utmost importance in order to preserve the balance of tone. At about 4 ft. from the horn are grouped the violins and the wood wind (flutes, oboes and clarinets); behind the brass wind (horns, trumpets, trombones and tubers), and right at the back the violincolones and double basses and the kettle-drums and other instruments of percussion which may be required. On the other side of the screen is the recording cylinder or disk.

Cylinder records are duplicated by taking a plaster cast, electro-plating, and then using it as a matrix. The disk record admits of similar treatment. After dusting with graphite it is electro-plated to about 9 mm. thick. This forms the permanent or master record, from which the working negatives are made by taking wax impresses of it and obtaining copper electroplated copies in turn from them. The matrix is then nickel-plated and polished, and is ready for use in pressing out the commercial records by means of an hydraulic press, the material used being a tough and elastic substance containing shellea and other compounds such as wood charcoal, bariam sulphate, earthy colouring matters and cotton flock.

There is still a defect to be overcome in the gramophone, and that is the hissing of the needle produced by friction both during recording and intensified in reproduction. In one device for remedying this the stylus acts like a styligraphic pen, depositing on a polished surface a fine stream of some liquid which solidifies and hardens very rapidly, forming a sinuous ridge instead of a groove in a wax blank. A negative is taken of the record and the matrix is made from it in the usual way.

**Fig. 10.—Exterior of Edison Phonograph.**

**Fig. 11.—Mechanism of Edison Phonograph.**

The auxeto-gramophone or auxetophone, patented by Short in 1898 and improved by the Hon. C. A. Parsons, is similar in scope to the gramophone but attains its results in a different manner. In the Parsons-Short sound-box there is no diaphragm, but a
column of compressed air is controlled by a delicately adjusted grid-valve consisting of a metal comb rigidly connected to the stylus bar, so that as the needle moves the metal comb moves with it, following the lines of vibration fixed on the record and opening or closing the slots in the valve seat. The column of compressed air to which the valve gives access thus receives series of minute pulsations identical with those which originally produced the sounds recorded. In connexion with the sound-box is the apparatus for supplying compressed air, consisting of a six-horse power electric motor driving the compressor, an oil filter, a reservoir and a dust collector to keep the air absolutely free from foreign substances likely to interfere with the action of the valve.

The practical possibilities of the gramophone are being realized in many countries. Matrices of the records of well-known artists have been deposited at the British Museum and at the Grand Opéra in Paris. Austria established a public phonogram record office in 1903, in which are collected folk-songs and records of all kinds for enriching the department of ethnography. The same idea is being carried out in Germany by private societies and by royal museums. In Hungary records of the various dialects have been secured. The possibilities of the gramophone as a teacher are far-reaching, not only in the domain of music but in learning languages, &c.

To understand how the phonograph records and reproduces musical tones, it is necessary to remember (1) that pitch or frequency depends on the number of vibrations executed by the vibrating body in a given period of time, or on the duration of each vibration; (2) that intensity or loudness depends on the amplitude of the movement of the vibrating body; and (3) that quality, timbre or clang, first, depends on the form of the individual vibrations, or rather on the power the ear possesses of appreciating a simple pendular vibration producing a pure tone, or of decomposing more or less completely a compound vibration into the simple pendular vibrations of which it is composed. If we apply this to the record of the phonograph, we find that, given a constant and sufficiently rapid velocity of the record, a note or tone of a certain pitch will be heard when the marker runs over a number of elevations and depressions corresponding to the frequency of that note. Thus if the note was produced by 200 vibrations per second, and suppose that it lasted in the music for $\frac{1}{120}$ of a second, 20 marks, each made in $\frac{1}{120}$ of a second, would be impressed on the wax. Consequently, in reproduction, the marker would run over the 20 marks in $\frac{1}{120}$ of a second, and a tone of that frequency would be reproduced.

The loudness would correspond to the depth of each individual mark on the cylinder or the width on the disk. The greater the depth of a series of successive marks produced by a loud tone, the greater, in reproduction, would be the amplitude of the excursions of the glass disk and the louder would be the tone reproduced. Lastly, the form of the marks corresponding to individual vibrations would determine the quality of the tone or note reproduced, by which we can distinguish the tone of one instrument from another, or the sensation produced by a tone of pure and simple quality, like that from a well-bowed tuning-fork or an open organ pipe, and that given by a trumpet or an orchestra, in which the sounds of many instruments are blended together. When the phonograph records the sound of an orchestra it does not record the tones of each instrument, but it imprints the form of impression corresponding to the very complex sound-wave formed by all the instruments combined. This particular form, infinitely varied, will reproduce backwards, as has been explained, by acting on the glass plate, the particular form of sound-wave corresponding to the sound of the orchestra.

Numerous instruments blend their tones to make one wave-form, and when one instrument predominates, or if a human voice is singing to the accompaniment of the orchestra, another form of sound-wave, or rather a complex series of sound waves, is imprinted. When reproduced, the wave-forms again exist in the air as very complex variations of pressure; these act on the drum-head of the human ear, there is transmission to the brain, and there an analysis of the complex sensation takes place, and we distinguish the trombone from the oboe, or the human voice from the violin obbligato.

Many efforts have been made to obtain graphic tracings of wave-forms impressed on the wax phonograph records. Thus J. G. M’Kendrick took (1) celloidin casts of the surface, and (2) micrographs of a small portion of the cylinder (Journ. of Anat. and Phys., July 1895). He also devised a phonograph recorder by which the curves were much amplified (Trans. Roy. Soc. Edin., vol. xxxvii.; Proc. Roy. Soc. Edin., 1896-1897, Opening Address; Sound and Speech Waxes as revealed by the Phonograph, London, 1897; and Schäfer’s Physiol., vol. ii., “Vocal Sounds,” p. 1229). As already mentioned, so long ago as 1878 Fleming Jenkin and Ewing had examined the marks on the tinfoil phonograph. Professor Ludimar Hermann, of Königsberg, took up the subject about 1890, using the wax-cylinder phonograph. He obtained photographs of the curves on the wax cylinder, a beam of light reflected from a small mirror attached to the vibrating disk of the phonograph being allowed to fall on a sensitive plate while the phonograph was slowly travelling. (For references to Hermann’s important papers, see Schäfer’s Physiology, ii. 1222.) Boeke, of Alkmaar, has devised an ingenious and accurate method of obtaining curves from the wax cylinder. He measured by means of a microscope the transverse diameter of the impressions on the surface of the cylinder, on different (generally equidistant) parts of the period, and he infers
from these measurements the depth of the impressions on the same spot, or, in other words, he derives from these measurements the curve of the vibrations of the tone which produced the impression

From a communication to the Dutch Otorhinolaryngological Society Dr. Boeke has permitted the author to select the accompanying illustrations, which will give the reader a fair conception of the nature of the marks on the wax cylinder produced by various tones. Fig. 2 shows portions of the curves obtained by Hermann, and enlarged by Boeke one and a half times. The numbers 1 to 4 refer to periods of the vowel "a" (as in "hard"), sung by Hermann on the notes e e g e'. Numbers 5 to 8 show the curves of the vowel "o" (as in "go") sung to the same notes. The number of vibrations is also noted. Boeke measured the marks for the same vowels by his method, from the same cylinder, and constructing the curves, found the relative lengths to be the same. In fig. 3 we see the indentations produced by the same vowels, sung by Hermann on the notes e e g e', on the same phonograph cylinder, but delineated by Boeke after his method. The curves are also shown in linear fashion beside each group of indentations. From these measure-

ments the curves were calculated and reproduced, as in fig. 4. Thus the curves of the same vowel sounds on the same cylinder are shown by two methods, that of Hermann and that of Boeke.

In fig. 5 we see the indentations on the vowel "a", sung by Dr. Boeke, aged 55, on the notes c d e f g a b c', and near the frequencies of 128, 144, 160, 170-6, 192, 213-2, 240 and 256. The numbers 33 to 40 show the marks produced by the same vowel, sung by his son, aged 13. It will be seen that the boy sang the notes exactly an octave higher. Fig. 6 shows the marks produced by some musical sounds. Each shows on the right-hand side the curve deduced from the marks, and under it a graphical representation of the results of its harmonic analysis after the theorem of Fourier, in which the ordinates represent the amplitude of the subsequent harmonic constituents. No. 41 is the period of the sound of a pitch-pipe giving "a" (425 double vibrations per second). No. 42 is the period of a Dutch pitch-pipe, also sounding "a" (424-64 double vibrations per second). No. 43 is a record of the period of a sound produced by blowing between two strips of indiarubber to imitate the vocal cords, with a frequency of 453 double vibrations per second. No. 44 is that of a telephone pipe used by Hermann (502 double vibrations per second). Nos. 45 and 46 show the marks of a cornet sounding the notes "a" of 490 double vibrations per second, and "e" of 300 double vibrations per second. In fig. 7 are shown a number of vowel curves for the vowels o, o, a, e and i. Each curve has on the right-hand side a graphical representation of its harmonic analysis. The curves are in five vertical columns, having on the
PHONOLITE—PHORMIUM

PHONOLITE (Gr. φωη, sound, and λόθος, stone), in petrology, a group of volcanic lavas containing much nepheline and sanidine felspar. The term "clinkstone" was formerly given by geologists to many fine grained compact lavas, which split into thin tough plates, and gave out a ringing sound when struck with the hammer. Some of these clinkstones were phonolites in the modern sense, but as the name clinkstone was used for a large variety of rocks, many of which have no close affinities with one another, it has been discarded and "phonolite" is substituted for it. The group includes rocks which are rich in alkalis with only a moderate percentage of silica; hence they contain no free quartz but much alkali felspar (sanidine and anorthoclase) and nepheline. Large plates of sanidine are often visible in the rocks; the nepheline is usually not obvious to the unaided eye. Most phonolites show fluxion structure, both in the orientation of their phenocrysts and in the smaller crystals which make up the ground-mass, and this determines to a large extent the platy jointing. Although vitreous and pumiceous forms are known they are rare, and in the great majority of cases these rocks are finely crystalline with a dull or shimmering lustre in the ground-mass. Marked characteristics are the readiness with which they decompose, and the frequent occurrence of veins and cavities occupied by natrolite, leucite, scapolite and other zeolites. Small black grains of augite or hornblende and sometimes blue specks of hâtulye may be seen in the rocks when they are fresh.

The dominant minerals are sanidine, nepheline, pyroxene, amphibole, various felspathoids and iron oxides. The sanidine is usually in two generations, the first consisting of large crystals of flattened and tabular shape, while the second generation is represented by small rectangular prisms arranged in parallel streams in the ground-mass; these felspars are nearly always simply twinned on the Carlsbad plan. They contain often as much soda as potash. The nepheline takes the form of hexagonal prisms with flat ends, and may be completely replaced by fibrous zeolites, so that it can only be recognized by the outlines of its pseudomorphs. In some phonolites it is exceedingly abundant.

In the ground-mass, and these rocks form transitions to the nephelinites (nephelinolitoid phonolites) (see Petrology, Plate III, fig. 1); in others it is scarce and the rocks resemble trachytes containing a little nepheline (trachyidot phonolites). The felspathoid minerals, sodalite, hâtulye and naseen, which crystallize in isometric dodecahedra, are very frequent components of the phonolites; their presence completely invalidates the name of phono-phonolites, and their outlines may then be very irregular. Small rounded enclosures of glass are often numerous in them. The pyroxenes may be pale green diopside, dark green aegirine-augite, or blackish green aegirine (soda iron pyroxene), and in many cases are complex, the outer portions being aegirine while the centre is diopside. Fine needles of aegirine are often found in the ground-mass. The commonest hornblende is dark brown barkevice. Biotite and olivine are not really frequent in these rocks, and usually have been affected by metasomatism. The ordinary accessory minerals of igneous rocks, apatite, magnetite and zircon occur in the phonolites, and sphene is often rather common. Another mineral which is more frequent in phonolites than in many other rocks is brown melanite garnet.

The majority of the rocks of this group are of Tertiary or Recent age, but in Scotland Carboniferous phonolites occur in several localities, e.g. Traprain in Haddingtonshire, also in the Eildon Hills and in Renfrewshire. In Brazil phonolites belonging to the same age are also known. There are several districts in Europe where Tertiary or Recent phonolites occur in considerable numbers, as in Auvergne (Mont Dore), the Eifel, and Bohemia. The Wolf Rock which lies off the south coast of Cornwall, and is the site of a well-known lighthouse, is the only mass of phonolite in England; it is supposed to be the remains of a Tertiary lava or intrusion. The Canary Islands, Cape Verde Islands, Sardinia, Aden, British East Africa and New Zealand contain many types of phonolites; they are known also in New South Wales, while in the United States phonolites occur in Colorado (at Cripple Creek) and in the Black Hills of South Dakota.

Leucite is in place of nepheline in a small group of phonolites (the leucite-phonolites), known principally from Roccia Monfina and other places near Naples. Blue hâtulye is rather a conspicuous mineral in some of these rocks, and they also contain a good deal of sphene. When sanidine, nepheline and leucite all occur together in a volcanic rock it is classed among the leucitophyres (see Petrology, Plate III. fig. 2).

The chemical analyses of phonolites given below show that these rocks are very rich in alkalis and alumina with only a moderate amount of silica, while lime, magnesia and iron oxides are present only in small quantity. They have a close resemblance in these respects to the nepheline-syenites of which they provide the effusive types.

PHORCYS—PHORCUS, PHORCYN), in Greek mythology, son of Pontus (Sea) and Gaia (Earth), father of the Graeae, the Gorgons, Scylla, and Ladon (the dragon that guarded the golden apples of the Hesperides). Homer (Odyssey, vi. 240) says he is an aged sea-deity, after whom a harbour in Ithaca was named. According to Varro (quoted by Servius in Aeneid, v. 824) Phorcyx was a king of Corsica and Sardinia, who, having been defeated by King Atlas in a naval engagement in the course of which he was drowned, was subsequently worshipped as a marine divinity.

PHORMIUM, or NEW ZEALAND FLAX (also called "New Zealand hemp"), a fibre obtained from the leaves of Phormium tenax (nat. ord. Liliaceae), a native of New Zealand, the Chatham Islands and Norfolk Island. This useful plant is one of the many which were discovered by Sir Joseph Banks and Dr Solander who accompanied Captain Cook on his first voyage of discovery. The seeds brought home by Banks in 1771 did not succeed, but the plant was introduced by him to the Royal Gardens at Kew in 1798, and was there liberally distributed in Great Britain and the continent of Europe. It grows luxuriantly in the south of Ireland, where it was introduced in 1798, and also flourishes on the west coast of Scotland, and is generally cultivated as an ornamental garden plant in Europe. It has been introduced for economic purposes into the Azores and California. The name Phormium is from Gr. φορμή, a basket, in allusion to one of the uses made of its leaves by the New Zealanders.

In its native country the plant is generally found near the coast. It has a fleshy rootstock, creeping beneath the surface of the soil and sending up luxuriant tufts of narrow, sword-shaped leaves, from 4 to 8 ft. long and from 2 to 4 in. in diameter. The leaves are vertical, and arranged in two rows as in the garden flag; they are very thick, stiff and leathery, dark green above, paler below, with the margin and nerve reddish-orange. From the centre of the tuft ultimately arises a tall flower-bearing stem, 5 to 15 ft. high, bearing on its numerous
PHORONIDEA

branches a very large number of lurid red or yellow, somewhat tubular flowers, recalling those of a honeysuckle, and from 1 to 2 in. long. After flowering the plant is, however, not benefited, but increases new lateral growths from the rootstock. The plant will grow in almost any soil, but best on light rich soil, by the side of rivers and brooks, where sheltered from the wind.

Phornium has been treated as a cultivated plant in New Zealand, though only to a limited extent; for the supplies of the raw material dependence has been principally placed on the abundance of the plant in the wild, where it is planted as hedgerow and boundaries by the Maoris. Among these people the fibre has always been an article of considerable importance, yielding cloaks, mats, cordage, fishing-lines, &c., its valuable properties having attracted the attention of traders, even before colonists settled in the islands. The leaves, for fibre-yielding purposes, come to maturity in about six months, and the habit of the Maoris is to cut them down twice a year, rejecting the outer and leaving the central immature leaves. Phornium is prepared with great care by native methods. The mature fibres from the under-side of the leaves being taken. These are collected in water, scraped over the edge of a shelf so free them from adhering cellular tissue and epidermis, and more than once washed in a running stream, followed by renewed scraping till the desired purity of fibre is attained. This native process is exceedingly wasteful, not more than one-fourth of the leaf-fibre being thereby utilized. But up till 1860 it was only native-prepared phornium that was known in the market, and it was on the material so carefully, and, we believe, judiciously, selected that the reputation of the fibre was built up. The troubles with the Maoris at that period led the colonists to engage in the industry, and the sudden demand for all available fibres caused soon afterwards by the Civil War in America, rapidly stimulated their endeavours. The Maoris was invented for disintegrating the leaves and freeing the fibre, and at the same time experiments were made with the view of obtaining it by water-resembling, and by means of alkaline solutions and other chemical processes. The fibre produced by these means was of course more valuable and of course more uniform quality, and strength of the material are destroyed. The New Zealand government in 1839 offered a premium of £1750 for a machine which would treat the fibre satisfactorily, and a further £250 for a process of treating the tow; and with a view to creating further interest in the matter a member of a commission of inquiry visited England during 1897. The premium was again issued in 1899. In 1903 it was stated that a German chemist had discovered a method of working and spinning the New Zealand fibre. An idea of the value of the growth of the fibre may be gathered from the fact that the exports for 1905 amounted to 28,877 bales at a value of nearly £700,000.

Phornium is a cream-coloured fibre with a fine silky gloss, capable of being spun and woven into many of the heavier textures for which flax is used, either alone or in combination with flax. It is, however, principally a cordage fibre, and in tensile strength it is second only to manila hemp; but it does not bear well the alternative of being kept wet and dry to which hemp is subjected. The fibre has come into use as a suitable material for binder-twine as used in self-binding reaping machines.

PHORONIDEA, a zoological order, containing a single genus Phornis, which is known to be of practically world-wide distribution, while there are many records of its larva, Actinotrochus, from localities where the adult has not been found. Phornis is often gregarious, the tubes which it secretes being sometimes intertwined in an inextricable mass. These associations of individuals can hardly be the result of the metamorphosis of a corresponding number of larvae, but are probably due to a sexless adult. The development of each such fragment developing into a complete Phornis (De Selys-Longchamps). The animal is from a quarter of an inch to six inches (P. australis) in length. The free end of the long vermiform body ends in a horseshoe-shaped "lophophore," or tentacle-bearing region (fig. 1, a), which strikingly resembles that of the Phylactolaematous Polyzoa (see POLYZOA).

In some species (figs. 2, 3) the two ends of the lophophore are rolled into spirals. An oral view of this region (fig. 2) shows:

- the mouth (m), continuous on either side with the groove between the base of the tentacles; the anus (a), in the middle line, at no great distance from the mouth; a transversely elongated epistome (ep), between the mouth and the anus; and, in the concavity of the lophophore, the apertures of the nephridia (n.o.) which, according to De Selys-Longchamps, open into the two large sensory or glandular "lophophoral organs" the orifices of which are circular.

- The mouth leads into the oesophagus, which extends straight down the body nearly to the aboral end or "ampulla," where it dilates into a stomach, from which the ascending limb of the U-shaped alimentary canal passes directly to the anus. The coelomic body-cavity is divided by a transverse septum (fig. 3, s) which lies near the bases of the tentacles. The preseptal or lophophoral coelom is continued into each of the tentacles and into the epistome. The postseptal coelom is partially divided by a ventral mesentery which is attached along the entire length of the convex side of the loop of the alimentary canal (a, a²) and by two lateral mesenteries (a³) which further connect the oesophagus with the body-wall. Each nephridium is provided with either one or two funnels which open into the postseptal division of the coelom (n.e.f.). The nervous system lies in the epidermis, externally to the basement-membrane. A general nerve-plexus probably exists over considerable part of the skin, and there are special nervous concentrations in the region of the epistome and along a double crescent (N) which follows the parietal attachment of the coelomic septum. The part which lies at the base of the epistome is morphologically dorsal in position. It is said by Schultze (11) to develop, in specimens which are regenerating the lophophoral end, from an invagination of the ectoderm; and in this condition is compared by him with
an oblique septum which follows the bases of the tentacles and corresponds with that of the adult animal divides the body-cavity into two portions. The postephalic division is a coelomic space, partially subdivided by a ventral mesentery. The praephalic cavity is a vascular space, since it is in free communication with the dorsal vessel of the larva, and it persists in part as the two lophophoral vascular crescents of the adult. It contains two tufts of peculiar excretory cells, described by Goodrich (5) as "solenoidal nephridia," situated on the mesentery of the body-wall.

These pass backwards through the septum and open to the exterior ventrally. After the *Actinotrocha* has led a pelagic life for some time it develops a large ventral invagination of its body-wall (fig. 4, 2, 4V). At the metamorphosis, this sac is everted and the alimentary canal is drawn into it in the form of a loop (fig. 4, 3, 4). Most of the prætentacular region and the larval tentacles separate off, being then taken into the alimentary canal, where they are digested. The relations of the surfaces after the metamorphosis is then formed. The pouchlike aperture of the larval nephridia of *Actinotrocha* is the probable homologue of the bladder of the adult, the pouchlike aperture of the larval nephridia of *Actinotrocha* being the probable homologue of the bladder of the adult. It is probable that the pouchlike aperture of the larval nephridia of *Actinotrocha* is the probable homologue of the bladder of the adult, the pouchlike aperture of the larval nephridia of *Actinotrocha* being the probable homologue of the bladder of the adult.

The development of *Phoronis* was supposed by Caldwell (2) to furnish the explanation of the relations of the surfaces in Brachiopoda, Polyzoa, and perhaps the Sipunculoid Gephyrea, in which the ontogenetic evidence is less clear. Caldwell's views were accepted by Lankester (8) in the 9th edition of this work, the Phylum Podaxonia being there instituted to include the groups Polyzoa and Brachiopoda. The larval nephridia of the Brachiopoda was supposed to correspond with the everted ventral sac of *Actinotrocha*, but the question is complicated by the want of any complete investigation of the development of the Brachiopoda, and by the absence of the adult in the majority of the genera. There is, however, a considerable amount of resemblance between the lophophore of *Phoronis australis*, with its spirally-twisted ends, and that of a typical Brachiopod; nor do the structural details of the adult Brachiopods forbid the view that they may be related to *Phoronis*. The comparative study of the development does not support the hypothesis that the Polyzoa (q.v.) are comparable with *Phoronis*. In *Pedicellina*, the only Polyzoa in which the alimentary canal of the larva is known to be that of the first adult individual, the line between the mouth and anus is ventral in the larva, and since there is no reversal of the curvature of the digestive loop during the metamorphosis it must be regarded as ventral in the adult. There are, indeed, some similarities in the external characters of the young of the Polyzoa, and the *Phylactolaemata* Polyzoa and the *Phoronidae*, and notably between their lophophores. The supposed occurrence of a pair of nephridia in certain *Phylactolaemata*, in a position corresponding with that of the nephridia of *Phoronis*, must also be mentioned.

Although it has been maintained that the "nephridia" of *Phylactolaemata* are merely ciliated portions of the body-cavity and not indeed nephridia at all. But serious objection to the comparison is that the development of the *Phylactolaemata* is based on supposing it to be a modification of what occurs in other Polyzoa, while it appears to have no relation whatever to that of *Phoronis*.

Most observers consider that *Actinotrocha* is a highly modified Trochosphere, and this would give it some claim to be regarded as distantly related to the Entoproct Polyzoa and to other groups which have a Trochosphere larva.
Phoronis has long been regarded as a possible ally of Rhabdobranchia (see Pterobranchia); and Masterman (10) has attempted to demonstrate the existence in Actinotrocha of most of the structures which occur in the Pterobranchia. According to his view the pteroreal hood of Actinotrocha (cf. fig. 4) corresponds with the "proboscis" of Pterobranchia; the succeeding region, as far as the bases of the tentacles, with the collar; and the post-tentacular region with the metasome. Masterman's more detailed comparisons have for the most part been rejected by other morphologists. One of the most formidable difficulties in the way of the attempt to reduce Actinotrocha to the Pterobranchiate type of structure is the condition of the coelom in the former. There is indeed a perfectly definite transverse septum which divides the body-cavity in the region of the tentacle-bases. Even if it be admitted that the post-septal space may be the metasomatic cavity, the preseptal space can hardly be regarded as coelomic in nature, since it is in continuity with the proboscis-cavity. With the corresponding condition of the cavity of the pteroreal hood (the supposed proboscis-cavity) is separated from that of the supposed collar has received no confirmation. In spite of these difficulties it must be conceded that the dorsoflexure of the alimentary canal of the Pterobranchia is very Phoronis-like. It has, moreover, been shown (see especially Goodrich, 5) that shortly before its metamorphosis, Actinotrocha develops a coelomic space which lies immediately in front of the oblique septum, and gives rise later to the cavity of the lophophore and tentacles. Regarding this as a collar-cavity, it is possible to agree with Masterman that the region shown in fig. 4, i. between the tentacles and the pteroreal hood, is really a collar of which develops relatively slowly below. It will be noticed that the lophophore of Phoronis is, on this assumption, a derivative of the collar just as it is in the Pterobranchia. The epistome of the adult Phoronis cannot well be the proboscis since its cavity is continuous with the lophophore collar, and the pteroreal hood of Actinotrocha is entirely lost at the metamorphosis. It is possible that this consideration will account for the want of an anterior body-cavity in Phoronis. Since the proboscis is a purely larval organ in this genus, it may be supposed that the coelomic space which properly belongs to it fails to develop, but that the pteroreal hood itself is none the less the morphological representative of the proboscis. In spite of the criticisms which have been made on the conclusion to which Masterman has arrived, that the lophophore of Phoronis is, it is thus possible that the view is a sound one, and that the Phoronidea should take their place, with the Enteropneusta and the Pterobranchia, as an order of the Hemichordata.

PHORORHACOS, the best-known genus of the extinct Patagonian Stiercornishes (see Bird: Fossil). Among the bones found in the strata of the Santa Cruz formation (now considered as mainly of mid-Miocene date) was the piece of a mandible which F. Ameghino described in 1887 as that of an edentate mammal, under the name of Pharyrhacos longissimus (Bolet. Mus. de la Plata, l. 24). In 1891 (Rev. Argent. Hist. Nat. i. 225) these birds were at first considered as either belonging to the Ratitae, or at least related to them, until C. W. Andrews, after much of the interesting material had been acquired by the British Museum, showed the gruiform affinities of Phororhacis (Ibis, 1896, pp. 1-12), a conclusion which he was able to further corroborate after the clearing of the adherent stony matrix from the skulls (Tr. Z. S. 1901, xv. pp. 55-86, pls. 14-17). The skull of Ph. longissimus is about 2 ft. long and 10 in. high; that of Ph. inflatus is 13 in. long, and this creature is supposed to have stood only 3 ft. high at the middle of the back. The under jaw is slightly curved upwards and it contains a large foramen as for instance in Psophia and in Mysteria. The strongly hooked upper beak is very high, and very much compressed laterally. The palate is imperfectly desmognathous, as in Dicchodrillus, with an inconspicuous vomer. The quadrate has a double knob for its articulation with the skull, and basipetrogoid processes are absent. What little is known of the shoulder-girdle (breastbone still unknown) points to a flightless bird, and so do the short wing bones, although these are stout. The pelvis has an ischiadic foramen. The hind limbs are distinctly slender, the tibia of Ph. inflatus being between 15 and 16 in. length.

For further detail see F. Ameghino, "Sur les oiseaux fossiles de la Patagonie," Bolet. Inst. geogr. argentino, xv., chs. 11 and 12 (1895); F. P. Moreno and A. Mercatet, Catálogo de los pájaros fósiles de la República Argentina, An. Mus. La Plata (1891) with 21 plates.

PHOSGENITE, a rare mineral consisting of lead chlorocarbonate, (PbCl)(CO3). The tetragonal (holosymmetric) crystals are prismatic or tabular in habit, and are bounded by smooth, bright faces: they are usually colourless and transparent, and have a brilliant adamantine lustre. Sometimes the crystals have a curious helical twist about the tetrad or principal axis. The hardness is 3 and the specific gravity 3-7. The mineral is rather soft, and consequently was early known as "corneous lead" (Ger. Hornblend). The fanciful name phosgenite was given by A. Breithaupt in 1820, from phosgene, the old name of carbon oxychloride, because the mineral contains the elements carbon, oxygen and chlorine. At Cromford, near Matlock, it was long ago found in an old lead mine, being associated with anglesite and matlockite (PbCO3Cl) in cavities and decomposed calenite: hence its common name corneoflentie. Fine crystals are also found in calenite at Monteponi near Iglesias in Sardinia, but the largest are those recently found near Dundas in Tasmania. Crystals of phosgenite, and also of the corresponding bromeine compound (PbBr2CO3), have been prepared artificially.

PHOSPHATES, in chemistry, the name given to salts of phosphoric acid. As stated under Phosphorus, phosphoric oxide, PO3, combines with water in three proportions to form H3OPO4 or HPO3, metaphosphoric acid; 2H3OPO4 or H2PO3, pyrophosphoric acid; and 3H3OPO4 or H3PO4, orthophosphoric acid or ordinary phosphoric acid. These acids each give origin to several series of salts, those of ordinary phosphoric acid being the most important, and, in addition, are widely distributed in the mineral kingdom (see below under Mineral Phosphates). Orthophosphoric acid, H3PO4, a tribasic acid, is obtained by boiling a solution of the pentoxide in water; by oxidizing red phosphorus with nitric acid, or yellow phosphorus under the surface of water by bromine or iodine; and also by decomposing a mineral phosphate with sulphuric acid. It usually forms a thin syrup which on concentration in a vacuum over sulphuric acid deposits hard, transparent, rhombic prisms which melt at 45°. On long heating the syrup partly converts to pyrophosphoric and metaphosphoric acids, but on adding water and boiling the ortho-acid is re-formed. It gives origin to three classes of salts: M'H3PO4 or M'H2PO4; M'HPO3 or M'HPO4, M'2PO4, M'3PO4 or M'"PO4, wherein M', M", M'" denote a mono-, di-, and tri-valent metal. The first set may be called monometallic, the second dimetalltic, and the third trimetallic salts. Per-acid salts of the alkalis, e.g. (K2Na)H2PO4, are also known; these may be regarded as composed of a monometalllic phosphate
with phosphoric acid, thus \( M'\text{H}_{2}\text{PO}_{4} \cdot \text{H}_{2}\text{PO}_{4} \). The three principal groups differ remarkably in their behaviour towards indicators. The monomeric salts are strongly acid, the dimetrical are neutral or faintly alkaline, whilst the soluble trimeric salts are strongly alkaline. The monomeric salts of the alkalis and alkaline earths may be obtained in crystal form, but those of the heavy metals are only stable when in solution. The soluble trimeric salts are decomposed by carbonic acid into a dimetrical salt and an acid carbonate. All soluble orthophosphates give with silver nitrate a characteristic yellow precipitate of silver phosphate, \( \text{AgPO}_{4} \), soluble in ammonia and in nitric acid. Since the reaction with the acid salts is attended by liberation of nitric acid: \( \text{NaH}_{2}\text{PO}_{4} + 3\text{AgNO}_{3} = \text{AgPO}_{4} + \text{NaNO}_{3} + 2\text{HNO}_{3} \), \( \text{NaH}_{2}\text{PO}_{4} + 3\text{AgNO}_{3} = \text{AgPO}_{4} + 2\text{NaNO}_{3} + \text{HNO}_{3} \), it is necessary to neutralize the nitric acid if the complete precipitation of the phosphoric acid be desired. The three series also differ when heated: the trimeric salts, containing fixed bases are unaltered, whilst the mon- and dimetrical salts yield meta- and pyrophosphates respectively. If the heating be with charcoal, the trimeric salts of the alkalis and alkaline earths are unaltered, whilst the mono- and di-salts give free phosphorus, and a mixture of the phosphoric acid or its salts in solution are: ammonium molybdate in nitric acid, which gives on heating a canary-yellow precipitate of ammonium phosphomolybdate, \( 2\text{H}_{2}\text{O} \cdot \text{NH}_{4}\text{(NH}_{4}\text{)}_2\text{PO}_{4} \), insoluble in acids but readily soluble in ammonia; magnesium chloride, ammonium chloride and ammonia, which give on standing in a warm place a white crystalline precipitate of magnesium ammonium phosphate, \( \text{Mg(NH}_{4}\text{)}_2\text{PO}_{4} + 6\text{H}_{2}\text{O} \), which is soluble in acids but highly insoluble in ammonia solutions, and on heating to redness gives magnesium pyrophosphate, \( \text{Mg}_{3}\text{P}_{2}\text{O}_{7} \); uranic nitrate and ferric chloride, which give a yellowish-white precipitate, soluble in hydrochloric acid and ammonia, but insoluble in acetic acid; mercurous nitrate which gives a white precipitate, soluble in nitric acid, and bismuth nitrate which gives a white precipitate, insoluble in nitric acid.

**Pyrophosphoric acid, \( \text{H}_{2}\text{P}_{2}\text{O}_{7} \),** is a tetraboric acid which may be regarded as derived by eliminating a molecule of water between two molecules of ordinary phosphoric acid; its constitution may therefore be written \( \text{HO}_{3}\text{P}-\text{O}-\text{PO}(\text{OH})_{2} \). It may be obtained as a glassy mass, indistinguishable from metaphosphoric acid, by heating phosphoric acid to 215°C. When boiled with water it forms the ortho-acid, and when heated to redness the meta-acid. After neutralization, it gives a white precipitate with silver nitrate. Being a tetraboric acid it can form four classes of salts; for example, the four solium salts \( \text{Na}_{2}\text{H}_{2}\text{PO}_{4} \), \( \text{NaH}_{2}\text{PO}_{4} \), \( \text{NaH}_{2}\text{PO}_{4} \), are known. The most important is the normal salt, \( \text{Na}_{2}\text{H}_{2}\text{PO}_{4} \), which is readily obtained by heating disodium orthophosphate, \( \text{Na}_{2}\text{HPO}_{4} \). It forms monoclinic prisms (with \( 10\text{H}_{2}\text{O} \)) which are permanent in air. All soluble pyrophosphates when boiled with water for a long time are converted into orthophosphates.

**Metaphosphoric acid, \( \text{HPO}_{4} \),** is a monobasic acid which may be regarded as derived from orthophosphoric acid by the abstraction of one molecule of water, thus \( \text{H}_{2}\text{PO}_{4} - \text{H}_{2}\text{O} = \text{HPO}_{4} \); its constitution is therefore \( \text{HPO}_{4} \). The acid is formed by dissolving phosphorus pentoxide in cold water, or by strongly heating orthophosphoric acid. It forms a colourless vitreous mass, hence its name “glacial phosphoric acid.” It is readily soluble in water, boiling without change of temperature. If heated to redness, the acid, a reaction which proceeds much more rapidly on boiling. Although the acid is monobasic, salts of polymeric forms exist of the types \( \text{MPO}_{4} \), where \( n \) may be 1, 2, 3, 4, 6. They may be obtained by heating a monometallic orthophosphate of a fixed base, or a dimetrical orthophosphate of one fixed and one volatile base, e.g., microcosmic salt: \( \text{M}_{2}\text{H}_{3}\text{O}_{7} = \text{MPO}_{4} + \text{H}_{2}\text{O} \); \( \text{NH}_{4}\text{H}_{2}\text{PO}_{4} = \text{NH}_{4}\text{PO}_{4} + \text{H}_{2}\text{O} \); or \( 3\text{AgPO}_{4} + 3\text{H}_{2}\text{O} = 3\text{Ag}_{2}\text{O} + 3\text{H}_{2}\text{O} \). On heating with an oxide or carbonate they yield a trimeric orthophosphate, carbon dioxide being evolved in the latter case. Metaphosphoric acid can be distinguished from the other two acids by its power of coagulating albumen, and by not being precipitated by magnesium and ammonium chlorides in the presence of ammonia.

(C. E.)*

**Mineral Phosphates.**—These varieties of native calcium phosphate which are not distinctly crystallized, like apatite (q.v.), but occur in fibrous, compact or earthy masses, often nodular, and more or less impure, are included under the general term phosphorite. The name seems to have been given originally to the Spanish phosphorite, probably because it phosphoresced when heated. This mineral, known as Estremadura phosphate, occurs at Logrossan and Cáceres, where it forms an important deposit in clay-slate. It may contain from 55 to 62% of calcium phosphate, with about 7% of magnesium phosphate. A somewhat similar mineral, forming a fibrous incrustation, with a vitreous or amorphous surface, and containing about 9% of calcium carbonate, is known as staffelit, a name given by A. Stein in 1866 from the locality Staffel, in the valley of the Lower Lahn, where (as also in the valley of its tributary the Dill) large deposits of phosphorite occur. Dahlite is a Norwegian phosphorite, containing calcium carbonate, named in 1888 by W. C. Brügger and H. Bäckström after the Norwegian geologists T. and J. Dahl. Osteoite is a white earthy phosphorite occurring in the clefts of basaltic rocks, named in 1851 by J. C. Bromies from the Greek *arioit*, bone.

Phosphorite, when occurring in large deposits, is a mineral of much economic value for conversion into the superphosphate largely used as a fertilizing agent. Many of the impure substances thus utilized are not strictly phosphorite, but pass under such names as “rock-phosphate,” or, when nodular, as “coprolite” (q.v.), even if not of true coprolite origin. The ultimate source of these mineral phosphates may be referred to in most cases to the apatite widely distributed in crystalline rocks. As far as calcium carbonate is concerned, or the phosphoric acids it may be readily removed in solution, and may thus furnish plants and animals with the phosphates required in their structures. On the decay of these structures the phosphates are returned to the inorganic world, thus completing the cycle.

There are three sources of phosphates which are of importance geologically. They occur (a) in crystalline igneous and metamorphic rocks as an original constituent, (b) in veins associated with igneous rocks, and (c) in sedimentary rocks either as organic fragments or in secondary concretionary forms.

The first mode of occurrence is of little significance practically, for the crystalline rocks generally contain too little phosphate to be valuable, though the insoluble material may be separated and used as an inferior fertilizer. The second mode of occurrence is by the action of vauoprises emanating from cooling bodies of basic eruptive rock. Vents of this type occur at Oordegarden in Norway and Duddart in Lapland. From 1500 to 3500 tons of apatite are obtained yearly in Norway from these veins. In Ontario apatite has been worked for a long time from deposits of similar nature. The total output of Canada in 1907 was only 680 tons.

The phosphate rocks which occur among the sedimentary strata are the principal sources of phosphates for commerce and agriculture. There are two main groups: one consisting of the Cambrian, and the other of the Devonian. The soluble phosphates washed out of the guano may become fixed by entering into combination with the elements of the rock beneath. Many of the oceanic islets are composed of coral limestone, which in this
way becomes phosphatized; others are igneous, consisting of trachyte or basalt, and these rocks are also phosphatized on their surfaces but are not so valuable, inasmuch as the presence of iron or alumina in any quantity renders them unsuited for the preparation of phosphoric acid or fertilizer.

The leached guano and phosphatized rocks, which are grouped with them for commercial purposes, have been obtained in great quantities in many islands of the Pacific Ocean (such as Baker, Howland, and Kingman Islands, and the islands of Midway and W. and lat. 10° N. to 10° S. In the West Indies from Venezuela to the Bahamas and in the Caribbean Sea many islands yield supplies of leached guano; the following are important in this respect: those of the Windward and Leeward Islands, and the Netherlands Antilles; and the islands of the latitude of 10° N. and 10° S. in the Pacific Ocean have been a great source of phosphates of this type; also Jaluit Island in the Maldives Archipelago, Banaba or Ocean Island, and Nauru or Pleasant Island. On Christmas Island the phosphate has been quarried to depths of 100 ft. To these leached guanos and the phosphatized limestones the name somberrite has been given. It has been estimated that 500,000 tons of phosphate were obtained in Aruba, 1,000,000 tons from Curacao since the deposits were discovered in 1870, and Christmas Island in 1907 yielded 290,000 tons.

In the older formations the phosphates tend to become more and more mineralized by chemical processes. In whatever form they were originally deposited they often suffer complete or partial solution and are redeposited as concretionary lumps and nodules, often called coprolites. The "Challenger" and other oceanographic expeditions have shown that on the bottom of the deep sea concretions of phosphate are now gathering around the dead bodies of fishes lying in the ooze; consequently the formation of the concretions may have been carried on simultaneously with the deposition of the strata in which they occur.

Important deposits of mineral phosphates are now worked on a large scale in the United States, the annual yield far surpassing that of any other part of the world. The most active operations are carried on in Florida, where the phosphate was first worked in 1887 in the form of pebbles in the gravels of Peace River. Then followed the discovery of "hard rock-phosphate," a massive mineral, often having cavities lined with white crystalline deposits. These phosphatic limestones, and consisting of less rich phosphatic limestone, are known as "soft phosphate"; those found as smooth pebbles of variable colour are called "land pebble-phosphate," whilst the pebbles of the river-beds and old river-valleys, usually of dark colour, are distinguished as "river pebble-phosphate." The land pebble is worked in central South Florida; the hard rock chiefly between Albion and Bay City. In South Carolina, where there are important deposits of phosphate, formerly more productive than at present, the "land rock" is worked near Charleston, and the "river rock" in the Coosa river and other streams near Beaufort. The phosphate beds contain Eocene fossils derived from the underlying strata and many fragments of Pleistocene vertebrata such as mastodon, elephant, stag, horse, pig, &c. The phosphate occurs as lumps varying greatly in size, scattered through a sand or clay; they often contain phosphatized pebbles (Mollusca, &c.). Sometimes the phosphate is found at the surface, but generally it is covered by alluvial sands and clays. In 1868, and for twenty years that state was the principal producer. Then the Florida deposits began to be worked. In 1892 the phosphates of Tennessee, derived from Ordovician limestones, came into the market. From North Carolina, Alabama and Pennsylvania, also, phosphates have been obtained but only in comparatively small quantities. In 1900 mining for phosphates was commenced in Arkansas. In 1908 Florida produced 1,673,631 tons of phosphate valued at 11 million dollars. All the other states together produce less phosphate than Florida, and among them Tennessee takes the first place with an output of 403,180 tons.

Algeria contains important deposits of phosphorite, especially near Tebessa and at Tocqueville in the province of Constantine. Near Jebel Kouff, on the frontier between Algeria and Tunis, there are phosphate workings, as also in Tunis, at Gabès. The deposits belong to the Lower Eocene, where it rests unconformably upon the Cretaceous. The joint production of Tunis and Algeria in 1907 was not less than a million tons. Phosphates occur also in Egypt, in the desert east of Kenne and in the Delta basins in the vicinity of Alexandria.

France is rich in mineral phosphates, the chief deposits being the departments of the Pas-de-Calais, Somme, Aisne, Oise in and Meuse, in the north-east, and another group in the departments of Lot, Tarn-et-Garonne and Averyton, in the south-west: phosphates occur also in the Pyrenees. The deposits near Caylus and in Quercy occupy fissures and pockets in Jurassic limestone, and have yielded a remarkable assemblage of the relics of Tertiary mammals and other fossils. Phosphates occur in Belgium, especially near Mons, and these, like those of north-east France, are principally in the Upper Chalk. Two varieties of phosphate rock are recognized in these districts, viz. the phosphatic chalk and the phosphate sand, the latter resulting from the decomposition of the former. Large and valuable deposits of the sand have been obtained in sinks and depressions on the surface of the chalk. The production is on the whole diminishing in Belgium (180,000 tons in 1907), but in France it is still large (375,000 tons in 1907).

In the Lahn district and in Nassau (Germany) there are phosphate beds in Devonian rocks. The deposits were rich but irregular and local, and were much worked from 1866 to 1884, but are no longer of economic importance. In northern Estremadura in Spain and Alentejo in Portugal there are vein deposits of phosphate of lime. As much as 200,000 tons of phosphate have been raised in these provinces, but in 1906 the total production of Spain was only 1300 tons. Large deposits of phosphate occur in Russia, and those in the neighbourhood of Kertch have attracted some attention; it is said that the Cretaceous rocks, beds between the rivers Dniester and Volga contain very large deposits of phosphate, though probably of low grade.

Phosphatic nodules and concretions, with phosphatized fossils and their casts, occur at various geological horizons in Great Britain, as for example in the Eocene limestones of the Ouse beds of England, and the chalk of the Chippenham district. The Somerton Bala and the Balmes limestone in North Wales; beds of concretions occur in the Jurassic series; and important deposits are known in the Cretaceous strata, especially in the Lower Greensand and at the base of the Chalk. The Lower Greensand phosphates have been worked, under the name of "coprolites," at Potton in Bedfordshire and at Upware and Wicken in Cambridgeshire. The Cambridge Greensand, rich in phosphatic nodules, occurs at the base of the chalk at Chippenham, as at Taplow (Bucks) and Lewes (Sussex). At the base of the Red Crags in East Anglia, and occasionally at the base of the other Pliocene Crags, there is a "nodule bed" consisting of phosphatic nodules, fossil teeth and bones, some of which were formerly worked as "copro- rites" for the production of nitrate of soda. Professor R. Strutt has found that phosphatized nodules and bones are rich in radioactive constituents, and has brought this into relation with their geological age.

PHOSPHORESCENCE, a name given to a variety of physical phenomena due to different causes, but all consisting in the emission of a pale, more or less defined light, not obviously due to combustion. The word was first used by physicists to describe the property possessed by many substances of themselves becoming luminous after exposure to light. This property has been noticed from early times. Pliny speaks of various gems which shine with a light of their own, and Albertus Magnus knew that the diamond becomes phosphorescent when moderately heated. But the first discovery of this property which apparently attracted scientific attention seems to have been that of the Bologna stone (barium sulphide), which was discovered.
by Vincenzo Casciaro, a cobbler of Bologna, in about 1602. This was followed by the discovery of a number of other substances which become luminous either after exposure to light or on heating, or by attrition, and to which the general name of "phosphor" (from φῶς and φόρος, bringing light) was given. Among these may be mentioned Homberg's phosphorus (calcium chloride), John Canton's phosphorus (calcium sulphide) and Balduin's phosphorus (calcium nitrate). Of late years it has been found convenient to limit the strict meaning of the word "phosphorescence" to the case of bodies which, after exposure to light, become self-luminous (even if only for a fraction of a second). The general term "luminescence" has been proposed by E. Wiedemann to include all cases in which bodies give off light not due to ignition. This general term embraces several subdivisions. Thus, fluorescence (q.v.) and phosphorescence are included under the same heading, "photoluminescence," being distinguished from each other only by the fact that fluorescent bodies emit their characteristic light only while under the influence of the exciting illumination, while phosphorescent bodies are luminous for an appreciable time after the exciting light is cut off.

Phosphorescence, in its restricted meaning as above explained, is often distinguished from phosphorescence proper, or phosphorescence after thermal excitation, and the term "phosphorescence" is then used in a most restricted sense, as meaning phosphorescence after thermal excitation.

Phosphorescence after thermal excitation may be of two kinds, the one associated with chemical change, and the other with non-chemical change. The former, of course, is the more important, and is the kind with which we are mainly concerned here. When a substance which is capable of phosphorescence is heated, it loses much or all of the energy of excitation, and in some cases is transformed into another body. Thus, for example, strontium phosphate, heated to a high temperature, is transformed into a phosphorescent compound, strontium napthenate, which phosphoresces at a lower temperature than the original compound. When the strontium napthenate is heated, it is transformed into strontium oxide and phosphorescent carbon, and emits light at still lower temperature. This property is clearly due to the chemical change which has taken place, and is therefore termed chemical phosphorescence. In other cases the phosphorescence is due to a non-chemical change, for example, that of the sulphide of copper, which is a red, non-luminous body, and when heated to a red heat, emits a light which is only slightly visible. This kind of phosphorescence is called physical or non-chemical phosphorescence.

Chemiluminescence is the name given to those cases in which chemical action produces light without any great rise of temperature. Phosphorus exposed to moist air in a dark room shines with a soft light due to slow oxidation. Decaying wood and other vegetable substances often exhibit this property.

Electroluminescence is luminescence produced by electrical currents. Many gases are phosphorescent for a short time after an electric discharge has been passed through them, and some solid substances, especially diamonds and rubies, are strongly phosphorescent when subjected to electric currents.

See generally, Winkelmann, Handbuch der Physik, Bd. vi. (1906); E. Becquerel, La Lumière (1867).

Phosphorescence in Zoology.

The emission of light by living substance is a widespread occurrence, and is part of the general metabolism by which the potential energy introduced as food is transformed into kinetic energy and appears in the form of movement, heat, electricity and light. In many cases it is probably an accidental by-product, and like the heat radiated by living tissues, is not necessarily of use to the organism. But in other cases the capacity to produce light is awakened on stimulation, as when the wind ripples the surface of the sea, or when the water is disturbed by the blade of an oar. It has been suggested that this property of certain living substances is a protective mechanism. The light emitted by many fungi and deep-sea fish is a special property, and very elaborate mechanisms have been developed.

The late glow of phosphorescence has a certain resemblance to the light emitted by phosphorus, and it was an early suggestion that the phenomenon of living organisms was due to that substance. Phosphorus, however, and its luminous compounds are deadly poisons to all living tissues, and never occur in them in the course of natural metabolism, and the phosphorescence of life cannot therefore be assigned to the oxidation of phosphorus. On the other hand, it is certainly the result of a process of oxidation, as the emission of light continues only in the presence of oxygen. J. H. Fabre showed in 1855 that the luminous fungus, _Agaricus_, discharges more carbonic acid when it is emitting light, and Max Schultz in 1885 showed that in insects the luminous cells are closely associated with the _tracheae_, and that during phosphorescence they withdraw oxygen from them. In 1886 B. Radziwalski showed that ethereal and alcoholic alcohols emit light when slowly combined with oxygen in alkaline fumes at the appropriate temperatures. Probably the phosphorescence of organisms is due to a similar process acting on the many fats, oils and similar substances found in living cells. The colour varies much in different organisms; green has been observed in the glow-swarm, fire-flies, brite-stars, centipedes and anellids; blue in the Italian fire-fly (_Luciola italica_); blue and green light are the predominant colours in the phosphorescence of marine organisms, but red and lilac have also been observed. The Lantern-Fly (_Fulgora pyrohynchus_) is said to have a purple light, and E. H. Gibb has recorded that an individual _Appendicularia_ appeared first red, then blue, and then green. P. Panceri, chiefly in the case of _Salps_, and S. P. Langley and F. W. Very in the case of _Phyrophorus_, have investigated the light spectroscopically, and
found that it consisted of a continuous band without separate bright lines. The solar spectrum extends further both towards the violet and the red ends, but is less intense in the green when equal luminosities are compared.

Many of the bacteria of putrefaction are phosphorescent, and the light emitted by dead fish or molluscs or flesh is probably due in every case to the development of peptone. The colonies of individual bacteria appear as shining points of light. The phosphorescence of decaying wood is due to the presence of the mycelium of Acorus glaucus, and various other species of Acorus have been found to be luminous. The great mass of the sea-water are usually due to the presence of very large numbers of small luminous organisms, either protozoa or protophyta. Of these Noctiluca miliaris and species of Peridinium and Pyrocystis are the most frequent, the two former near land and the latter in mid-ocean.

In higher animals the phosphorescence tends to be limited to special parts of the body which may form elaborate and highly specialized organs. The luminous organs of such animals may become the basis of local colouration, and the whole body is henceforth a luminous organ in activity. In many cases the organs are formed by the stimulation of the pigment cells by light. The luminous organs of many of the lower forms of life are confined to the anterior end of the body. The marine copepod Calpodes is found to be luminous. In higher animals the luminous organs are usually concentrated in the thoracic appendages and the abdomen, and which were at first believed to be the organs of the fish. These deep-sea Decapod crustaceans belonging to many families are luminous. A. A. E. Holleman observed that the abdominal organs of the deep-sea fish luminous, by the light emitted from the funnel of the anterior end of the body, two small triangular patches at the entrance of the anterior siphon, and two long parallel cords within the siphon. The cells of these organs have peculiar, granulated contents. W. E. Hoyle, in his book on the sea, states that the light producing organs of cephalopods is discharged at the bases of the antennae. In most cases the luminous organs are often eye-like structures on the limbs and body.

The rock-boring mollusc, Pholas, which Pliny knew to be phosphorescent, has luminous organs on the anterior end of the mantle, two small triangular patches at the entrance of the anterior siphon, and two long parallel cords within the siphon. The cells of these organs have peculiar, granulated contents. W. E. Hoyle, in his book on the sea, states that the light producing organs of cephalopods is discharged at the bases of the antennae. In most cases the luminous organs are often eye-like structures on the limbs and body.

Some ctenophores (e.g. Geophaeus electricus and G. phosphorus) are luminous, and, if allowed to crawl over the hand, are stated to leave a luminous trail. Amongst insects, elaborate luminous organs occur in some cases. The broad and flagellate Mayfly (Telegonodes) is luminous. The so-called "glow-worm" is the larva of the fly (Bolitophila luminosa), and some grubs have been observed to be luminous, although the suggestion is that by the time the worm is proceeded from the body perhaps the luminous organs have disappeared. An aem (Oryx) and a podurra (Anurophorus) are occasionally luminous. The so-called lantern flies are Homoptera allied to the Cicadas, and the supposed luminous organ is a small head, regarded as the length of the body, of the head, the region of which there is no doubt. The glow-worms and true fireflies are beetles. Eggs, larvae and adults are in some cases luminous. The organs consist of a plate transparent superficial layer which gives off a feeble light sufficient to brighten the surrounding area. They are in close connection with the tracheae and the light is produced by the oxidation of a substance under the influence of the nervous system, and probably some kind of organic fat. In higher animals the phosphorescence is probably a sexual lure; in the males its function is unknown.

Phosphorescent organs known as photophores are characteristic structures in many of the deep-sea Teleost fishes and have been developed in widely different families (Somatidae, Scopelidae, Halosauridae and Acantholopidae), whilst numerous simple luminous organs have been detected in many species of Selachii. The number, distribution, and complexity of the organs vary much in different species. They are most frequent on the sides and ventral surface of the anterior part of the body and the head and are developed in the tail. The simple forms are generally arranged in rows, sometimes metamerically distributed; the more complex organs are larger and less numerous. In Opossums mirabilis there is a large luminous organ on a median barbel hanging down from the chin, others below the eyes, and one on the elongated first ray of the pectoral fin. In Sternoptyx diaphana there is one on the lower jaw, and in many species one or two below the eyes. The luminous organs of some species are associated with the gut, and in some this becomes luminous on slow oxidation. The essential part of the organ remains a collection of gland cells, and in the more complex types there are blood vessels and nerves, a protecting membrane, and a reflector or case. The outside, and probably the colour of the light varies with the species, these organs may serve as recognition marks. They may also attract prey, and from their association with the eyes in such a position as to send light downwards and forwards it is probable that in the higher types they are used by the fish actually as lanterns in the dark abysses of the sea.

(P. C. M.)
PHOSPHORUS

condenser, where it is condensed. It is then cast under water. The calcium silicate remains in the furnace in the form of a liquid slag which may be run off, so that the action is practically continuous. Kaolin may with advantage be used in addition to or in part substitution for sand, because the double silicate thus formed is more fusible than the single silicate of lime. The alternating current is generally used, the action not being electrolytic. One of the special advantages of the electrical over the older process is that the distilling vessels have a longer life, owing to the fact that they are not externally heated, and so subjected to a relatively high temperature when in contact with the corrosive slag formed in the process. The Readman-Parker process (see Jour. Soc. Chem. Ind., 1891, x. 445) appears to be very generally adopted. Readman, experimenting with a Cowles furnace in Staffordshire in 1888, patented his process, and in the same year Parker and Robinson, working independently, patented a similar one. The two inventors then operated, an experimental plant was run successfully, and the patents were taken over by the leading manufacturers. With the object of obtaining a valuable by-product in place of the slag produced in the furnace, several patents (e.g. H. E. Hulme and Frank, Billaudot, Bradley and Jacobs, and others) have sought to combine the manufacture of calcium carbide and phosphorus by using only calcium phosphate and carbon, effecting direct reduction by carbon at a high temperature.

The crude phosphorus is purified by melting under water and then filtering through animal black and afterwards through chamois leather, or by treating it, when molten, with chemic acid or a mixture of potassium bichromate and sulphuric acid; this causes the impurities to rise to the surface as a scum which can be skimmed off. It is usually sent on the market in the form of sticks, which were at one time prepared by sucking the molten material up glass tubes; but the dangers to the workmen and other disadvantages of this method have led to its replacement by a continuous process, in which the phosphorus leaves the melting-pot for a pipe surrounded by water, in which it solidifies and can be removed as a continuous rod.

Properties.—When perfectly pure phosphorus is a white, transparent, waxy solid, but as usually prepared it is yellowish owing to the presence of the allotropic "red phosphorus," J. Böseken (Abs. Jour. Chem. Soc., 1907, ii. 343, 760) prepares perfectly pure phosphorus by heating the crude product with chromic acid solution, washing and drying in a vacuum, first at 40°, then at 80°. It remains colourless in vacuum tubes in the dark, but on exposure it rapidly turns yellow. At 25° to 30° C. it is soft and flexible, but it hardens when strongly cooled, and can then only be cut with difficulty. The fracture is distinctly crystalline; large crystals, either regular dodecahedra or octahedra, may be obtained by crystallization from carbon bisulphide, sulphur chloride, &c., or by sublimation. It is a non-conductor of electricity. Its density at 0° is 1.836; this regularly diminishes up to the melting-point, 44.3°, when a sudden drop occurs. Molten phosphorus is a viscous, oily, highly refractive liquid, which may be supercooled to 2° below solidification. It boils at 205°, forming a colourless vapour which just about the boiling-point correponds in density to tetrametric molecules (P4); at 350° to 370°, however, Blitz and Meyer detected dissociation into P3 molecules. Beckmann obtained P4 molecules from the boiling-point of carbon bisulphide solutions, and Hertz arrived at the same conclusion from the lowering of the freezing-point in benzene solution; E. Paternò and Nasini, however, detected dissociation. Phosphorus is nearly insoluble in water, but dissolves in carbon bisulphide, sulphur chloride, benzene and oil of turpentine.

The element is highly inflammable, taking fire in air at 34° and burning with a bright white flame and forming dense white clouds of the pentoxide; in perfectly dry air or oxygen, however, it may be distilled unchanged. H. B. Baker showing that a trace of water vapour was necessary for combination to occur. When exposed to the air a stick of phosphorus undergoes slow combustion, which is revealed by a greenish-white phosphorescence when the stick is viewed in the dark. This phenomenon was minutely studied by Boyle, who found that solutions in some essential oils (oil of cloves) showed the same character, whilst in others (oils of mace and aniseed) there was no phosphorescence. He also noticed a strong garlic-like odour, which we now know to be due to ozone. Frederick Slare noticed that the luminosity increased when the air was rarefied, an observation confirmed by Hawksbee and Homberg, and which was possibly the basis of Berzelius's theory that the luminosity depended on the volatility of the element and not on the presence of oxygen. Lampadius, however, showed that there was no phosphorescence in a Torricellian vacuum; and other experimenters proved that oxygen was essential to the process. It depends on the partial pressure of the oxygen and also on temperature. In compressed air at ordinary temperature there is no glowing, but it may be brought about by heating. In oxygen under ordinary conditions there is no phosphorescence, but if the gas be heated to 25° glowing occurs, as is also the case if the pressure be diminished or the gas diluted. It is also remarkable that many gases and vapours, e.g. Cl, Br, I, N2, NO, NO2, H2S, SO2, CO2, CH4, C2H4, inhibit the phosphorescence.

An order of this action is not settled. It is certain that the formation of hydrogen peroxide and ozone accompanies the glowing, and in 1848 Schönbein tried to demonstrate that it depended on the ozone. E. Jungfleisch (Comptes rendus, 1895, 140, p. 444) suggested that it is due to the combustion of an oxide more volatile than phosphorus, a view which appears to be supported by the observations of Scharf (Zeit. physik. Chem., 1908, 62, p. 178) and of L. and E. Bloch (Comptes rendus, 1908, 147, p. 842).

The element combines directly with the halogens, sulphur and selenium, and most of the metals burn in its vapour forming phosphides. When finely divided it decomposes water giving hydrogen phosphide; it also reduces sulphur and sulphuric acids, and when boiled with water gives phosphate and hypophosphorous acid; when slowly oxidized under water it yields hypophosphoric acid.

Allotropic Phosphorus.—Several allotropic forms of phosphorus have been described, and in recent years much work has been done towards settling their identities. When the ordinary form immersed in water is exposed to light, it gradually loses its transparency and becomes coated with a thin film. This substance was regarded as an allotrope, but since it is not produced in non- aerated water it is probably an oxide. More important is the so-called "red phosphorus," which is produced by heating yellow phosphorus to about 230° for 24 hours in an inert atmosphere, or in closed vessels to 300°, when the change is effected in a few minutes. E. Kopp in 1844 and B. C. Brodie in 1853 showed that a trace of iodine also expedited the change. The same form is also produced by submitting ordinary phosphorus to the silent electric discharge, to sunlight or the ultra-violet light. Since this form does not inflame until heated to above 350°, it is manufactured in large quantities for consumption in the match industry. The process consists in heating yellow phosphorus in iron pots provided with air-tight lids, which, however, bear a long pipe open to the air. A small quantity of the phosphorus combines with the oxygen in the vessel, and after this the operation is practically a continuous explosion of nitrogen with the additional safety from any risk of explosion. The product is ground under water, and any unchanged yellow form is eliminated by boiling with caustic soda, the product being then washed and dried and finally packed in tin boxes. The red variety is remarkably different from the yellow. It is a dark red microcrystalline powder, insoluble in carbon bisulphide, oil of turpentine, &c., and having a density of 2·2. It is stable to air and light, and does not combine with oxygen until heated to above 350° in air or 260° in oxygen, forming the pentoxide. It is also non-poisonous. When heated in a vacuum to 530° it sublimes, and on condensation forms microscopic needles.

Hittorf's phosphorus is another crystalline allotrope formed by heating phosphorus with lead in a sealed tube to redness, and removing the lead by boiling the product with nitric and
PHOSPHORUS

Phosphorus is a non-metallic element with the symbol P and atomic number 15. It is a greyish white, non-luminous, non-reactive, non-flammable, brittle, crystalline, and odorless solid. It has a melting point of 44.0°C and a boiling point of 280°C. Phosphorus is obtained by distillation of its red phosphorus and pentaphosphorus pentoxide. It is readily oxidized by air and water.

Phosphorus is used in the production of phosphoric acid, which is a major component in the manufacture of fertilizers. It is also used in the production of phosphorus black, which is used as a pigment in paints and in the production of phosphorus bronze, a type of brass.

Phosphorus is a conjugated polyene with an aromatic character. It is isoelectronic with benzene, and its conjugated double bonds allow it to be incorporated into organic molecules as a substitute for benzene.

The principal occurrence of phosphorus is as the mineral phosphorite, which is the main source of phosphorus in the earth's crust. It is also obtained from organic sources, such as bone meal and blood meal.

Phosphorus is a common element in biological systems, where it is found in nucleic acids, lipids, and proteins. It is also found in minerals, such as apatite, and in the earth's crust in the form of phosphates.
other oxides, when the element is burnt in a limited supply of air or in pure oxygen under reduced pressure (E. Jungfleisch, *Abs. Jour. Chem. Soc.*, 1907, ii. 761), and also when a solution of phosphorus in the trichloride or tribromide is exposed to light. It is a yellow liquid, which has a characteristic floral or apple-like smell and which becomes vitreous on exposure to air, and can be heated to 300° without decomposition. Its existence, however, has been denied by A. Stock (*Abs. Jour. Chem. Soc.*, 1916, i. 121). The oxide PO₂ was discovered by Besson (*Comptes rendus*, 1911, i. 121). It is prepared by the reaction of phosphonium bromide and phosphorus oxochloride in sealed tubes at 50°.

**Phosphorus oxide**, PO₃, discovered by Sage in 1777, is a product of the action of phosphorus on the oxides of the halogens. It is conveniently prepared by passing a rapid current of air over burning phosphorus contained in a combustion tube, and condensing the product in a metal condenser, from which it may be removed by heating the condenser to 50°. It is obtained in the form of a white powder which is deliquescent, and which can be obtained pure from water by removing the excess of baryta by carbon dioxide, and crystallizing the filtrate. The acid may be prepared by evaporating in a vacuum the solution obtained by decomposing the barium salt with the equivalent amount of sulphuric acid. The reaction of this acid gives phosphoric and phosphoric acids (see below).

**Phosphorus pentoxide**, PO₄, was discovered by Thorpe and Tutton by heating the product of the limited combustion of phosphorus in air, and is sublimable in a state of transparency, having a lustrous, orthorhombic crystals. They are highly deliquescent, and form with water a mixture of phosphorus and phosphoric acids: PO₃ + 3H₂O = H₃PO₃ + H₃PO₄. The vapour density at about 1400° is 230, i.e. slightly less than that required by PO₄. West, *Jour. Chem. Soc.*, 1906, i. 154.

**Phosphoric oxide**, or phosphorus pentoxide, PO₄, was discovered by Maggatz in 1741. It is a yellow, fusible, liquid, which is of sublimation forms transparent, highly lustrous, orthorhombic crystals. It is extremely deliquescent, dissolving when thrown into water, with which it combines to form phosphoric acid. It is soluble in water to about 10%, and in concentrated formaldehyde, but in methanol and ethanol it is less soluble. It is insoluble in the acids, with the exception of hydrochloric acid, and is also insoluble in it. Its density is 2.135 at 21°. Vapour density and cryoscopic determinations point to the double formula PO₄. It is comparatively stable up to 200°, but when heated in a sealed tube to 440°, it gives phosphorus and the tetroxide PO₄. The acid is unaffected by light when pure, but if phosphorus be present, even in small quantity, it turns yellow and ultimately dark red. It oxidizes on exposure to air to the pentoxide, and with a brilliant inducement, it gives the sulphuric acid, H₂SO₄. It is decomposed by cold water to form phosphoric acid; but with hot water it is energetically decomposed, giving much red phosphorus or the suboxide being formed with an explosive evolution of spontaneously inflammable hydrogen phosphide, H₂P₂O₂, and phosphoric acid. With dilute alkalies phosphites are slowly formed, but with concentrated solutions the decomposition follows the same course as with hot water. With chloride it gives phosphorus pentachloride and phosphorus acid chloride, which interact to give phosphoryl and "metaphosphoryl" bromides; iodide gives phosphorus diiodide, P₂I₄, and pentoxide, PO₅; whilst hydrochloric acid gives phosphorus acid dichloride, which, with water, forms phosphoric acid, and phosphoric acid dichloride. It combines violently with sulphur at 160° to form phosphorus pentasulphide, PO₅S₅, which forms highly lustrous tetragonal crystals which melt at 295°; it is decomposed by water into sulphuric acid and metaphosphoric acid, the latter changing on standing into orthophosphoric acid. Sulphur trioxide and sulphuric acid oxidize phosphorus pentoxide, giving the pentoxide and phosphorous acid, whilst sulphur chloride, SCl₂, gives phosphoroyl and thiophosphoryl chlorides, free sulphur and sulphur dioxide. Ammonia also reacts immediately, giving phosphorus disulphide, P(NH₃)₄, and the corresponding dithione, but the reaction is not complete, and is responsible for the carry set up in the jars of those employed in the phosphorus industries (see below). It is probable, however, that pure phosphorus oxide vapour is odourless, and the odour of phosphorus which has ordinarily perceived is that of a mixture of the oxide with ozone.

**Phosphorus tetroxide**, PO₄, was obtained by Thorpe and Tutton by heating the product of the limited combustion of phosphorus in air, and which has a sublimable, transparent, highly lustrous, orthorhombic crystals. They are highly deliquescent, and form with water a mixture of phosphorus and phosphoric acids: PO₃ + 3H₂O = H₃PO₃ + H₃PO₄. The reaction of this acid gives phosphoric and phosphoric acids (see below). West, *Jour. Chem. Soc.*, 1906, i. 154.

**Phosphoric oxide**, or phosphorus pentoxide, PO₄, was discovered by Maggatz in 1741. It is a yellow, fusible, liquid, which is of sublimation forms transparent, highly lustrous, orthorhombic crystals. It is extremely deliquescent, dissolving when thrown into water, with which it combines to form phosphoric acid. It is soluble in water to about 10%, and in concentrated formaldehyde, but in methanol and ethanol it is less soluble. It is insoluble in the acids, with the exception of hydrochloric acid, and is also insoluble in it. Its density is 2.135 at 21°. Vapour density and cryoscopic determinations point to the double formula PO₄. It is comparatively stable up to 200°, but when heated in a sealed tube to 440°, it gives phosphorus and the tetroxide PO₄. The acid is unaffected by light when pure, but if phosphorus be present, even in small quantity, it turns yellow and ultimately dark red. It oxidizes on exposure to air to the pentoxide, and with a brilliant inducement, it gives the sulphuric acid, H₂SO₄. It is decomposed by cold water to form phosphoric acid; but with hot water it is energetically decomposed, giving much red phosphorus or the suboxide being formed with an explosive evolution of spontaneously inflammable hydrogen phosphide, H₂P₂O₂, and phosphoric acid. With chloride it gives phosphorus pentachloride and phosphorus acid chloride, which interact to give phosphoryl and "metaphosphoryl" bromides; iodide gives phosphorus diiodide, P₂I₄, and pentoxide, PO₅; whilst hydrochloric acid gives phosphorus acid dichloride, which, with water, forms phosphoric acid, and phosphoric acid dichloride. It combines violently with sulphur at 160° to form phosphorus pentasulphide, PO₅S₅, which forms highly lustrous tetragonal crystals which melt at 295°; it is decomposed by water into sulphuric acid and metaphosphoric acid, the latter changing on standing into orthophosphoric acid. Sulphur trioxide and sulphuric acid oxidize phosphorus pentoxide, giving the pentoxide and phosphorous acid, whilst sulphur chloride, SCl₂, gives phosphoroyl and thiophosphoryl chlorides, free sulphur and sulphur dioxide. Ammonia also reacts immediately, giving phosphorus disulphide, P(NH₃)₄, and the corresponding dithione, but the reaction is not complete, and is responsible for the carry set up in the jars of those employed in the phosphorus industries (see below). It is probable, however, that pure phosphorus oxide vapour is odourless, and the odour of phosphorus which has ordinarily perceived is that of a mixture of the oxide with ozone.

**Phosphorus tetroxide**, PO₄, was obtained by Thorpe and Tutton by heating the product of the limited combustion of phosphorus in air, and which has a sublimable, transparent, highly lustrous, orthorhombic crystals. They are highly deliquescent, and form with water a mixture of phosphorus and phosphoric acids: PO₃ + 3H₂O = H₃PO₃ + H₃PO₄. The reaction of this acid gives phosphoric and phosphoric acids (see below). West, *Jour. Chem. Soc.*, 1906, i. 154.

482

Acids. It does not dissociate on heating as do the pentachloride and pentaboramide, thus indicating the existence of pentavalent phosphorus in a gaseous compound; dissociation, however, into the trifluoride and free fluorine may be brought about by induction sparking; and in the presence of hydrogen bromide, it combines with ammonia in the proportion 2PF₃ · 5NH₃, and with nitrogen peroxide at 10⁻⁰ in the proportion PF₃ · NO₂. Phosphorus trifluoride, PF₃Cl₃, prepared from chlorine and the trifluoride, is a pungent-
tasting, white, solid substance, it is decomposed by water into hydrogen, chlorine, and phosphoric acid. Phosphorus trifluoride (see above) is an amber-coloured liquid. Phosphoramide, PF₃S, may be obtained by dissolving 2 volumes of phosphorus trifluoride with 1 volume of water (Moissan, 1886); by heating a mixture of phosphorus (III) chloride and sulphur, Trithophosphoryl pentoxide (Thorpe and Hammly, Jour. Chem. Soc., 1889, p. 795); or from phosphorus chloride and zinc fluoride at 40⁻⁰. It is a colourless fuming gas, which liquefies under ordinary pressure at 50⁻°. If heated with water, it gives phosphoric gas, phosphorus pentoxide, and hydrogen fluoride.

Phosphorus pentoxide, PO₅, is a colourless, mobile liquid, which solidifies at a greyish solid at 50⁻°. It gives phosphoric acid when mixed with water. At 200⁻°, PO₄ solidifies to a snow-like mass. Water gives phosphoric and phosphonic acids.

The corresponding sulphur compound, thiophosphoryl fluoride, PF₃S, obtained by heating lead fluoride and sulphur pentoxide to 200⁻°, is a colourless gas, which may be condensed to a clear transparent liquid. It spontaneously ignites in air or oxygen, and when the gas is issuing from a jet into air, the flame is greenish with a faintly luminous and yellow tip; the flame is probably one of the hottest known. The condensation probably follows the equation: 

\[ SF₃PO + 2O₂ = PF₃ + SO₂ \]

Phosphorus trichloride or phosphorus chloride, PCl₃, discovered by Gay-Lussac and Thénard in 1808, is obtained by a slow distillation of ordinary phosphorus in carbon disulphide (purifying in the latter case by fractional distillation). It is a colourless, mobile liquid of specific gravity 1.6218 at 0⁻° and boiling-point 76⁻°. With chlorine it gives phosphorus pentachloride (PCl₅), with alkali metals it forms a phosphorus pentahalide, and with phosphorus pentoxide, phosphorus and sulphur, PCl₃ = SF₆ + PCl₃ + 3SO₂. Electric sparks give at first free sulphur and the trifluoride, the latter at a higher temperature splitting into the pentachloride and sulphur. With water it gives ammonium fluoride and a compound of phosphorus (NH₄)₂SF₆.

1893, 15, p. 198; 1894, 16, pp. 123, 154) has described PO(OH)NH\textsubscript{4} and PO(OH\textsubscript{2})\textsubscript{2}NH\textsubscript{3}, whilst the compound PO(OH\textsubscript{2})\textsubscript{2}NH\textsubscript{2} was obtained by Schiff (Ann., 1857, 103, p. 168) by acting with ammonia on the pentoxide. Numerous other nitrogen compounds have been obtained.

The atomic weight of phosphorus was determined by Berzelius, Pêloze, Jacquinot, Dumas, Schröter, Brodie and van der Plaat. More recent are the investigations of G. Ter Gazzarian (Compt. rend., 1909, 148, p. 1397) on hydrogen phosphate, which gave the value 36.96, and C. P. Baxter and G. Jones (Journ. Amer. Chem. Soc., 1910, 32, p. 298) on silver phosphate, which gave the value 31.04.

**Therapeutics.**—The phosphorus used in the British pharmacopoeia is obtained from calcium phosphate, and is a waxlike, non-metallic substance soluble in oils and luminous in the dark. There are various medicinal preparations. In young animals phosphorus has a remarkable influence on the growth of bone, causing a proliferation of the jelly-like masses and finally a deposit in them of true bony material. Owing to this influence it has been used in rickets and osteomalacia. Its most effective use, however, is as a nerve tonic in paralysis agitans, locomotor ataxia, impotence and nervous exhaustion. In some skin diseases such as psoriasis, chronic eczema and acne, phosphorus is very useful, the diabetes cases are improved under some of its compounds. The hypophosphites have been recommended in pulmonary affections, being said to act as free phosphorus without being irritant, and the glycerophosphates are certainly useful to stimulate metabolism. Dilute phosphoric acid is used as a gastric stimulant. It does not resemble phosphorus in its physiological action and cannot be used to replace it.

**Toxicology.**—Poisonous amounts of phosphorus are frequently taken or administered, criminally or accidentally, it being easily accessible to the public in the form of matches or of vermin pastes. They may have been swallowed several hours before symptoms of acute poisoning show themselves, with nausea and vomiting, and a burning in the oesophagus, stomach and abdomen. The important thing is to prevent the absorption of the poison, so emetics and purgatives should be given at once. Sulphate of copper, in doses of 3 to 5 gr., freely diluted and repeated every few minutes forms the harmless, black phosphide of copper, which is rapidly eliminated by the kidneys. The stomach may be washed out with warm water and then with a 2% solution of permanganate of potash, the latter solution being given. The old French oil of turpentine is the best antidote to use in phosphorus poisoning, delaying the toxic effects; but ordinary oils are not only useless but harmful. When some time has elapsed before treatment and the phosphorus has become absorbed, the organic degenerative changes cannot be easily controlled. For the chronic form of industrial poisoning in the manufacture of lucifer matches—a form of necrosis, known in England as "phossy jaw" and in France as "mal chimique," a localized inflammatory infection of the periosteum, ending with the death and exfoliation of part of the bone—see MATCH.

**PHOTIUS** (c. 820–891), patriarch of Constantinople (858–867, and 878–886). From his early years he displayed an extraordinary talent and appetite for knowledge, and as soon as he had completed his own education he began to teach with distinguished success grammar, rhetoric, divinity and philosophy. The way to public life was probably opened for him by the marriage of his brother Sergius to the princess Irene, sister of Theodora, who, upon the death of her husband Theophilus in 842, had assumed the regency of the empire. Photius became captain of the guard and first imperial secretary. His friendship and intercourse with the emperor Michael III., brought promotion to Photius.

Photius was arrested and imprisoned (Nov. 858), and upon refusing to resign his office was illegally deposed, while Photius, although a layman, received all the necessary sacerdotal orders within six days, and was installed as patriarch in his place. Photius, continuing to refuse the abdication which could alone have given Photius' elevation a semblance of legality, was treated with extreme severity. His cause was subsequently espoused by Pope Nicholas I in a manner highly offensive to the independent feeling of the Eastern Church. Photius felt himself the champion of Eastern Christianity against Latin pretensions; and when 863 Nicholas, finally reconverted and deposed him, he replied by a counter-excommunication. Meanwhile, the situation was suddenly changed by the murder of Photius' patron, Bardas, by order of the emperor Michael, who was himself assassinated by his colleague Basil in the following year (867). The fall of Photius immediately ensued; he was removed from his office and banished about the end of September 867, a few days after the accession of Basil, and Ignatius was reinstated on the 23rd of November. About 876 Photius was suddenly recalled to Constantinople and entrusted with the education of Basil's children. On the death of Ignatius, probably in October 878, Photius, after a decent show of reluctance, again filled the patriarchal throne. He then proceeded to obtain the formal recognition of the Christian world. In November 879 a synod was convened at Constantinople. The legates of Pope John VIII. attended, prepared to acknowledge Photius as legitimate patriarch, a concession for which John was much censured by Latian opinion. He stood firm, however, on the two points which had long been contested between the Eastern and Western Churches, the ecclesiastical jurisdiction over Bulgaria and the introduction of the fidei commissum clause into the creed. His success with these legates who had shown a growing facility to yield, again excommunicated Photius and thus aroused the open hostility which has never been appeased to this day. Strong in the support of the council, Photius simply ignored him. At the height of glory and success he was suddenly precipitated from his dignity by another palace revolution. After the death of Basil (886), his son and successor Leo, who had formerly been devoted to Photius, but in recent years displayed great hatred towards him, deposed him from his office and banished him to the monastery of Bordel in Armenia. From this time Photius disappears from history. No letters of this period of his life are extant, which leads to the inference that his imprisonment was severe. The precise date of his death is not known, but it is said to have occurred on the 6th of February 891.

For long after Photius's death his memory was held in no special honour by his countrymen. But when, in the crusading age, the Greek Church and state were alike in danger from Latin encroachments, Photius became a national hero, and is at present regarded as little short of a saint. To this character he has not the least pretensions; few men have so strenuously advocated; but, when every special statement to his prejudices have been rejected, he still appears on a general review of his actions worldly, crafty and unscrupulous. Yet he shows no little advantage as an ecclesiastical statesman. His firmness was heroic; his patience and prudence valuable, his energy, ability and good fortune with equal dignity; and his fall was on both occasions due to revolutions beyond his control. In erudition, literary power, and force and versatility of intellect he far surpassed every contemporary.

The most important of the works of Photius is his renowned Bibliotheca or Myriobiblon (ed. I. Bekker, 1824–1825), a collection of extracts from and abridgments of 280 volumes of classical authors usually ascribed to Celsus, which was greatly extant. The work is specially rich in extracts from historical writers. To Photius we are indebted for almost all we possess of Ctesias, Memnon, Conon, the lost books of Diodorus Siculus, and the lost works of Arrian. Greek philosophy is also very fully represented, but poetry and ancient philosophy are almost entirely ignored. It seems that he did not think it necessary to deal with those authors whom every well-educated man would naturally be familiar. The literary criticisms, generally distinct from the political and historical, are also very valuable and interesting, of which the whole is considered by some as a book of reference to facilitate the reading of old classical and sacred authors, whose language and vocabulary were out of date. The only MS. of the Lexicon is the Codex Galeanus, formerly in the possession of Thomas Gale (d. 1677), and now in the library of Trinity College, Cambridge (ed. S. A. Naber, 1864, with introduction on the authorities, critical commentary, and valuable indexes). His most important theological work is the Amphilochia, a collection of some 300 questions and answers on difficult points in Scripture, addressed to Amphilochius, archbishop of Cyzicus (ed. Sophocles Oeconomus, Athens, 1858). Other similar works are his treatise in four books
against the Manichaeans and Paulicians, and his controversy with the Latins on the Procession of the Holy Spirit. His Epistles, political and private, addressed to high church and state dignitaries, are valuable for the light they throw upon the character and ver-
satility of the writer (ed. J. Valetta, London, 1864). A large
number of his speeches and homilies have been edited by S.
Aristarches (1900). The only complete edition is Bishop Malou's
in Migne's Patrologia graec., c.c.v. R. Reifstein (Der Anfang
und Die Geschichte der Forschung, 1907) has published a hitherto unedited MS.
containing numerous fragments from various verse and prose
authors.

After the allusions in his own writings the chief contemporary
authority for the life of Photius is his bitter enemy, Niceas the
Paphlogionian, the biographer of his rival Ignatius. The standard
modern work is that of Cardinal Hergenrother, Photius, Patr.
CJenon von Constantinopel (1867—1869). As a dignitary of the Roman
Church, Cardinal Hergenrother is inevitably biased against
Photius, and his work is ecclesiastical, but his natural candour and sympathy
with intellectual eminence have made him just to the man.

Scholarship (2nd ed., 1906).

PHOTOCHEMISTRY (Gr. φως, light, and "chemistry"), in
the widest sense, the branch of chemical science which deals with
the optical properties of substances and their relationship
to chemical processes. While photochemistry is concerned with the action of light on chemical change. The first definition includes such subjects as refractive and dispersive power, colour, fluorescence, phosphorescence, optical isomerism, spectroscopy, &c.—subjects which are treated under other
headings; here we only discuss the subject matter of the narrower
definition.

Probably the earliest photochemical investigations were
associated with the darkening of certain silver salts under the
action of light, processes which were subsequently utilized in photography (q.v.). At the same time, however, it had been observed that other chemical changes were regulated by the
access of light; and the first complete study of such a problem
was made by J. W. Draper in 1843, who investigated the combi-
nation of hydrogen and chlorine to form hydrochloric acid, a
reaction which had been previously studied by Gay-Lussac and
Thénard. Draper concluded that the first action of sunlight
consisted in producing an allotrope of chlorine, which sub-
sequently combined with the hydrogen. This was denied by
Bunsen and Roscoe in 1857; and in 1887 Pringsheim suggested
that the reaction proceeded in two stages: H₂O + Cl₂ = Cl₂O + H₂,
2H₂ + Cl₂O = H₂O + 2HCl. This view demands the presence of water vapour (H. B. Baker showed that the perfectly dry gases
would not combine), and also explains the period which elapsed
before the reaction commenced (the "photochemical induction"
of Bunsen and Roscoe) as taken up by the formation of the
chlorine monoxide necessary to the second part of the reaction.
The decomposition of hydrobromic acid into hydrogen and iodine
was studied by Lemoine in 1877, who found that 80% decom-
posed after a month's exposure; he also observed that the reaction
proceeded quicker in blue vessels than in red. A broader
investigation was published by P. L. Chastaing in 1878, who
found that the red rays generally oxidized inorganic compounds,
whilst the violet reduces them, and that with organic compounds
the action was entirely oxidizing. These and other reactions
suggested the making of actinometers, or instruments for measuring
the actinic effect of light waves. The most important
employ silver salts; Eder developed a form based on the
reaction between mercuric chloride and ammonium oxalate:
2HgCl₂ + (NH₄)₂C₂O₄ = 2HgCl₂ + 2NH₄Cl + C₂O₂, the extent of
the decomposition being determined by the amount of mercurous
chloride or carbon dioxide liberated.

The article PHOTOGRAPHY (q.v.) deals with early investigations
on the chemical action of light, and we may proceed here to
modern work on organic compounds. That sunlight accelerates
the action of the halogens, chlorine and bromine, on such com-
ounds, is well known. John Davy obtained phosgene, COCl₂,
by the direct combination of chlorine and carbon monoxide in
sunlight (see Weigert, Ann. d. Phys., 1907 (iv), 24, p. 55);
chlorine combines with half its volume of methane explosively
in sunlight, whilst in diffused light it substitutes; with toluene
it gives benzyl chloride, C₅H₅CH₂Cl, in sunlight, and chlortoluene,
C₅H₅(CH₂)₂Cl, in the dark; with benzene it gives an addition
product, C₅H₅Cl₂, in sunlight, and substitutes in the dark.
Bromine deports itself similarly, substituting and forming
addition products with unsaturated compounds more readily
in sunlight. Sometimes isomerization may occur; for instance,
Wislizenus found that angelic acid gave dibromanglic acid in
the dark, and dibromtigli acid in sunlight. Many substances
decompose when exposed to sunlight; for example, alkyl iodides
darken, owing to the liberation of iodine; aliphatic acids (especi-
dally dibasic) in the presence of uranic oxide lose carbon dioxide;
polyhydric alcohols give products identical with those produced
by fermentation; whilst aliphatic ketones give a hydrocarbon
and an acid.

Among aromatic compounds, benzaldehyde gives a trimeric
and tetrameric benzaldehyde, benzoic acid and hydrobenzoin (G.
L. Ciamician and P. Silber, Atti. R. Accad. Lincei, 1909); in
alcoholic solution it gives hydrobenzoin; whilst with nitro-
benzene it is oxidized to benzoic acid, the nitrobenzene suffering
reduction to nitrosobenzene and phenyl-β-hydroxylamine; the
latter isomerizes to ortho- and para-aminophenol, which, in
turn, combine with the previously formed benzoic acid. Simi-
larly acetophenone and benzophenone in alcoholic solution give
dimethylhydrobenzoin and benzonapone. With nitro-
compounds Sach and Hilbert concluded that those containing a
CH₂ side group in the ortho position to the N-OH group were
decomposed by light. For example, ortho-nitrobenzaldehyde
in alcoholic solution gives nitrosobenzal ester and 22′ azoxybenzoic
acid, with the intermediate formation of nitrobenzaldehyd
-dieithylnolact, NO₂-C₆H₄-CH(OHC)₂H₂ (E. Bamberger and F.
Elgar, Ann. 1910, 371, p. 319). Bamberger also investigated
nitrosobenzene, obtaining azoxybenzene as chief product,
together with various azo compounds, nitrobenzene, aniline,
hydroquinone and a resin.

For the photochemistry of diazo derivatives see Ruff and Stein,
Ber., 1901, 34, p. 1668, and of the terpenes see G. L. Ciamician and
P. Silber, Ber., 1907 and 1908.

Light is also powerful in producing isomerization and poly-
merization. Isomerization chiefly appears in the formation of
stable stereo-isomers from the labile forms, and more rarely
in the formation of isomers from the mixture of isomers.
Examples as we may notice the observation of Chattaway (Journ.
Chem. Soc. 1906, 89, p. 462) that many phenylhydradrones (yellow)
change into azo compounds (red), of M. Padoa and F.
Grazioli (Atti. R. Accad. Lincei, 1909) on the β-naphthylhydradrones
(the α-compounds are not phototrophic), and of A. Senier
and F. G. Sheppard (Journ. Chem. Soc., 1909, 95, p. 1943) on
the arylidine- and naphthylidine-amines, which change from
yellow to orange on exposure to sunlight. Light need not act
in the same direction as heat (changes due to heat may be
termed thermotropic). For example, heat changes the a form of
benzyl-β-aminocrotic ester into the β form, whereas light
reverses this; similarly heat and light have reverse actions
with α-diaphenyl ethylene, CH₂-C(H₃)₂ (R. Stoerner, Ber., 1900, 42,
p. 4865); the change, however, is in the same direction with
Senier and Sheppard's compounds. With regard to polymeri-
zation we may notice the production of benzene derivatives
from acetylene and its homologues, and of tetramethylenes
from olefins.

Theory of Photochemical Action.—Although much work has been
done in the qualitative and quantitative study of photo-
chemical reactions relatively little attention has been given to
the theoretical explanation of these phenomena. That the
solution was to be found in an analogy to electrolysis was
suggested by Grothuss in 1818, who laid down: (1) only those
rays which are absorbed can produce chemical change, (2) the
action of the light is analogous to that of a voltaic cell; and he
regarded light as made up of positive and negative electricity.
The first principle received early acceptance; but the develop-
ment of the second is due to W. D. Bancroft who, in a series of
papers in the *Journal of Physical Chemistry* for 1908 and 1909, has applied it generally to the reactions under consideration. Any electrolytic action demands a certain minimum electromotive force; this, however, can be diminished by suitable depolarizers, which generally act by combining with a product of the decomposition. Similarly, in some photochemical reactions the low electromotive force of the light is sufficient to induce decomposition, but in other cases a depolarizer must be present. For example, ferric chloride in aqueous solution is unchanged by light, but in alcoholic solution reduction to ferrous chloride occurs, the liberated chloride combining with the alcohol. In the same way Bancroft showed that the solvent media employed in photographic plates act as depolarizers. The same theory explains the action of sensitizers, which may act optically or chemically. In the first case they are substances having selective absorption, and hence alter the sensitivity of the system to certain rays. In the second case there are no strong absorption bands, and the substances act by combining with the decomposition products. Bancroft applied his theory to the explanation of photochemical oxidation, and also to the chlorination and bromination of hydrocarbons. In the latter case it is supposed that the halogen produces ions; if the positive ions are in excess side chains are substituted, if the negative nucleus.

**PHOTOGRAPHY** (Gr. φῶς, light, and γράφειν, to write), the science and art of producing pictures by the action of light on chemically prepared (sensitized) plates or films.

**History.**

It would be somewhat difficult to fix a date when we now know as "photographic action" was first recorded. No doubt the tanning of the skin by the sun's rays was what was first noticed, and this is as truly the effect of solar radiation as is the darkening of the sensitive paper which is now in use in photographic printing operations. We may take it that K. W. Scheele was the first to investigate the darkening action of sunlight on silver chloride. He found that when silver chloride was exposed to the action of light beneath water there was dissolved in the fluid a substance which, on the addition of lunar caustic (silver nitrate), caused the precipitation of new silver chloride, and that on applying a solution of ammonia to the blackened chloride an insoluble residue of metallic silver was left behind. He also noticed that of the rays of the spectrum the violet most readily blackened the silver chloride. In Scheele, then, we have the first who applied combined chemical and spectrum analysis to the science of photography. In 1782 J. Senebier repeated Scheele's experiments, and found that in fifteen seconds the violet rays blackened silver chloride as much as the red rays did in twenty minutes. ¹ In 1798 Count Rumford contributed a paper to the *Philosophical Transactions* entitled "An inquiry concerning the chemical properties that have been attributed to light," in which he tried to demonstrate that all effects produced on metallic solution could be brought about by a temperature somewhat less than that of boiling water. Robert Harrup in 1802, however, conclusively showed in *Nicholson's Journal* that, at all events, salts of mercury were reduced by visible radiation and not by change of temperature.

In 1801 we come to the next decided step in the study of photographic action, when Johann Wilhelm Ritter (1776–1810) proved the existence of rays lying beyond the violet, and found that they had the power of blackening silver chloride. Such a discovery naturally gave a direction to the investigations of others, and Thomas Johann Seebeck (1779–1831) (between 1802 and 1808) and, in 1812, Jacques Étienne Bérard (1789–1869) turned their attention to this particular subject, eliciting valuable information. We need only mention two or three other cases.

¹ It may here be remarked that had he used a pure spectrum he would have observed that the red rays did not blacken the material in the slightest degree.

where the influence of light was noticed at the beginning of the 19th century. William Hyde Wollaston observed the conversion of yellow gum guiacum into a green tint by the violet rays, and the restoration of the colour by the red rays—which of both are the effect of absorption of light, the original yellow colour of the gum absorbing the violet rays, whilst the green colour to which it is changed absorbs the red rays. Sir Humphry Davy found that puce-coloured lead oxide, when damp, became red in the red rays, whilst it blackened in the violet rays, and that the green mercury oxide became red in the red rays—again an example of the necessity of absorption to effect a molecular or chemical change in a substance. U. R. T. Le Bouvier Desmorgues in 1801 observed the change effected in Prussian blue, and Carl Wilhelm Böckman noted the action of the two ends of the spectrum on phosphorus, a research which John William Draper extended farther in America at a later date.

To England belongs the honour of first producing a photograph by utilizing Scheele's observations on silver chloride. In June 1802 Thomas Wedgwood (1771–1805) published in the *Journal of the Royal Institution* the paper—"An account of a method of copying paintings upon glass and of making profiles by the agency of light upon nitrate of silver, with observations by H. Davy." He remarks that white paper or white leather moistened with a solution of silver nitrate undergoes no change when kept in a dark place, but on being exposed to the daylight it speedily changes colour, and, after passing through various shades of grey and brown, becomes at length nearly black. The alteration of colour takes place more speedily in proportion as the light is more intense.

In the direct beam of the sun two or three minutes are sufficient to produce the full effect, in the shade several hours are required, and light transmitted through different-coloured glasses acts upon it with different degrees of intensity. Thus it is found that red rays, or the common sunbeams passed through red glass, have very little action upon it; yellow and green are more efficacious, but blue and violet light produce the most decided and powerful effects.

Wedgwood goes on to describe the method of using this prepared paper by throwing shadows on it, and inventorially by what we now call "contact printing." He states that he has been unable to fix his prints, no washing being sufficient to eliminate the traces of the silver salt which occupied the unexposed or shaded portions. Davy in a note states that he has found that, though the images formed by an ordinary camera obscura were too faint to print out in the solar microscope, the images of small objects could easily be copied on such paper.

1 In comparing the effects produced by light upon muriate of silver (silver chloride) with those upon the nitrate it seemed evident that whilst the violet acted much more powerfully on the former than on the latter, the more recently discovered violet beam of light acted readily upon them when moist than when dry—a fact long ago known. Even in the twilight the colour of the moist muriate of silver, spread upon paper, slowly changed from white to faint violet; though under like circumstances the nitrate was produced upon the nitrate. . . . Nothing but a method of preventing the unshaded parts of the delineations from being coloured by exposure to the day is wanting to render this process as useful as it is elegant."

In this method of preparing the paper lies the germ of the silver-printing processes of modern times, and it was only by the subsequent work of photographers that the process known as 'silver printing' is rendered more or less successful. In the "process as useful as it is elegant" was filled up—when sodium thiosulphate (hyposulphite of soda), discovered by François Chausseier in 1799, or three years before Wedgwood published his paper, was used for making the print permanent. Here we must call attention to an important observation by Seebeck of Jena in 1810. In the *Farbenlehre* of Goethe he says—"When a spectrum produced by a properly constructed prism is thrown upon moist chloride of silver paper, if the printing be continued for from fifteen to twenty minutes, whilst a constant position of the prism is maintained by any means, we observe the following. In the violet the chloride is a reddish brown (sometimes more violet, sometimes more blue), and this coloration extends well beyond the limit of the violet; in the blue the chloride takes a clear blue tint, in the green a slightly violetish tint, and in the yellow a yellow tint. I usually found the chloride unaltered; sometimes, however, it had a light yellow tint; in the red and beyond the red it took a rose or lilac tint. This image of the spectrum shows beyond the red and the violet a region more or less light and uncoloured. This is how the decomposition of the silver chloride is seen in this region. Beyond
PHOTOGRAPHY

The brown band, . . . which was produced in the violet, the silver chloride was coloured a grey-violet for a distance of several inches. In proportion as the distance from the violet increased, the tint became lighter. Beyond the red, on the contrary, the chloride took on an olive-yellow tint for a considerable distance. When moist chloride of silver, having received the action of light for a time, is exposed to the spectrum, the blue and violet behave as above. In the yellow and red regions, on the other hand, it is found that the silver chloride becomes paler; . . . the parts acted upon by the light exhibit the yellowish-green of the chloride beyond.

This has been brought forward by J. M. Eder as being the first record we have of photographic action lending itself to production of natural colours. This observation of Seebeck was allowed to lie fallow for many years, until it was again taken up and published as a novelty.

The first to find a process of photography which gave pictures that were subsequently unaffected by light was Niépce de Niepce. His process, which he called provisionally "héliographie, dessins, et gravures," consists in coating the surface of a metallic plate with a solution of asphaltum in oil of lavender and exposing it to a camera image. He recommends that the asphaltum be powdered and the oil of lavender dropped upon it in a wine-glass, and that it be then gently heated. A polished plate is covered with this varnish, and, when dried, is ready for employment in the camera. After requisite exposure, which is very long indeed, a very faint image, requiring development, is seen; Development is effected by diluting oil of lavender with ten parts by volume of white whitedrum, and this mixture has been allowed to stand two or three days it becomes clear and is ready to be used. The plate is placed in a dish and covered with the solvent. By degrees the parts unaffected by light dissolve away, and the picture, formed of modified asphaltum, is developed. The plate is then lifted from the dish, allowed to drain, and finally freed from the remaining solvents by washing in water. Subsequently, instead of using oil of lavender as the asphaltum solvent, Niepce employed an animal oil, which gave a deeper colour and more tenacity to the surface-film.

Later, Louis Jacques Mandé Daguerre (1787–1851) and Niepce used as a solvent the brittle residue obtained from evaporating the oil of lavender dissolved in ether or alcohol—a transparent solution of a lemon-yellow colour being formed. This solution was used for covering glass or silver plates, which, when dried, could be used in the camera. The time of exposure varied somewhat in length. Daguerre remarked that "the time required to procure a photographic copy of a landscape is from seven to eight hours, but single monuments, when strongly lighted by the sun, or which are themselves very bright, can be taken in about three hours." Perhaps there is no sentence that illustrates more forcibly the advance made in photography from the days when this process was described. The ratio of three hours to 1:15 of a second is a fair estimate of the progress made since Niepce. The development was conducted by means of petroleum-vapour, which dissolved the parts not acted upon by light. As a rule silver plates seem to have been used, and occasionally glass; but it does not appear whether the latter material was chosen because an image would be projected through it or whether simply for the sake of effect. Viewed in the light of present knowledge, a more perfectly developable image in half-tone would be obtained by exposing the film through the back of the glass. The action of light on most organic matter is apparently one of oxidation. In the case of asphaltum or bitumen of Judaea the oxidation causes a hardening of the material and an insolubility in the usual solvents. Hence that surface of the film is generally hardened first which first feels the influence of light. Where half-tones exist, as in a landscape picture, the film remote from the surface first receiving the image is not acted upon at all, and remains soluble in the solvent. It is thus readily seen that, in the case of half-tone pictures, or even in copying engravings, if the action were not continued sufficiently long when the surface of the film farthest from the glass was first acted upon, the layer next the glass would in some places remain soluble, and on development would be dissolved away, carrying the top layer of hardened resinous matter with it, and thus give rise to imperfect pictures. In carbon-printing development from the back of the exposed film is absolutely essential, since it depends on the same principles as heliography, and in this the same mode of procedure is advisable.

It would appear that Niepce began his researches as early as 1814, but it was not till 1827 that he had any success worth recounting. At that date he communicated a paper to Dr Bauer of Kew, the secretary of the Royal Society of London, with a view to its publication to that society. Its publication, however, was prevented because the process, of which examples were shown, was a secret one. In an authentic MS. copy of Niepce's "Mémoire," dated "Kew, le 8 Décembre 1827," he says: "in his framed drawings made on tin the tone is too feeble, but that by the use of chemicals the tone may be darkened, and the process that Niepce was familiar with the idea of using some darkening medium even with his photographs taken on tin plates.

Daguerréotype.—We have noticed in the joint process of Daguerre and Niepce that polished silver plates were used, and we know from the latter that amongst the chemical agents tried iodine suggested itself. Iodine vapour or solution applied to a silvered plate would cause the formation of silver iodide on those parts not acted upon by light. The removal of the residual picture would leave an image formed of metallic silver, whilst the black parts of the original would be represented by the darker silver iodide. This was probably the origin of the daguerreotype process. Such observers as Niepce and Daguerre, who had formed a partnership for prosecuting their researches, would very naturally have formed silver iodide and noticed that it changed in colour when exposed to the light. With parts respectively Daguerre and Niepce played in the development of the daguerreotype will probably never be known with absolute accuracy, but in a letter from Dr Bauer to Dr J. J. Bennett, F.R.S., dated the 7th of May 1830, the former says:—

"I received a very interesting letter from Mons. Isidore Niepce, dated 12th March [about a month after the publication of the daguerreotype process], and that letter fully confirms what I suspected of Daguerre's manoeuvres with poor Niepche, but Mr Isidore observes that for the present that letter might be considered confidential."

Dr Bauer evidently knew more of "poor Niépche's" work than most people, and at that early period he clearly thought that an injustice had been done to Niepce at the hands of Daguerre. It should be remarked that Niépche de Niepce died in 1833, and a new agreement was entered into between his son Isidore Niepce and Daguerre to continue the prosecution of their researches. It appears further that Niepce communicated his process to Daguerre on the 5th of December 1829. At his death some letters from Daguerre and others were left by him in which iodine, sulphur, phosphorus, &c., are mentioned as having been used on the metal plates, and their sensitiveness to light, when thus treated, commented upon. We are thus led to believe that a great part of the success in producing the daguerreotype is due to the elder Niepce, and indeed it must have been thought so at the time, since, on the publication of this process, life-pensions of 4000 francs and 4000 francs were given to Daguerre and Isidore Niepce respectively. In point of chronology the publication of the discovery of the daguerreotype process was made subsequently to the Talbot process. It will, however, be convenient to continue the history of the daguerreotype, presuming that it was published on the 6th of February 1839, whilst Talbot's process was given to the world on the 25th of January of the same year.

Daguerréotype pictures were originally taken on silver-plated copper, and even now the silvered surface thus prepared serves better than electro-deposited silver of any thickness. An outline of the operations is as follows. A brightly-polished silver plate is sensitized by being covered, after being giữed, with a very dilute nitric acid, and a soft buff is employed to give it a brilliant polish, the slightest trace of foreign matter or stain being fatal to the production of a perfect picture. The plate, thus prepared, is ready for the iodizing operation. Small fragments of iodine are scattered over a saucer, covered with gauze. Over this the plate is placed, face downwards, resting on supports, and the vapour from the iodine is allowed to form upon it a surface of silver iodide. It is essential to note the colour of the surface-formed iodide at its several stages, the varying colours being due to interference colours.
caused by the different thicknesses of the minutely thin film of iodide. The stage of maximum sensitiveness is obtained when it is of a golden orange colour. In this state the plate is withdrawn and removed to the dark slide of the camera, ready for exposure. A plate of thick paper is laid on the plate to give an even film of iodide was to saturate a card with iodine and hold the plate a short distance above the card. Long exposures were required, varying in Paris from three to thirty minutes. The length of the exposure was evidently a matter of great importance, and the quantity of iodine in the tank in which the iodine was allowed to stand for two or three minutes until silver iodide was formed. In this state the iodide is scarcely sensitive to light, but is sensitized by brushing gallo-nitrate of silver over the surface of the plate. A sample of gallo-nitrate of silver, which has been described by Fizeau, is merely a mixture, consisting of 100 grains of silver nitrate dissolved in 2 oz. of water, to which is added one-sixth of its volume of acetic acid, and immediately before applying to the plate an equal bulk of hyposulphite of soda. The plate, after being illuminated, is then ready for exposure in the camera, and, after a short insolation, develops itself in the dark, or the development may be hastened by a fresh application of the gallo-nitrate of silver. 

The picture is then fixed by washing it in clear water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried. Here there is no mention made of hyposulphite of soda as a fixing agent, that having been first used by Sir J. Herschel in February, 1846. 

The strictly historical note it ought to be mentioned that development by means of gallic acid and silver nitrate was first known to Rev. J. B. Roade. When impressing images in the solar microscope he employed a gallic acid and iodide of silver, under which more sensitive the silver chloride paper that he was using, and he accidentally found that the image could be developed without the aid of light. The priority of the discovery was claimed by Fox Talbot, and his claim was sustained after a lawsuit, apparently on account of the extent to which the new method was employed. Talbot afterwards made many slight improvements in the process. In one of his patents he recognizes the value of the proper fixing of the photogenic drawings by hyposulphite of soda, and also the value of the paper for protecting it. 

We pass over his application of albumen to porcelain and its subsequent treatment with iodine vapour, as also his application of albumen in which silver iodide was held in suspension to a glass plate, since in this he was preceded by Niepce de St Victor in 1848. 

**Albumen Process on Glass.**—It was a decided advance when Niepce de St Victor, a nephew of Nicéphore de Niepce, employed glass plates and albumen. His process was called the daguerreotype in conjunction with iodine in 1840, and A. F. J. Claudet (1797–1867) employed a combination of iodine and chlorine vapour in 1841. In 1844 Daguerre published his improved method of preparing the plates, which is in reality based on the use of bromine with iodide. That this addition points to additional sensitiveness will be readily understood when we remark that so-called instantaneous pictures of yachts in full sail, and of large size, have been taken on plates so prepared—a feat which is utterly impossible with the original process as described by Daguerre. The next improvement in the process was to tone or gilding the image by a solution of gold, a practice introduced by H. L. Fizeau. Gold chloride is mixed with hyposulphite of soda, and the levelled plate, bearing a sufficient quantity of the fluid, is warmed by a spirit-lamp until the required vigour is given to the image, as a consequence of which it is better seen in most lights. Nearly all the daguerreotypes exhibited at the Paris exhibition of 1855 were treated in this manner, and the durable permanence is in a great measure due to this operation. Images of this class can be copied by taking electrotype from them, as shown by Sir W. R. Grove and others. These reproductions are admirable in every way, and furnish a proof that the daguerrean image is a relief.

**Fox Talbot Process.**—In January 1839 Fox Talbot described the first of his processes, photogenic drawing, in a paper to the Royal Society. He states that he began experimenting in 1834, and that in the solar microscope he obtained an outline of the object to be depicted in full sunshine in half a second. He published in the *Philosophical Magazine* full details of his method, which consisted essentially in soaking paper in common salt, brushing one side only of with about a 12% solution of silver nitrate in water, and drying at the fire. Fox Talbot stated that by repeating the alternate washes of the silver and salt—always ending, however, with the former—greater sensitiveness was attained. This is the same in every respect as the method practised by Wedgwood in 1802; but, when we come to the next process, which he called "calotype" or "beautiful picture," we have a distinct advance. This process Talbot protected by a patent in 1841. It may be briefly described as the application of silver iodide to a paper support. Carefully selected paper was brushed over with a solution of silver nitrate (100 grains to the ounce of distilled water), and dried by the fire. It was then dipped into a solution of potassium bromide containing about 10 grains to the ounce of water, and then allowed to dry. The plate was then fixed by brushing gallo-nitrate of silver over the surface of the plate. A sample of gallo-nitrate of silver, which has been described by Fizeau, is merely a mixture, consisting of 100 grains of silver nitrate dissolved in 2 oz. of water, to which is added one-sixth of its volume of acetic acid, and immediately before applying to the paper an equal bulk of hyposulphite of soda. The prepared paper is then ready for exposure in the camera, and, after a short insolation, develops itself in the dark, or the development may be hastened by a fresh application of the gallo-nitrate of silver. The picture is then fixed by washing it in clean water and drying slightly in blotting paper, after which it is treated with a solution of potassium bromide, and again washed and dried.
in 1850, on the introduction of collodion (q.v.), a very convenient vehicle on account of the facility with which the plates are prepared, and also because it is a substance as a rule totally unaffected by silver nitrate, which is not the case with other organic substances. This albumen forms a definite silver compound, as do gelatin, starch and gum. The employment of collodion was first suggested by Le Gray, but it remained for Frederick Scott Archer of London, closely followed by P. W. Fry, to make a really practical use of the discovery. When collodion is poured on a glass plate it leaves on drying a hard transparent film which under the microscope is slightly reticulated. Before drying, the film is gelatinous and perfectly adapted for holding in situ salts soluble in ether and alcohol. Where such salts are present they crystallize out when the film is dried, hence such a film is only suitable where the plates are ready to be immersed in the silver bath. As a rule, about five grains of the soluble gum-cotton are dissolved in an ounce of a mixture of equal parts of ether and alcohol, both of which must be of low specific gravity, .725 and .805 respectively. If the alcohol or ether be much diluted with water the gum-cotton (pyroxylin) precipitates, but, even if less diluted, it forms a film which is "crepey" and uneven. Such was the material which Le Gray proposed and which Archer brought into practical use. The opaque silver plate with its one impression was abandoned; and the paper support of Talbot, with its inequalities of grain and thickness, followed suit, though not immediately. When once a negative had been obtained with collodion on a glass plate—the image showing high lights by almost complete opacity and the shadows by transparency (as was the case, too, in the calotype process)—any number of impressions could be obtained by means of the silver-printing process introduced by Fox Talbot, and they were found to possess a delicacy and refinement of detail that certainly eclipsed the finest print obtained from a calotype negative. To any one who had practised the somewhat tedious calotype process, or the waxed-paper process of Le Gray with its still longer preparation and development, the advent of the collodion method must have been extremely welcome, since it effected a saving in time, money and uncertainty. The quality of photographic action was much increased, and the production of a different character of pictures thus became possible.

We give an outline of the procedure. A glass plate is carefully cleaned and pressed to the stream of trichloroethylene or spirits of wine (to which a little ammonia is often added), then wiped with a soft rag, and finally polished with a silk handkerchief or chamois leather. A collodion containing soluble iodides and bromides is made to fill the plate, which is left off to dry. A good standard formula for the collodion is 55 grains of pyroxylin, 5 oz. of alcohol, 5 oz. of ether; and in this liquid are dissolved 23 grains of ammonium iodide, 2 grains of cadmium iodide and 2 grains of cadmium bromide. When the collodion is set the plate is immersed in a bath of silver nitrate—a vertical form being that mostly used in England, whilst a horizontal dish is used on the Continent of Europe—a good formula for which is 350 grains of silver nitrate with 10 oz. of water. The plate is steadily lowered into this solution, and moved in it until all the requisite action has been performed. Aqueous solution of the silver and the solvents of the collodion is removed, when it is allowed to rest for a couple of minutes, after which period it is taken out and placed in the dark slide ready for exposure. After exposure, the papered plate is washed, the plate is withdrawn, and in a room lighted with yellow light the developing solution is applied, which originally was a solution of pyrogallic acid in water restrained in its action by the addition of acetic acid. One P. H. Delamotte was 9 grains by P. H. Delamotte, 2 grains of pyrogallic acid, 2 drachms of glacial acetic acid and 3 oz. of water. The image gradually appears after the application of this solution, building itself up from the silver nitrate clinging to the film, which is not dissolved by the distillation of the water. As the density be insufficient a few drops of silver nitrate are added to the pyrogallic acid solution and the developing action continued.

In 1854 Robert Hunt introduced another reducing agent, which is about 10 times better than ferrous sulphate. By increasing the necessary exposure of the plate is reduced and the image develops with great rapidity. A sample of this developing solution is 20 grains of ferrous sulphate, 20 minims of acetic acid, with 1 oz. of walpha. This solution often leaves the image thinner than is requisite for the formation of a good print, and it is intensified with pyrogallic acid and silver. Other intensifiers are used to increase the deposit on a plate by means of mercury or uranium, followed by other solutions to further darken the double salts formed on the film.

Such intensifying agents have to be applied to the image after the plate is fixed, which is done by a concentrated solution of hypochlorite of soda or by potassium cyanide, the latter salt having been first introduced by Martin and Marc Antoine Augustin Gaudin in 1846 (Le Mag. de la Photographie, April 23, 1846). To the fine grains of potatoes of cyanide to one ounce of water is the strength of the solution usually employed. The reaction of both these fixing agents is to form with the sensitive salts of silver double hypo-sulphites or cyanides, which are washed out with water and alcohol. The collodion process seems to have been recognized in its earliest days, Scott Archer (1852) and R. J. Bingham (1850) both mentioning it. We notice this, since as late as 1866 a patent-right in its use was sought to be enforced in America, the patent being taken out by James Curtin in July 1854.

Positive Pictures by the Collodion Process.—In the infancy of the collodion process it was shown by Horne that a negative image could be made to assume the appearance of a positive by whitening the metallic silver deposit. This he effected by using with the pyrogallic acid developer a small quantity of hydrochloric acid. A better result was obtained by P. W. Fry with ferrous sulphate and ferrous nitrate, whilst Hugh Diamond gave effect to the matter in a practical way. F. Scott Archer used mercuric chloride to whiten the image. To Robert Hunt, however, must be awarded the credit of noticing the action of this salt on the image (Phil. Trans., 1843). The whitened picture may be made to stand out against black velvet, or black varnish may be poured over the film to give the necessary black background, or, more recently, the positive pictures may be produced on japanned iron plates (ferrotype plates) or on japanned leather. This process is still occasionally practised by itinerant photographers.

Moist Collodion Process.—It is seen that for the successful working of the collodion process it was necessary that the plate should be exposed very shortly after its preparation; this was a drawback, inasmuch as it necessitated taking a heavy equipment into the field. In 1856, Sir William Crookes and J. Spiller published in the Philosophical Magazine a process whereby they were enabled to keep a film moist (so as to prevent crystallization of the silver nitrate) several days, enabling plates to be prepared at home, exposed in the field, and then developed in the dark room. The plate was prepared in the usual way and a solution of zinc nitrate and silver nitrate in water was made to flow over it. The hygroscopic nature of the zinc salt kept sufficient moisture on the plate to attain the desired end. Various modifications in procedure have been made.

Dry Plates.—It would appear that the first experiments with collodion dry plates were due to Marc Antoine Augustin Gaudin. In La Lumiere of the 22nd of April and the 27th of May 1854 he describes his researches on the question; whilst in England G. R. Muirhead, on the 4th of August 1854, stated that light acts almost as energetically on a dry surface as on a wet after all the silver has been washed away from the former previous to desiccation. J. M. Tauponot, however, seems to have been the first to use a dry-plate process that was really workable. His original plan was to coat a plate with collodion, sensitize it in the ordinary manner, wash it, cause a solution of albumen to flow over the surface, dry it, dip it in a bath of silver nitrate acidified with acetic acid, and wash and dry it again. The plate was then in a condition to be exposed, and was to be developed with pyrogallic acid and silver. In this method we have a double manipulation, which is long in execution, though perfectly effective.

A great advance was made in all dry-plate processes by the introduction of what is known as the "alkaline developer," which is, however, applicable to all plates on which silver nitrate is present in the free state. The developers previously described, either for collodion or paper processes, were dependent on the reduction of metallic silver by some such agent as ferrous sulphate, the reduction taking place gradually and the reduced particles aggregating on those portions of the film which had been acted upon by light. The action of light being to reduce the silver iodide, bromide or chloride, these reduced particles really acted as nuclei for the crystallized metal. It will be evident that in such a method of development the molecular attraction

An alkaline developer consists of an alkali, a reducing agent and a restraining agent. These bodies, when combined and applied to the solid silver bromide or chloride, after being acted upon by light, were able to reduce the sub-bromide or sub-chloride, and to build up an image upon it, leaving the unaltered bromine intact, except so far as it was used in the building up. In 1877, Sir W. Abney investigated this action. A dry plate was prepared by the bath process in the usual manner (to be described below), and exposed in the camera. The exposed film was coated with another film of collodio-bromide emulsion, which of course had not seen the light. An image was obtained from the double film by means of the alkaline developer, which penetrated through the upper unexposed film. The development was prolonged until an image appeared through the unexposed film, when the plate was fixed, washed and dried. A piece of gelatinous paper was cemented on the upper film, and a similar piece on the lower after both had been stripped off the glass. When quite dry the two papers were forcibly separated, a film adhering to each. The upper film, although never exposed to light, showed an image in some cases more intense than the under film. The action of the alkaline developer was here manifest: the silver bromide in close contiguity to the exposed particles was reduced to the metallic state. Hence, from this and similar experiments, Abney concluded that silver bromide could not exist in the presence of a freshly precipitated or reduced metallic silver, and that a sub-bromide was immediately formed. From this it will be seen that the deposited silver is well within the sphere of molecular attraction, and that consequently a less exposure (i.e. the reduction of fewer molecules of the sensitive salt) would give a developable image.

The alkalies used embraced the alkalies themselves and the mono-carbonates. The sole reducing agent up till recent times was pyrogallic acid. In the year 1880 Abney found that hydroquinone was even more effective than pyrogallic acid, its reducing power being stronger. Various other experimentalists tried other kindred substances, but without adding to the list of really useful agents until recently.

The following are some of the most effective:

Eikonogen Developer.

Solution B.

Sodium carbonate . . . . 100 parts.  
Sodium sulphite . . . . 125 "  
Potassium bromide . . . . 3 "  
Water . . . . 1000 "

A and B solutions are mixed together in equal proportions.

Besides these, there are several more, such as adour, glycin, pyrocatechin, which have been used with more or less success. They all give a black in lieu of that dark olive-green deposit of the metallic silver so often obtained with pyrogallic acid. All are alkaline developers, and the image is built up from the sensitive salt within the film. They are applicable to gelatin or collodion plates, but for the latter rather more bromide of an alkali is added, to retard fogging.

Another set of developers for dry plates dependent on the reduction of the silver bromide and the metallic state is founded on the fact that certain organic salts of iron can be utilized. In 1877 M. Carey Lea of Philadelphia and William Willis announced almost simultaneously that a solution of ferrous oxalate in neutral potassium oxalate was effective as a developer, and from that date its use has been acknowledged. In 1882 J. M. Eder demonstrated that gelatino-silvere chloride plates could be developed with ferrous citrate, which could not be so readily accomplished with ferrous oxalate. The exposure for chloride plates when developed by the latter was extremely prolonged.

In the same year Abney showed that if ferrous oxalate were dissolved in potassium citrate a much more powerful agent was formed, which allowed not only gelatino-chloride plates to be readily developed but also collodio-chloride plates. These plates were undevelopable except by the precipitation method until the advent of the agents last-mentioned owing to the fact that the chloride was as readily reduced as the sub-chloride.

Amongst the components of an alkaline developer we mentioned a restrainer. This factor, generally a bromide or chloride of an alkali, serves probably to form a compound with the silver salt which has not been acted upon by light, and which is less easily reduced than is the silver salt alone—the altered particles being left intact. The action of the restrainer is regarded by some as due to its combination with the alkali. But whichever theory is correct the fact remains that the restrainer does make the primitive salt less amenable to reduction. Such restrainers as the bromides of the alkali and through chemical means; but there are others which act through physical means, an example of which we have in the preparation of a gelatin plate. In this case the gelatin wraps up the particles of the silver compound in a colloidal sheath, as it were, and the developing solution only gets at them in a very gradual manner, for the natural tendency of all such reducing agents is to attack the particles on which least work has to be expended. In the case of silver sub-bromide the developer has only to remove one atom of bromine, whereas it has to remove two in the case of silver bromide. The sub-bromide formed by light and that subsequently produced in the act of development are therefore reduced. A large proportion of gelatin compared with the silver salt in a film enables an alkaline developer to be used without any chemical restrainer; but when the gelatin bears a small proportion to the silver such a restrainer has to be used. With collodion films the particles of bromide are more or less unenveloped, and hence in this case some kind of chemical restrainer is absolutely necessary. We may say that the organic iron developers require less restraining in their action than do the alkaline developers.

As Russell's process the plate was prepared by immersion in a strong solution of silver nitrate and then washed and a preservative applied. The last-named agent executes two functions; one being to absorb the halogen liberated by the action of light and the other to preserve the film from atmospheric action. Tannin, which Major Russell mentioned, if we mistake not, is a good absorbent of the halogens, and acts as a varnish to the film. Other collodion dry-plate processes carried out by means of the silver-nitrate bath were very numerous at one time, many different organic bodies being also employed. In most cases ordinary iodized collodion was made use of, a small percentage of soluble bromide being as a rule added to it. When plates were developed by the alkaline method this extra bromide induced density, since it was the silver bromide alone which was adsorbable to it, the iodide being almost entirely unaffected by the weak developer which was at that time in general use.
PHOTOGRAPHY

Dry-Plate Bath Process.—One of the most successful bath dry-plate processes was introduced by R. Manners Gordon. The plate was given an edging ofalbumen and then coated with ordinary iodized collodion to which one grain per ounce of cadmium bromide had been added. It was kept in the silver-nitrate bath for ten minutes, after which it was washed thoroughly. The following preservative was then applied:

1. Gum arabic
2. Sugar candy
3. Water
4. Gallic acid
5. Water

These ingredients were mixed just before use and, after filtering, applied for one minute to the plate, which was allowed to drain and set up to dry naturally. Great latitude is admissible in the exposure; it should rarely be less than four times or more than twenty times that which would be required for a wet plate under ordinary circumstances. The image may be developed with ferrous sulphate restrained by a solution of gelatin and glacial acetic acid, to which a solution of silver nitrate is added just before application, or by an alkali developer.

In photographic processes not only has the chemical condition of the film to be taken into account but also the optical. When light falls on a semi-opaque or translucent film it is scattered by the particles or molecules which passes through the glass plate to the eye. The amount of light absorbed is very small, and the rays are partly transmitted and partly reflected, a very small quantity of them being absorbed by the material of the glass. Theory points out that the strongest reflection from the back of the glass should take place at the "critical" angle. In 1854, Abney investigated the subject and proved that practice agreed with theory in every respect, and that the image of a point of light in development on a plate was surrounded by a ring of reded silver caused by the reflection of the scattered light from the back surface of the glass, and that this ring was shaded inwards and outwards in such a manner that the shading varied with the intensity of light, reflected at different angles. To avoid "halation," as this phenomenon is called, it was usual to cover the back of dry plates with some material which would not pass in optical contact with it, and as nearly as possible of the same density as glass, and which at the same time should absorb all the photographically active rays. This was called "backing a plate."

Collodion Emulsion Processes.—In 1864 W. B. Bolton and B. J. Sayce published the germ of a process which revolutionized photographic manipulations. In the ordinary colloid process a sensitive film is procured by coating a glass plate with collodion containing the iodide and bromide of some soluble salt, and then, when set, immersing it in a solution of silver nitrate in order to form silver iodide and bromide in the film. The question that presented itself to Bolton and Sayce was whether it might not be possible to get the sensitive salts of silver formed in the collodion whilst liquid, and a sensitive film given to a plate by merely letting this collodion, containing the salts in suspension, flow over the glass plate. Gaudin had attempted to do this with silver chloride, and later G. W. Simpson had succeeded in perfecting a printing process with collodion containing silver chloride, citric acid and silver nitrate; but the chloride until recently has been considered a slow working salt, and nearly incapable of development. Up to the time of W. B. Bolton and B. J. Sayce's experiments silver iodide had been considered the staple of a sensitive film on which to take negatives; and though bromide had been used by Major Russell and others, it had not met with so much favour as to lead to the omission of the iodide. At the date mentioned the suspension of silver iodide in collodion was not thought practicable, and the inventors of the process turned their attention to silver bromide, which they found could be secured in such a fine state of division that it remained suspended for a considerable time in collodion, and even when precipitated could be redispersed by shaking the suspension. The outline of the method was to dissolve soluble bromide in plant collodion, and add to it drop by drop an alcoholic solution of silver nitrate, the latter being in excess or defect according to the will of the operator. To prepare a sensitive surface the collodion containing the emulsified sensitive salt was poured over a glass plate, allowed to set, and washed till all the soluble salts resulting from the double decomposition of the soluble bromide and the silver nitrate, together with the unaltered soluble bromide or silver nitrate, were removed, when the film was exposed wet, or allowed to dry and then exposed. The rapidity of these plates was not in any way remarkable, but the process had the great advantage of doing away with the sensitizing nitrate of silver bath, and thus avoiding a tiresome operation. The emulsions developed by the alkali method, and gave images, which if not primarily dense enough, could be intensified by the application of pyrogallic acid and silver nitrate as in the wet collodion process. Such was the crude germ of a method which was destined to effect a complete change in the aspect of photographic negative taking; but for some time it lay dormant. In fact there was at first much to discourage trial of it, since the plates often became veiled on development.

M. Carey Lea of Philadelphia, and W. Cooper, jun., of Reading, may be said to have given the real impetus to the method. Carey Lea, by introducing an acid into the emulsion, established a practicable colloid emulsion process, which was rapid and at the same time gave negative pictures free from veil. To secure the rapidity Carey Lea employed a fair excess of silver nitrate, and Colonel H. Stuart Wortley gained further rapidity by a still greater increase of it; the trial use of acid as the only means by which this could be effected without hopelessly spoiling the emulsion. The addition of the mineral acids such as Carey Lea employed is to prevent the formation of (or to destroy when formed) any silver sub-bromide by which the development can take place. Abney first showed the theoretical effect of acids on the sub-bromide, as also the effect of oxidizing agents on both the above compounds (see below). A more valuable modification was at last arrived at by W. B. Bolton, who first showed that a person of the process, who allowed the ether and the alcohol of the collodion to evaporate and then washed away all the soluble salts from the gelatinous mass formed of pyroxylin and sensitive salt. After washing for a considerable time, the pellicle was dried naturally or washed with water alcohol and then the pyroxylin removed either by ethereal and alcohol, leaving an emulsion of silver bromide, silver chloride or silver iodide, or mixtures of all suspended in colloid. In this state the plate could be coated and dried at once for exposure. The results to this fact greatly improved, but the use of a considerable number of dry plates with the bath, in order to prevent the atmosphere from rendering the surface of the film spotty or insensitive on development. This modification had the great advantage of allowing a large quantity of sensitive salt to be prepared to precisely the same value as to rapidity of action and quality of film.

A great advance in the use of the collodion bromide process was made by Colonel Stuart Wortley, who in June 1873 made known the action of a strongly alkaline developer, by which the weak one which up to that time had usually been employed for a colloid emulsion plate, or indeed any dry plate.

An example of the preparation of a colloid emulsion and the developmental process is as follows:—

1. Pyrogallic acid
2. Alcohol
3. Potassium bromide
4. Water distilled
5. Ammonium carbonate
6. Water

To develop the plate 6 minims of No. 1, § drachm of No. 2, and 3 drachms of No. 3 are mixed together and made to flow over the plate after washing the preservative off under the tap. Sometimes the

1 An account of Sayce's process is to be found in the Photographic News of October 1865, or the Photographic Journal of the same date.  
2 The advantages of this salt were pointed out by Leon Warner in 1875.
PHOTOGRAPHY

Technique developed is conducted in a flat dish, sometimes the solution is poured on the plate. The unredused salts are eliminated by either cyanide of potassium or sodium hyposulphite. Intensity may be given to the image, if requisite, either before or after the fixing operation. A saturated solution of potassium bromide is applied to the emulsion, the developer is made in one of two ways — (1) by saturating a saturated solution of neutral potassium oxalate with ferrous oxalate, and adding an equal volume of a solution (to grains to 1 oz. of water) of potassium bromide to restrain the action, or (2) by mixing according to Eders plan, 3 volumes by measure of a saturated solution of the potassium oxalate with 1 volume by measure of a saturated solution of ferrous sulphate, and adding to the ferrous oxalate solution an equal bulk of the above sodium hyposulphite solution. The development is conducted in precisely the same manner as indicated above, and the image is fixed by one of the same agents.

Gelatin Emulsion Process. — The facility with which silver bromide emulsion could be prepared in collodion had turned investigation into substitutes for it. As early as September 1873 Dr. R. L. Maddox had tried emulsifying the silver salt in gelatin, and had produced negatives of rare excellence. In November 1873 J. King described a similar process, getting rid of the soluble salts by washing. Efforts had also been made in this direction by J. Burgess in July 1874. R. Kennett in 1874 may be said to have been the first to put forward the gelatin emulsion process in a practical and workable form, as he then published a formula which gave good and quick results. It was not till 1878, however, that the great capabilities of silver bromide when held in suspension by gelatin were fairly known; in March of that year C. Bennett showed that by keeping the gelatin solution liquid at a low temperature for as long as seven days extraordinary rapidity was conferred on the sensitive salt. The molecular condition of the silver bromide seemed to be altered, and to be amenable to a far more powerful developer than had hitherto been dreamt of. In 1874 J. S. Stas had shown that various modifications of silver bromide and chloride were possible, and it seemed that the green molecular condition (one of those noted by Stas) of the bromide was attained by prolonged warming. It may be said that the advent of rapid plates was 1878, and that the full credit of this discovery should be allotted to C. Bennett. Both Kennett and Bennett got rid of the soluble salts from the emulsion by washing; and in order to attain success it was requisite that the bromide should be in excess of that necessary to combine with the silver nitrate used to form the emulsion.

In June 1879 Abney showed that a good emulsion might be formed by precipitating a silver bromide by dropping a solution of a soluble bromide into a low solution of silver nitrate. The supernatant liquid was decanted, and after two or three washings with water the precipitate was mixed with the proper amount of gelatin. D. B. van Monckhoven of Ghent, in experimenting with this process, hit upon the plan of obtaining the emulsion by acting on silver carbonate with hydrobromic acid, which left no soluble salts to be extracted. He further, in August 1879, announced that he had obtained great rapidity by adding to the bromide emulsion a certain quantity of ammonia. This addition rapidly altered the silver bromide from its ordinary state to the green molecular condition referred to above. At this point we have the branching off of the gelatin emulsion process into two great divisions, viz. that in which rapidity was gained by long-continued heating, and the other in which it was gained by the use of ammonia—a subdivision which is maintained to the present day.

Opinions as to the merits of the two methods are much divided, some maintaining that the equality of the heated emulsion is better than that produced by alkali, and vice versa. We may mention that in 1885 Dr. A. Herschel introduced a process of using alcohol in which the idea of inducing rapid drying of the plates, and in the same year H. W. Vogel of Berlin introduced a method of combining gelatin and pyroxylin together by means of a solvent which acted on the gelatin and allowed the addition of alcohol in order to dissolve the pyroxylin. This “colloido-gelatin emulsion” was only a modified process, which is not surprising, since its preparation involved the inhalation of the fumes of acetic acid.

1 For further details the reader is referred to Instruction in Photography, 11th ed., p. 362.

The warming process introduced by Bennett was soon superseded. Colonel Stuart Worrley in 1879 announced that, by raising the temperature of the vessel in which the emulsion was stirred to 150° F., instead of days being required to give the desired sensitivity only a few hours were necessary. A further advance was made by boiling the emulsion, first practised, we believe, by G. Mansfield in 1879. Another improvement was effected by W. B. Bolton by emulsifying the silver salt in a small quantity of gelatin and then raising the emulsion to boiling point, boiling it for from half an hour to an hour, when extreme rapidity was attained. Many minor improvements in this process have been made from time to time. It may be useful to give an idea of the relative rapidities of the various processes we have described.

TECHNIQUE OF PHOTOGRAPHY

Gelatin Emulsions.

The following is an outline of two representative processes. All operations should be conducted in light which can act but very slightly on the emulsion, and it is more necessary with this process than with others on account of the extreme case which is obtained when equal to the solutions are added. In this case the emulsion is upset in giving rise to the molecule which is developable. The light to work with is gaslight or candlelight passing through a sheet of Chance’s stained red glass backed by orange paper. Stained red glass allows but few chemically effective rays to pass through it, whilst the orange paper diffuses the light. If daylight is employed, it is as well to have a double thickness of orange paper. The following should be weighed out:

1. Potassium iodide 5 grs.
2. Potassium bromide 135
3. Nelson’s No. 1 photographic gelatin 100
4. Silver nitrate 175
5. Autotype or other hard gelatin 100
6. Nelson’s No. 1 gelatin 100

Nos. 3 and 4 are rapidly covered with water or washed for a few seconds under the tap to get rid of any dust. No. 2 is dissolved in boiling water, and the gelatin emulsion till it assumes a light cherry colour. No. 1 is dissolved in 60 minims of water, No. 4 is dissolved in | oz. of water, and No. 3 is allowed to swell up in | oz. of water, and is then dissolved by heat. All the fluids are mixed in a tub. The solutions are placed in water at 150° F. and carried to the “dark room,” as the orange-lighted chamber is ordinarily called; Nos. 3 and 4 are then mixed together in a jar or flask, and No. 2 added drop by drop till half its bulk is gone, when No. 1 is added to the two and the double solution is put in a warm place and left to stand. When all is added there ought to be formed an emulsion which is very tricky but examined by gaslight, or by the light of the flask containing the emulsion is next placed in boiling water which is kept in a state of ebullition for about three-quarters of an hour. It is then ready, when the contents of the flask have cooled down to about 100° F. for the addition of No. 5, which should be placed in 2 oz. of water to swell and be dissolved. This is then added drop by drop to the emulsion, and the double solution is put in a cool place to set, after which it is turned into a piece of coarse canvas or mosquito netting made into a bag. By squeezing, threads of gelatin containing the sensitive salt can be obtained. After all the liquid has been drawn off and the emulsion threads are extracted. This is readily done in two or three hours by frequently changing the water, or by allowing running water to flow over the emulsion-threads. The gelatin is then drained by straining canvas over a jar and turning out the threads on to it, after which it is placed in a flask, and warmed till it dissolves, half an ounce of alcohol being added. Finally it is filtered through chamois leather or swansdown calico. In this state it is ready for the plates.
to the gelatin the remainder of No. 5 is added before the addition of the alcohol, and before filtering.

Developing the Plates.—Glass plates are best cleaned with nitric acid, rinsed in the potash solution, rinsed again, and dried with a clean cloth. They are then ready for the emulsion, which, after being warmed to about 120° F., is poured on a sheet to cover the whole surface. This being done, the plates are placed in the developing cauldron, and are allowed to stay there till the gelatin is thoroughly softened; they are then put in for five or six hours, which a current of warm air is made to pass. It should be remarked that the warmth is only necessary to enable the air to take up the moisture from the gelatin. They ought to dry in about twelve hours, and they are ready for use.

Exposure.—With a good emulsion and on a bright day the exposure of a plate to a landscape, with a lens whose aperture is one-fifth, and drying in a current of air, should not be more than one-half to one-fifth of a second. This depends, of course, on the nature of the view; if there be foliage in the immediate foreground, it will be longer. In the portrait-studio, under the same circumstances, a plate with a portrait lens may be held from half a second to four or five seconds.

Development of the Plate.—To develop the image either a ferrous oxalate solution or alkaline pyrogallic acid may be used. No chemical restrainer such as potassium bromide is necessary, since the gelatin itself acts as a natural restrainer. If the alkaline developer be used, the following may be taken as a good standard:

<table>

One dram of each of these is taken and the mixture made up to 2 oz. with water. The plate is placed in a dish and the above poured over it without stoppage, whereupon the image gradually appears and, if the exposure has been properly timed, gains sufficient density for printing purposes. It is fixed in a solution of hypoosmulate of soda, as in the other processes already described, and then thoroughly washed for two or three hours to eliminate all the sensifying agent. This long washing is necessary on account of the nature of the gelatin. It is essential.

Intensifying the Negative.—Sometimes it is necessary to intensify the negative, which can be done in a variety of ways with mercury salts. An excellent plan, introduced by Chapman Jones, is to use a saturated solution of mercuric chloride. It is fixed in a solution of hypoosmulate of soda, and after thorough washing the negative is treated with ferrous oxalate. This latter can be repeated till sufficient density is attained. With most methods with mercury the image is apt to become yellow and to fade; with this apparently simple method the result of the gelatin is also improved.

Varnishing the Negative.—The negative is often protected by receiving first a film of plain collodion and then a coat of shellac or other photographic varnish. This protects the gelatin from moisture and scratches. The albumen is then replaced with the silver nitrate, owing to contact with the sensitive gelatin it has been reduced in silver printing. Another varnish is a solution of celluloid in amyl acetate. This is an excellent protection against damp.

Printing Processes.

The first printing process may be said to be that of Fox Talbot (see above), which has continued to be generally employed (with the addition of albumen to give a surface to the print—an addition first made, we believe, by Fox Talbot).

Paper for printing is prepared by mixing 150 parts of amomium chloride with 240 parts of spirits of wine and 2000 parts of water, though the proportions may vary. These ingredients are dissolved, and the whites of fifteen fairly-sized eggs are added and the whole beaten to a froth. This is advisable to add a drop of carbolic acid to prevent decomposition. The albumen is then added, after two or three days to settle, when it is filtered through a sponge placed in a funnel, or through two or three thicknesses of fine muslin, and the mixture is then strained. The paper is cut of convenient size and allowed to float on the solution for also another (described) day, when it is taken off and dried in a warm room. For dead prints, or prints which is to take place, plain salted paper is useful. It can be made by the following proportions—90 parts of amomium chloride, 100 parts of soda citrat, 20 parts of gelatin, 50 parts of distilled water. The gelatin is first dissolved in hot water and the remaining components are added. It is next filtered, and the paper allowed to float on it for three minutes, then withdrawn and dried.

Sensitizing Bath.—To sensitize the paper it is floated on a 10% solution of silver nitrate for three minutes. It is then hung up and allowed to dry, after which it is ready for use. To print the image the paper is placed in a printing frame over a negative and exposed to light. It is allowed to print till such time as the image appears rather darker than it should finally appear.

Toning and Fixing the Print.—The next operation is to tone and fix the print. In the thiocyanate method this was accomplished by means of a bath of sel d’or—a mixture of hypochlorite of silver and silver chloride. This gilded the darkened parts of the print which light had reduced to the semi-metallic state: and on the removal of the tone, the print is rendered dome as silver. The third method is to use an image composed of metallic silver, an organic salt of silver and an electrolyte. There was a suspicion, however, that part of the coloration was due to a combination of sulphur with the silver, not that pure silver sulphide that appears to be a by-product of silver chloride, but the sulphated organic salt of silver seems to be liable to change. The new method of the use of an alkaline toner, or rather, we should say, of neutral toning, by employing gold chloride with a salt, such as the carbonate or sulphate of some chelating agent, such as oxalate, at a certain time, but the sulphated organic salt of silver is every day disappearing, a new, and stronger acid comes into play, such as nitric acid, which must exist in the paper after printing. This branch of photography owes much to the Rev. T. F. Hardwich, he having used methods which result in extensive and useful researches in connection with it during 1854 and subsequent years. A. Chapman and A. Girard, a little later, also investigated the matter with fruitful results.

The following may be taken as two typical toning-baths:

| Gold chloride | 1 part. |
| Sodium carbonate | 5 parts. |
| Water | 500 oz. |
| Borax | 100 oz. |
| Water | 4000 oz. |
| Gold chloride | 1 part. |
| Water | 4000 oz. |

These are mixed together, the water being warmed. When cool the solution is ready for use. In toning the print there is a distinct difference in the modus operandi according to the toning-bath employed. Thus in the first two baths the print is thoroughly washed, and then placed in weak acid, then free from gold chloride, that salt forming no part in the chemical reactions. On the other hand the free chlorine is used, the presence of free silver nitrate or some active chlorine absorber is a necessity. In 1872 Abney showed that with such a free silver nitrate might be eliminated, and if the print were immersed in a solution of a salt such as lead nitrate the toning action proceeded rapidly, and without causing any fading of the image whilst toning, which was the case when the free silver nitrate was totally removed and no other chlorine absorber substituted. There was an important factor, and one which had been overlooked. In the third bath the free silver nitrate should only be partially removed by washing. The print, having been partially removed or thoroughly washed, as the case may be, is immersed in the following solution of gold chloride for a purple or bluish tone, after which it is ready for fixing. The solution used for this purpose is a 20% solution of hypochlorite of soda, to which it is bated with two drops of ammonia in order to render it alkaline. About ten minutes suffice to effect the conversion of the chloride into hypochlorite of silver, which is soluble in hypochlorite of soda and can be removed by washing. The ammonia salts of silver, however, to form a different salt, which is partially insoluble, but which the ammonium helps to remove. If it is not removed there is a sulphur compound left behind, according to J. Spiller, which by time and exposure becomes yellow. There is another difficulty relative to fixing prints to be avoided, as this reagent attacks the organic compound of ammonia and would render the print a ghost. The washing of silver prints should be very complete, since it is said that the least trace of hypochlorite left behind renders the print the image a mere matter of time. The stability of a print has been still more increased by immersing it, after washing, in a solution of alum. The alum, like any acid body, decomposes the hypochlorite into sulphur and sulphuric acid. In the case of a print, it seems probable that the destruction of the hypochlorite by time is not the occasion of its failure, but that its hygroscopic character is. This, however, is a moot point. It is usual to wash the prints some hours in running water, or to use half a dozen changes of water, and between successive changes the print is placed in a light box. This, however, is not the occasion of the back of each print separately, are equally or more efficacious. On drying the print assumes a darker tone than it has after leaving the fixing bath.

Different tones can thus be given to a print by different toning-baths; and the gold itself may be deposited in a reddish or in a blue form. The former molecular condition gives the red and sepia tones, and the latter the blue and black tones. The degree of minute subdivision of the gold may be conceived when it is
stated that, on a couple of sheets of albuminized paper fully printed, the gold necessary to give a decided tone does not exceed half a grain.

Colloidal Chloride Silver Printing Process.—In the history of the emulsion processes we stated that Goldschmidt attempted to obtain a silver chloride suspended in colloid, but it was not till the year 1864 that any practical use was made of the suggestion so far as printing is concerned. In the autumn of that year George Wharton Simpson worked out a method which has been most successfully employed. The formula appended is Simpson's—

1. Silver nitrate 60 parts.
2. Distilled water 60.
3. Silver nitrate 1000.
4. Alcohol 64.

To every 1000 parts of plain colloidon 30 parts of No. 1, previously mixed with 60 parts of alcohol, are added, 60 parts of No. 2 are next mixed with the colloidon, and finally 30 parts of No. 3. This is emulsified in nitric acid and silver nitrate. The defect of this emulsion is that it contains a large proportion of soluble salts, which are apt to crystallize out on drying, more particularly if it be applied to glass plates. The addition of the citric acid and the excess of silver nitrate is the key to the whole process; for, unless some body were present which on exposure to light was capable of forming a highly-coloured organic oxide of silver, no vigour would be obtained in printing. It proved that the addition of a very small amount of citric acid or silver chloride of lime or by ammonium sulphocyanide and gold, which is practically a return to the sol d'or bath. The organic salt formed in this process does not seem so prone to be decomposed by keeping as do the silicium emulsions, and the washing is more completely carried out. There are in the market several papers which are colloidal-chloride.

Gelatino-citro-chloride Emulsion.—A modified emulsion printing process was patented by Anney in 1881, which consisted in suspending silver chloride and silver citrate in gelatin, there being no excess of silver present. The formula of producing it is as follows:

<table>
<thead>

</tbody>
</table>

Nos. 2 and 3 are mixed together whilst warm, and No. 1 is then gently added, the gelatin solution being kept in brisk agitation. This emulsion is then applied to the paper, and the gelatin containing the suspended salts is heated for five minutes at boiling point, when it is allowed to cool and subsequently slightly washed, as in the gelatino-bromide emulsion. It is then ready for applying to the paper, and all prints are of a beautiful colour, and seem to be fairly permanent. They may be readily toned by the borax or by the chloride of lime toning-bath, and are fixed by the hyposulphite solution of the strength before given. Most, if not all, the gelatin papers now extant are made somewhat after this manner.

Printed with Salts of Uranium.—The sensitiveness of the salts of uranium to light seems to have first been discovered by Niepce, and was subsequently applied to photography by J. J. Berthelot in France and G. H. Lowes in England. One of the original formulations consisted of 20 parts of uranous nitrate with 600 parts of water. Paper, which is better if slightly sized previously with gelatin, is floated on this solution. When dried, it is sufficiently in a negative, and a fine image is produced; but it can be developed into a strong one by 6 to 10% solution of silver nitrate to which a trace of acetic acid has been added, or by a 2% solution of gold chloride. In both these cases the silver nitrate is deposited in the metal, and in some cases potassium ferrocyanide. Another developer is a 2% solution of potassium ferrocyanide to which a trace of nitric acid has been added, sufficient to give a red colouration. The development takes place most readily by letting the paper float on the surface of a weak hyposulphite of soda.

Printed with Chromates: Carbon Prints.—The first mention of the use of potassium bichromate for printing purposes seems to have been made by Munro Ponton in May 1859, when he stated that paper, if saturated with this salt and dried, and then exposed to the sun's rays through a drawing, would produce a yellow picture on a ground of nothing more being required to fix it than washing it in water, when a white picture on an orange ground was obtained. In 1840 Edmond Becquerel announced that paper sized with iodide of starch and soaked in potassium bichromate was, on drying, more sensitive than unsized paper. Joseph Dixon of London, in 1841, described a method of printing with notes which were transferred to a sensitized paper by using gum arabic with potassium bichromate spread upon a lithographic stone, and, after exposure of the sensitive surface through a bank-note, by washing away the unaltered gum and fixing the picture. The method may be improved on with slight modifications, has been used by Simonau and Toovey of Brussels, and produces excellent results. Dixon's method, however, was published in the *Scientific American* in 1854, and consequently the method was registered as a patent. The photography process (see below), published in 1852. On 1st of December 1855 Alphonse Poitevin took out a patent in England, in which he vaguely described a method of taking a direct carbon-copy, 'rendering gelatin insensitive through the action of light on potassium bichromate.' There is no doubt that John Bowden of Dorchester, who perhaps was the first to produce veritable carbon-prints, notwithstanding that Trestud de Beauregard took out a somewhat similar patent to Poitevin's at the end of 1857. Pouncey, published his process on the 1st of January 1861, but, as described by him, it was the only one in a perfect state, half-tones being wanting. The cause of this was first pointed out by Abbe Laborde in 1860, while describing a kindred process in a letter to J. P. Pouncey. With the addition of a sensi-tive film, however thin it may be, distinct surfaces must be recognized— an outer, and an inner which is in contact with the paper. The action of light commences on the outer surface; in the inner, it has to overcome the action of the silver, and are washed away." J. C. Burnett in 1858 was the first to endeavour to get rid of this defect in carbon printing. In a paper to the Photographic Society of London he says, "There are two essential requirements in a carbon-print (2) to render its patentable. Firstly, it must be a preparation and not prepared side (and not its prepared side, as in ordinary printing) placed in contact with the negative in the pressure-frame, as it is only by printing in this way that we can expect to be able afterwards to remove the carbon part of the mixture. In a positive of this sort printed from the front or prepared side the adherence of half-tones by washing away more or less depth of the mixture, according to the depth to which it has been fixed. In this respect, in practice when the positive is printed, the surface and in consequence protecting the soluble part from the action of the water used in washing; so that neither is removed, or by steeping very long till the inner soluble part is dissolved away, the surface is left with a well-defined image without losing the paper white." This method of exposing through the back of the paper was crude and unsatisfactory, and in 1860 Faris urged a process in which, after exposure to light of the gelatin film which contained pigment, the surface was coated with collodion, and the print placed in warm water, where it separated from the paper support and could be transferred to glass. Poitevin successfully opposed this patent, for he had used this means of detaching the carbon in his original patent of 1854. Other methods of carbon and of bichromate were used. J. C. Burnett gave an impetus to carbon-printing, and J. W. Swan took up the matter, and in 1864 secured a patent. One of the great features in Swan's innovations was that he produced a carbon process by coating paper with a mixture of gelatin, sugar and colouring matter, and rendered sensitive to light by means of potassium or ammonium bichromate. After exposure to light the paper is washed, and after being on the surface to which it was made to be by pressure. The print was inserted in hot water, the paper backing stripped off, and the soluble gelatin containing colouring matter washed away. The picture could be transferred to its final support of paper. In 1864 John Johnson of London took out a patent in which he claimed that carbon-tissue which had been soaked in water for a short period, due to its tendency to swell further, would adhere to any waterproof surface, and could be transferred to another paper, or the paper material being applied. This was a most important improvement. Johnson also applied soap to the gelatin to prevent its excessive brittleness on drying, and made its final support of gelatinized paper or parchment, where a larger area of paper was required. He patented a flexible support for developing on; this was a sized paper coated with gelatin and treated with an ammoniacal solution of shellac in borax, on which wax or resin was rubbed. The advantage of this method was that the carbon picture could have no tendency to contract from the lighter parts, which they were apt to do when a metal plate was used, was as the case in Johnson's original process. With this patent, and minor improvements made since, carbon-printing has arrived at its present state of perfection.

According to P. E. Liesegang, the carbon-tissue when prepared on a large scale consists of from 120 to 150 grains of gelatin (a soft kind), 15 grains of soap, 21 grains of sugar and from 4 to 8 grains of dry colouring matter. The last-named may be of various kinds, from lamp-black pigment to soluble colours such as azulinar. The gelatin, sugar and soap are put in water and allowed to stand for an hour, and then melted, the liquid afterwards receiving the
colours, which have been ground on a slab. The mixture is filtered through fine muslin. In making the tissue in large quantities the two ends of a piece of roll-paper are pasted together and the paper hung on two rollers; one of wood about 5 in. in diameter is fixed near the top, and the other, which is crooked and grooveless, accommodates the gelatin solution, the paper being brought into contact with the surface of the gelatin by being made to revolve on the rollers. The thickness of the coating is proportional to the rate at which the paper revolves, and the thickness of the coating varies according to the strength of the coating. The paper is taken off the rollers, cut through, and hung up to dry on wooden laths. If it be required to make the tissue sensitive at once, 120 grains of potassium bichromate should be added; but the sensitivity is increased by allowing the coating to dry more slowly. The carbon-tissue when prepared should be floated on a sensitising bath consisting of one part of potassium bichromate in 40 parts of water. This is effected by turning up about 1 in. from the end of the coat, and then loosening it from its fixing, and letting it unroll along the surface of the sensitising solution, where it is allowed to remain till the gelatin film feels soft. It is then taken off and hung up to dry in a dark room through which a current of dry warm air is passing. Tissue dried quickly, though not so sensitive, is more manageable to work on than the more slowly dried. As the tissue is coloured, it is not possible to ascertain by inspection whether the printing operation is sufficiently carried out, and in order to ascertain this it is usual to place a piece of ordinary silvered paper in an actinometer, or photometer, alongside the carbon-tissue to ascertain the amount of light that has acted on it. There are several devices for ascertaining this amount, the simplest is to compare the silvered paper used with an impregnated screen of gold-beater's skin. The value of 1, 2, 3, &c., thicknesses of the skin as a screen to the light is ascertained by experiment. Supposing it is judged that a sheet of tissue under some one negative is not satisfactory, it may be renewed. A coated sheet of tissue, being more flexible than solubles, chlorid of silver paper is placed alongside the negative beneath the actinometer and allowed to remain there until it takes a visible tint beneath a number of thicknesses equivalent to the strength of the negative. A further sheet of tissue being put on top, and the printing frame—supposing a double transfer to be made—is placed in a dish of cold water, face downwards, along with a piece of Sawyer's flexible support. When the edges of the tissue begin to curl inwards, it is removed from the actinometer, dampened, and placed together and placed flat. The water is pressed out with an Indian rubber squezer or "squeegee" and the two surfaces adhere. About a couple of minutes later they are placed in warm water of about 90° C. The silvered paper will have taken up the light which has been absorbed by the gelatine, and the solubles will now have dried. The solution next it becoming soluble, can be stripped off, leaving the image (reversed as regards right and left) on the flexible support. An application of warm water removes the rest of the soluble gelatin and pigments. When dried the image is transferred to its permanent support. This usually consists of white paper coated with gelatin and made insoluble with chrome alum, though it may be mixed with barium sulphate or other similar pigments. This treatment exposes the paper to the action of light; when this has been done it is to be washed in cold water till it becomes slimy to the touch; and the surface of the dampened print is brought into contact with the surface of the transfer-paper, in the same manner as was done with the flexible support. The image on the print is transferred to the impression on the paper, and the gelatin image can be stripped off the flexible support, which may be used again as a temporary support for other pictures. If a reversed negative is used the image may be transferred at once to the permanent support instead of to the flexible support, which is a point of practical value, since single-transfer are better than double-transfer prints.

*Printing with Salts of Iron.*—Sir John Herschel and Robert Hunt entered into various methods of printing with salts of iron. At the present time or two or three are practised, being used in draftsmen's offices for copying tracings (see SUN-COPYING).

**Photo-mechanical Printing Processes.**—Poiutein claimed to have discovered in 1854 that a sheet of gelatin impregnated with potassium bichromate, after being acted upon by light and aqua ammonia, would receive greasy ink on those parts which had been affected by light. But Paul Reitho of London seems to have made the discovery previous to 1854, when it was stated by him that the gelatin was inked with printing ink before being transferred to stone or zinc. L. M. Tessier de Motay (1856) and C. M. Reede of Metz, however, seem to have been the first to produce half-tones from gelatins by the use of metallic plates. The process provided metallic plates with gelatin impregnated with potassium or ammonium bichromate or tri-chromate and mercuric chloride, then treating with silver solute, exposing to light through a negative, washing out the unexposed parts, and finally transferring the image on to the stones or zinc plates as an ordinary lithograph. The half-tints by this process were very good, and illustrations executed by it are to be found in several existing works. The method of producing the plates, however, was much too complicated for general purposes. It had been experimented for many years, endeavouring to make the gelatin films more durable than those of Tessier de Motay. He had added gum-resins, alum, tannin and other such matters, which had the property of hardening the gelatin so as to increase the difficulty of adding sufficient to the mass in its liquid state before the whole became coagulated rendered these unmanageable. It last occurred to him that if the hardening action of light were utilized by exposing the surface next the plate to light after or before exposing the front surface to the film and the image, the plates could be used again and again for different purposes. The experiments were then tried with no chemical hardeners to it. In Tessier de Motay's process the hardening was almost absent, and the plates were consequently not durable. It is evident that to effect this one of two things had to be done. First, the plates must be abandoned, or else the film must be stripped off the plate and exposed in that manner. Albert adopted the transparent plate, and his success was assured, since instead of less than a hundred different objects being pulled from one plate he was able to take over a thousand. This occurred about 1867, but the formula was not published for two or three years afterwards, when it was divulged by Ohm and Grossman, one of whom had been employed by Albert to assist in perfecting it. At this time the process was identical to what resembled Albert's earlier efforts. The name of "Lichtdruck" was given about this time to these surface-printing processes, and Albert may be considered, if not the inventor, at all events the perfeater of the method. Another modification of "Lichtdruck" was patented in England by Ernest Edwards under the name of "heliotype."

**Woodbury Type.**—This process was invented by W. Woodbury about the year 1864, though we believe that J. W. Swan had been working independently in the same direction about the same time. In October 1864 a description of the invention was given in the *Photographic News.* Marc Antoine A. Gaudin claimed the principle of the process, insisting that it was old, and basing his pretensions on the fact that another method of taking impressions from blocks engraved by hand; but at the same time he remarked that the application of the principle might lead to important results. It was just these results which Woodbury obtained, and for which he claimed the invention of heliography, which he introduced certain modifications, the outcome being what is known as the "stannotype process," of which in 1880 he read a description before the French Photographic Society (see Process).

**Photographs in Natural Colours.**

The first notice on record of a coloured light impressing its own colours on a sensitive surface is in the passage already quoted from the *Farbenlehre* of Goethe, where T. J. Seebeck of Jena (1810) describes the impression he obtained on paper impregnated with moist silver chloride. In 1839 Sir J. Herschel (*Athenaeum,* No. 621) gave a somewhat similar description. In 1848 Edmund Becquerel succeeded in reproducing on a daguerreotype plate not only the colours of the spectrum but also, up to a certain point, the colours of drawings and objects. His method of proceeding was to give the silver plate a thin coating of silver chloride by immersing it in ferric or cupric chlorides. It may also be immersed in chlorine water till it takes a faint yellow tint, or immersed into the immersion in a solution of hydrochloric acid in water, attaching it to the positive pole of a voltaic couple, whilst the negative pole he attached to a platinum plate also immersed in the acid solution. After a minute's subjection to the current the plate took successively a grey, a yellow, a violet and a blue tint, which order was again repeated. When the violet tint appeared for the second time the plate was withdrawn and washed and dried over a spirit-lamp. In this state it
produced the spectrum colours, but it was found better to heat the plate till it assumed a rose tint. At a later date Niepce de St Victor chlorinated by chlorine of lime, and made the surface more sensitive by applying a solution of lead chloride in dextrin.

G. W. Simpson also obtained coloured images on silver chloride emulsion in collodion, but they were less vivid and satisfactory than those obtained on daguerreotype plates. Poitevin obtained coloured images on ordinary silver chloride paper by preparing it in the usual manner and washing it and exposing it to light. It was afterwards treated with a solution of potassium dichromate and cupric sulphate, and dried in darkness. Sheetsof paper thus prepared gave dark images from dark and white papers. The molecules of the molecule of the compound.

In 1880 Abney showed that the production of colour mainly resulted from the oxidation of the chloride that was formed by light. Plates immersed in a solution of hydrogen peroxide took the colours of the spectrum much more rapidly than when not immersed, and the size of the molecules seemed to regulate the colour. He found that the whole of the spectrum colours might be derived from a mixture of two or at most three sizes of molecules.

In 1841, Robert Hunt published some results of colour-photography by means of silver fluoride. A paper was washed with silver nitrate and with sodium fluoride, and afterwards exposed to the spectrum. The action of the spectrum was sketched as it passed through the violet and yellow rays, and rapidly proceeded upwards, arriving at its maximum in the blue ray. As far as the indigo the action was uniform, whilst in the violet the paper took a brown tint. When it was previously exposed to the air, a yellow space was occupied where the yellow rays had acted, a green band where the green had acted, whilst in the blue and indigo it took an intense blue, and over the violet there was a ruddy brown. In reference to these coloured images on paper, it may be noticed that silver salts affect the indigo, blue, and violet not being dealt with as a rule. An organic salt of silver is usually mixed with silver chloride paper, the organic salt being due to the sizing of the paper, which towards the red end of the spectrum is usually more evident, whilst the blue and violet is more pronounced. If a piece of ordinary silver chloride paper is exposed to the spectrum till an impression is made, it will usually be found that the blue colour of the darkened chloride is mixed with that due to the coloration of the darkened organic compound of the violet region, whereas in the blue and green this compound is absent, and the effect is due to the permanent colour from that of the darkened mixed chloride and organic compound. This naturally gives an impression that the different rays of the spectrum have a result is simply owing to the different range of sensitiveness in the two Compounds.

The silver chlorinated plate and that of true collodio-chloride, in which no organic salt has been dissolved, we have a true colour by the spectrum. There is no means of permanently fixing the coloured images which have been produced, the effect of light is to destroy them. If protected from oxygen they last longer than if they have free access to it, as is the case when the surface is exposed to air.

A method devised by Gabrielle Lippmann, of Paris, by which the natural colours of objects are reproduced by means of interference, may be briefly described as follows: A sensitive plate is placed in contact with a film of mercury, and the exposure to the spectrum, or to the ordinary object-photograph, is done by passing the plate through the back of the plate. On development, the image appears coloured when viewed at one particular angle, the colours being approximately those of the object. The necessary exposure to produce a visible image takes a longer time in the photographic plate than in which the spectrum was photographed, and a longer exposure had to be given to the red than was required for the yellow. Lippmann at first employed collodion dry plates, prepared, it is believed, with albumen, and it required considerable manipulation to bring out the colours correctly. A. Lumière used gelatin plates dyed with appropriate dyes (orthochromatic plates); the exposure was much diminished, and very excellent representations were produced of all natural colours.

The main point in aim was to prepare the plate to be of a sensitive film without any, that the exposure to the light in this case being, with, such a range of sensitiveness as is, in the sensitive salt. A formula published by Lumière seems to attain this object. Viewed directly, the developed images appear like ordinary negatives, but when held at an angle to the light the colours are vivid. They are not pure, but they give a very high quality of colour obtained by polarized light. It appears that they are produced by what may be termed 'nodes' of different-coloured lights acting within the film. Thus in photographing an ordinary object, the rays that are reflected from the silver mercury and are reflected back from it, and these, with the incident waves of light, form nodes where no motion exists, in a somewhat similar way to those obtained in a cord stretched between two points when plucked. Thus, if a negative image is formed, the other nodes are found in the thickness of the silver deposit. When white light is sent through the film after the image has been developed, theoretically only rays of the wave-lengths which formed these nodes are reflected to the eye, and thus we get an impression of colour.

Action of Light on Chemical Compounds.

Reference has been made above to early investigations on the chemical action of light. In 1777 Karl Wilhelm Scheele (Hunt's Researches in Light) made the following experiments on silver salts:

"I precipitated a solution of silver by sal-ammoniac; then I edulcorated it and dried the precipitate and exposed it to the beams of the sun for two weeks; after which I stirred the powder, and found that the salt was transformed into the same substance by a caustic spirit of sal-ammoniac (strong ammonia) on this, in all appearance, black powder, and set it by for digestion. This mepstrum dissolved a quantity of luna cornua (horn silver), though much black powder remained undisolved. The powder having been washed was, for the greater part, dissolved by a pure acid of nitr of nitric acid), which, by the operation, acquired volatility. This solution I precipitated again by means of sal-ammoniac. I found that the luna cornua acquired from the sun's light, and likewise the solution of silver poured on chalk, is silver by reduction... I mixed so much of distilled water with well-edulcorated horn silver as would just cover this powder. The half of this mixture was washed into a white crystal phial, exposed it to the beams of the sun, and showed it several times each day; the other half I set in a dark place. After having exposed the one mixture during the space of two weeks, I filtered the water standing over the horn silver, grown already black; I let some of this water fall by drops in a solution of silver, which was immediately precipitated into horn silver."

This, as far as we know, is the first intimation of the reducing action of light. From this it is evident that Scheele had found that the silver chloride was decomposed by the action of light liberating some form of chlorine. Others have repeated these experiments and found that chlorine is really liberated from the chloride; but it is necessary that some body should be present which would absorb the chlorine, or, at all events, that the chlorine should be free to escape. A tube of dried silver chloride, sealed up in vacuo, will not discolor in the light, but keeps its original white colour. A pretty experiment is to seal up in vacuo, at one end of a bent tube, perfectly dry chloride, and at the other a drop of mercury. The mercury vapour volatilizes to a certain extent and fills the tube. When exposed to light the chloride is liberated from the chloride, and colomel forms on the sides of the tube. In this case the chloride darkens. Again, dried chloride sealed up in dry hydrogen discolours, owing to the combination of the chloride with the hydrogen. Poitevin and H. W. Vogel first enunciated the law that for the reduction by light of the haloid salts of silver halogen absorbents were necessary, and it was following out this law that the present rapidity in obtaining camera images, has been rendered possible. To put it briefly, then, the visible action of light is a reducing action, which is aided by or entirely due to the fact that other bodies are present which will absorb the halogens.

In the above we have alluded to the visible results on silver salts, it is by observing that the exposure of a silver salt to light for such a brief period has an effect that of some other possible effect must be due to the same effect, that is, that any of the molecules are absolutely reduced or split up by the light. That this or such other action takes place is shown by the fact that the silver salt is capable of alkaline development, that is, the particles
which have suffered a change in their molecules can be reduced to metallic silver, whilst those which have not been acted upon remain unaltered by the same chemical agency. Two theories have been offered to explain the invisible change which takes place in the salts of silver. One is based on the supposition that the molecules of the salt can rearrange their atoms under the vibrations caused by the ether waves placing them in more unstable positions than they were in before the impact of light took place. This, it is presumed, would allow the developer to separate the atoms of such shaken molecules when it came in contact with them. The other theory is that, as in the case of the visible effects of light, some of the molecules are at once reduced and that the developer finishes the disintegration which the light has begun. In the case of the alkaline development the unaltered molecules next those primarily reduced combine with the reduced silver atom and again form an unstable compound and are in their turn reduced.

The first theory would require some such action as that just mentioned to take place and cause the invisible image formed by the shaking apart of the light-stricken molecules to become visible. It is hard to see why other unacted upon molecules close to those which were made unstable and which have been shaken and by the developer should themselves be placed in unstable equilibriums and amenable to reduction. In the second theory, called the "chemical theory," the reduction is perfectly easy to understand. Abney adopts the chemical theory as the balance of unsustained evidence is in its favour. There is another action which seems to occur almost simultaneously when exposure takes place in the absence of an active halogen absorbent, as is the case when the exposure is given in the air, that is, an oxidising action occurs. The molecules of the altered haloid salts take up oxygen and form oxides. If a sensitive salt be briefly exposed to light and then treated with an oxidizing substance, such as potassium dichromate, potassium permanganate, hydrogen peroxide, ozone, an image is not developed, but remains unaltered, showing that a change has been effected in the compound which under ordinary circumstances is developable. If such an oxidized salt be treated very cautiously with nascent hydrogen the oxygen is withdrawn and the image is again capable of development.

Spectrum Effects on Silver Compounds.—The next inquiry is as to the effect of the spectrum on the different silver compounds. We have already described Seebeck's (1810) experiments on silver chloride with the spectrum whereby he obtained coloured photographs, but Scheele in 1777 allowed a spectrum to fall on the same material, and found that it blackened much more readily in the violet rays than in any other. Senebier's experiments have been already quoted. We merely mention these for their historical interest, and pass on to the study of the action of the spectrum on different compounds by Sir J. Herschel (Phil. Trans., 1849). He describes many experiments, which have become the foundation of nearly all subsequent researches of the same kind. The effects of the spectrum have been studied by various experimenters since that time, amongst whom we may mention Edmond Becquerel, John William Draper, Alphonse Louis Poitevin, H. W. Vogel, Victor Schumann and W. de W. Abney. Fig. 1 is compiled from a cut which appeared in the Proc. Roy. Soc. for 1882, and shows the researches made by Abney as regards the action of the spectrum on the three principal haloid salts of silver. No. 7 shows the effect of the spectrum on a peculiar modification of silver bromide made by Abney, which is seen to be sensitive to the infra-red rays.

Effect of Dyes on Sensitive Films.—In 1874 Dr H. W. Vogel of Berlin found that when films were stained with certain dyes and exposed to the spectrum an increased action on development was shown in those parts of the spectrum which the dye absorbed. The dyes which produced this action he called "optical sensitizers," whilst preservatives which absorbed the halogen liberated by light be called "chemical sensitizers." A dye might, according to him, be an optical and a chemical sensitiser. He further claimed that, if a film were prepared in which the haloid soluble salt was in excess and then dyed, no action took place unless some "chemical sensitiser" were present. The term "optical sensitiser" seems a misnomer, since it is meant to imply that it renders the salts of silver sensitive to those regions of the spectrum to which they were previously insensitive, merely by the addition of the dye. The idea of the action of dyes was at first combated, but it was soon recognized that such an action did really exist. Abney showed in 1875 that certain dyes combined with silver and formed true coloured organic salts of silver which were sensitive to light, and Dr Robert Amory went so far as to take a spectrum on a combination of silver with eosin, which was one of the dyes experimented upon by J. Waterhouse, who had closely followed Dr Vogel, and proved that the spectrum acted simply on those parts which were absorbed by the compound. Abney further demonstrated that, in many cases at all events, the dyes were themselves reduced by light, thus acting as nuclei on which the silver could be deposited. He further showed that even when the haloid soluble salt was in excess the same character of spectrum was produced as when the silver nitrate was in excess, though the exposure had to be prolonged. This action he concluded was due to the dye.

Correct Rendering of Colours in Monochrome.—In Plate IV., fig. 14 the sensitiveness of a plate stained with homocoll is shown, and it is evident that as it is sensitive throughout the visible spectrum there must be some means of cutting off by a transparent screen so much of the spectrum luminosity at different parts that every colour having the same luminosity to the eye shall be shown on a negative of equal density. When this is done the relative luminosities of all colours will be shown by the same relative densities or in a print by different depths of greys. Abney devised a sensimeter which should be used to ascertain the colour of the screen that should be employed. By proper means the luminosity of the light of day coming through a red, a green, a blue and an orange glass can be very accurately measured; if ½-in. squares of these colours glasses, together with a white glass of the same area, be placed in a row and cemented on white glass, we have a colour screen which we can make available for finding the kind of light-filter to be employed. This is readily done by reducing the luminosity of the light coming through all the glasses to that of the luminosity of the light coming through the blue glass. If the luminosity of the blue be 5 and that of the white light 100, then the luminosity of the former must be reduced to 5/7 of its original value, and so with the other glasses. The luminosity of the light coming through each small glass square can be made equal by rotating in front of them a disk in which apertures are cut corresponding to the reduction required. The

blue glass, for instance, would not be covered by the disk at all, while opposite the white square the disk would have an aperture of an angle of 45°. When a plate is exposed behind the row of glass squares, with the light passing through the rotating disk, having the appropriate apertures for each glass, the negative obtained would under ordinary conditions, show square patches of very different opacity. A light-filter of some transparent colour, if placed in the path of the light, will alter the opacities, and eventually one can be found which will only allow such coloured light to be transmitted as will cause all the opacities in the negative to be the same. As the luminosities of the white light passing through the glasses are made equal, and as the photographic deposits are also rendered equal, this light-filter, if used in front of the camera lens, will render all coloured objects in correct monochrome luminosity. Another plan, based on the same principles, is to use segments of annuluses of vermilion, chrome yellow, emerald green, French blue and white on a disk, and to place the annuluses with black segments, the amount of black depending on the luminosity of the pigments, which can be readily measured. When the disk is rotated, rings of colour, modified in brightness by black, are seen, and each ring will be of the same luminosity. As before, a screen (light-filter) to be used in front of the lens must be found which will cause the developed images of all the rings to appear of equal opacity. It must be remembered that the light in which the object is to be photographed must be the same as that in which the luminosity of the glasses or pigments is measured.

Action of Light on Uranium.—The salts of uranium are affected by light in the presence of organic matter, and they too are only acted upon by those rays which they absorb. Thus nitrate of uranium, which shows, too, absorption-bands in the green blue, is affected more where these occur than in any other portion of the spectrum.

Some salts of mercury, gold, copper, lead, manganese, molybdenum, platinum, vanadium, are affected by light, but in a less degree than those which we have discussed. In the organic world there are very few substances which do not change by the continuous action of light, and it will be found that as a rule they are affected by the blue end of the spectrum rather than by the red end (see PHOTOCHEMISTRY).

The following table gives the names of the observers of the action of light on different substances, with the date of publication of the several observations. It is nearly identical with one given by Dr Eder in his Geschichte der Photo-Chemie.

Fig. 2.—The top letters have reference to the Fraunhofer lines; the bottom letters are the initials of the colours. The relative sensitiveness is shown by the height of the curve above the base-line; the various parts of the spectrum on potassium bichromate. If other bichromates are employed, the action will be found to be tolerably well represented by the figures. No. 1 is the effect of a long exposure, No. 2 of a shorter one. It should be noticed that the solution of potassium bichromate absorbs those rays alone which are effective in altering the bichromate. This change is only possible in the presence of organic matter of some kind, such as gelatin or albumen.

Action of the Spectrum on Asphalum.—This seems to be continued into and below the red, the blue rays, however, are the most effective. The action of light on this body is to render it less soluble in its usual solvents.

Action of the Spectrum on Salts of Iron.—The commonest ferric salt in use is the oxalate, by which the beautiful platino type prints are produced. We give this as a representation (fig. 3) of the spectra obtained on ferric salts in general. Here, again, we have an example of the law that exists as to the correlation between absorption and chemical action. One of the most remarkable compounds of iron is that experimented upon by Sir J. Herschel and later by Lord Rayleigh, viz. ferrocyanide of potassium and ferric chloride. If these two be brushed over paper, and the paper be then exposed to a bright solar spectrum, action is exhibited into the infra-red region. This is one of the few instances in which these light-waves of low refrangibility are capable of producing any effect. The colour of this solution is a muddy green, and analysis shows that it cuts off these rays as well as generally absorbs those of higher refrangibility.

Effect of Hydrogen Peroxide on Sensitive Plates.—Dr W. J. Russell made a series of experiments on the effect of exposure of sensitive plates to the action of vapours and gases for long periods. It has long been known that contact of plates with such substances as wood caused a sensitive surface to show "fog" on development. By a somewhat exhaustive series of experiments, Russell showed that the probable cause of this fog is hydrogen peroxide, since substances which favoured its formation produced the same effect. This is somewhat remarkable, as the same substance will completely destroy the effect that light has had on a sensitive plate; indeed, it affords one way of destroying a light image on a sensitive collodion plate. The experiments of Russell give a warning to store exposed plates for brief periods. It appears that negatives wrapped in paraffin paper are secure from this danger.

The Application of Photography to Quantitative Measures.—In order to employ photography for the measurement of light it was necessary that some means should be devised by which the opacity of the deposit produced on the development of a plate could be determined. It is believed that in 1874 the first attempt was made by sir W. Alney to do this. In the Phil. Mag. he showed that density could be measured by means of an instrument, the diaphanometer, he had devised, in which transparent
black wedges were used to make matches between the naked light and the same light after passing through the photographic opacity that had to be measured. In 1887, owing to the perfecting of the rotating sectors, which could be made to increase or diminish the apertures at pleasure during its rotation, the measurement of opacities became easy. The Rumford method of comparing the light through the deposit with the naked beam, using the sectors to equalize the illumination, was adopted, the deposit being placed between the light and the screen, the comparison light being a beam reflected from the same light on to the screen.

Owing to the fact that photographic deposit scatters light more or less, the opacities measured by this plan were slightly different than was shown when such opacities were to be used for contact printing. The final plan adopted by Abney was to place the part of the plate carrying the deposit to be measured behind a screen, and D D a dull black card with an aperture cut in it which may be of any desired shape. This aperture was covered with transparent paper, as was also a portion B, the same size as A, but pasted on the black card itself. Light thrown from behind A would be matched with light thrown on to B from the front when the deposit was removed.

With this screen accurate measures of printing densities can be made, and it can also be used in the determination of the comparative photographic brightness of the light issuing from different objects. For instance, the relative brightness of the different parts of the corona as seen in a total eclipse can be readily determined if a "time scale" of gratings is impressed on the plate on which it is taken. Both scale and streamer can then be enlarged optically and thrown on the part of the screen A. The measures of the streamer densities can then be directly compared with the densities of the scale, and the relative "photographic" brightness of the different parts of the streamer ascertained by comparison with this scale also.

The same method of measurement was adopted in ascertaining quantitatively the sensibility of the spectrum of objects and of plates in which dyes are present. The figures on PI. IV show reproductions of plates which were exposed to the spectrum. No. 1 is a continuous spectrum taken with the electric light; no. 7 is an impressed continuous spectrum; no. 8 shows the bright line spectrum of metals; no. 3 the line spectrum of volatilized lithium and sodium to indicate the position of the spectrum colours. Nos. 4 and 2 are the absorption and fluorescent spectra of eosin. No. 5 is the gradation scale formed by a bromogelatin. "Seed" plate stained with hemocoll, a cyanine derivative sensitive to the red; no. 6 is a similar scale formed by an unstained plate. The small numbers placed below the different bands show an empiric scale which is made to apply to each of them. The first step is to measure its different parts, and also the curve of sensibility of the plate to the different parts of the spectrum. This last is derived from a comparison of the measured densities with those of thegradation scale.

**Measurement of the Rapidity of a Plate.**—The first attempt that was made to ascertain the rapidity of a plate was by Abney (Phil. Mag. 1874), who demonstrated that within limits the transparency of deposit is always the same.

The last formula has been accepted for general use, though it is believed that it is not absolutely correct, though very approximately true and sufficiently near to be of practical value. This belief is based on the further researches described below.št

In Fig. 4, Mr. W. Abney pointed out that the speed of a plate could be determined by the formula $T = E_0 \times (log E + C)^2$, where $T$ is the transparency, $E$ is the exposure (or time of exposure $X$ intensity of light acting), and $C$ a constant. If the abscessae (exposures) are plotted as ordinates, $Y$ becomes the abscissa, and the formula takes the same form as that of the law of error, which has a singular point, a tangent through which lies closely along the curve and cuts the axis of $Y$ at a point which has a value of $2/E_0$. If the total transparency be unity, this ordinate has a value of $1-25$, the singular point having a value of $0-066$. The ordinates of the zero point of the curve will be where the tangent to the singular point cuts the line drawn at $2121$. The difference between the measurements of this zero point for two kinds of plates (i.e. C in the formula) from the points in the abscessae marking the same exposure, will give the relative sensitiveness of the two plates in terms of $log x^2$.

In 1890 Hurter and Driffield (Journ. Soc. Chem. Ind. Jan. 19, 1891) worked out a empirical formula connecting the exposure $E$ with the density of deposit, which in an approximate shape had the form $D = \log (E/H)$, where $D$ is the density of deposit (or log $1/T$), $E$ the "inertia" of the plate, $T$ the transparency of the deposit. In the customary way a spectrum of a plate is exposed to a light and then measured, both for distance and for a fixed time, and another small portion to the same light for double the time, and so on. By measuring the densities of the various deposits and constructing a curve, a large part of the phenomena associated with the light can be measured, and the production of the straight portion to meet the axis of $X$ will give the relative sensitiveness of different plates by the distance of the intersection from the zero point $L$. (See also Exposure Methods, below, under § 1, APPARATUS.)

**Effect of Temperature on Sensitiveness.**—In 1876 Abney showed that heat apparently increased, while cold diminished, the sensitiveness of a plate, but the experiments were rather of the qualitative than the quantitative order. In 1883, from fresh experiments, he found that the effect of a difference in temperature of some $40^\circ$ C. invariably caused a diminution in sensitiveness of the sensitive salt at the lower temperature, a plate often requiring more than double the exposure at a temperature of about $-18^\circ$ C. than it did when the temperature was increased to $+33^\circ$ C. The general deduction from the experiments was that increase in temperature involved increase in sensitiveness so long as the constituents of the plate (gelatin, &c.) were unaltered. Sir James Dewar stated at the Royal Institution in 1866 that at a temperature of $-16^\circ$ C. certain sensitive films were reduced in sensitiveness to less than a quarter of that which they possess at ordinary temperatures. It appears also, from his subsequent inquiries, that when the same films were subjected to the temperature of liquid hydrogen ($-252^\circ$ C.) the loss in sensitiveness becomes asymptotic as the absolute zero is approached. Presumably, therefore, some degree of sensitiveness would still be preserved even at the absolute zero.

**Effect of Small Intensities of Light on a Sensitive Salt.**—When a plate is exposed for a certain time to a light of given intensity, it is commonly said to have received so much exposure (E). If the time be altered, and the intensity of the light also, so that the exposure (time $X$ intensity) is the same, it was usually accepted that the energy expended in doing chemical work in the film was the same. A series of experiments conducted under differing conditions has shown that such is not the case, and that the more intense the light (within certain limits) the greater is the chemical action, as shown by a development of the plate.

Fig. 6 illustrates the results obtained in three cases. The exposure $E$ is the same in all cases. The curves are so drawn that the scale of absissae

---

1. Those applicable to the correction of star magnitudes as determined by photography have been verified and confirmed by Schwarzschild, Michalke and others.

is the intensity of the light in powers of $-\lambda$, and the ordinates show the percentages of chemical action produced. If the chemical action remained the same when the intensity of light was reduced, $E$ remaining the same, each of the curves would be shown as a straight line at the height of 100, which is the transparency of deposit with the unit of light. As it is, they show diminishing percentages as the light intensity is diminished.

Thus, when the intensity of the light is reduced to $\frac{1}{\sqrt{10}}$ of the original, and the time of exposure is prolonged 64 times, the useful energy expended on a lantern plate is only 50% of that expended when the light and time of exposure are each unity. In the cases to which the diagram refers, the light used was a standard amyl acetate lamp, and the unit of intensity taken was this light at a distance of 2 ft. from the plate, and the unit of time was 10 seconds. The lamp being moved to 16 ft. from the plate, gave an intensity of $\frac{1}{4}$, the unit of time of exposure had to be increased to 640 seconds, so that $E$ was the same in both cases. Further, it was found that when the times of exposure on different parts of the plate were successively doubled, light at a fixed distance being used for one series, and altered for a second series, the slopes of the curves of transparency (i.e. the gradation) were parallel to one another. This investigation is of use when camera images are in question, as the picture is formed by different intensities of light, not very different from those of the amyl acetate lamp, the time of exposure being the same for all intensities. The deductions made from this investigation are that with a slow plate the energy expended in chemical action is smaller as the intensity is diminished, while with a quick plate the variation is much less. As a practical deduction, we may say that to obtain proper contrast in a badly lighted picture it is advisable to use a slow plate.

**Effect of very Intense Light on a Sensitive Salt.**

—Another investigation was made as to the effect of very intense light on sensitive surfaces. In this case a screen of step-by-step graduated opacities was made use of, and plates exposed through it to the action of lights markedly differing in intensity, one being of the amyl acetate lamp, another that of the arc light, and a third the light emitted from the spark of a Wimshurst machine. The exposures were so made that one of the opacities produced on the plate from exposure to each source of light was approximately the same. The unit of illumination of light is, of course, in each case widely different. The slope of the curve due to the spark light is less steep than that due to the arc light, and the latter, again, is much less steep than that due to the amyl acetate lamp. A further investigation was made of the effect of increasing the time of exposure when the intense light was diminished, and it was found that with all plates the useful chemical energy acting on a plate was least with the most intense light, but increased as the intensity diminished, though the time was correspondingly increased. This is the reverse of what we have recorded as taking place when a comparatively feeble light was employed. Further, it was proved that the variation was greatest in those plates which are ordinarily considered to be the most rapid. It follows, therefore, that there is some intensity of light when the useful chemical energy is at a maximum, and that this intensity varies for each kind of plate.

**Intermittent Exposure of a Sensitive Salt.**—The same investigator has shown that, if a total exposure is made up of intermittent exposures, the chemical action on a sensitive salt is less than it is when the same exposure is not intermittent. It was also proved that the longer the time of rest between the intermittent exposures (within limits) the less was the chemical reaction. We may quote one case. Exposures were first made to a naked light, and afterwards to the same light for six times longer, as a rotating disk intervened which had 12 apertures of 5° cut in it at equal intervals apart, and 720 intermittent exposures per second were given. The plate was moved to different distances from the light, so that the intensity was altered. The apparent loss of exposure by the intervention of the disk increases as the intensity diminishes, the ratios of the chemical energy usefully employed of the naked light exposure to that of the intermittent exposures being:

These results appear to be explicable by the theoretical considerations regarding molecular motion.

**Effect of Monochromatic Light of Varying Wave-lengths on a Sensitive Salt.**—It has been a subject of investigation as to whether the gradation on a plate is altered when exposures are made to lights of different colours; that is to say, whether the shades of tone in a negative of a white object illuminated by, say, a red light, would be the same as those in the negative if illuminated by a blue light. Abney announced that the gradation was different; and, quite independently, Chapman Jones made a general deduction for isochromatic plates that, except with a certain developer, the gradation was steeper (that is, the curve shown graphically would be steeper) the greater the wave-lengths of the light to which the sensitive salt was subjected. For plates made with the ordinary haloid salts of silver Chapman Jones's deduction requires modification. When monochromatic light from the spectrum is employed, it is found that the gradation increases with wave-lengths of light which are less, and also with those which are greater, than the light whose wave-lengths has a maximum effect on the sensitive salt experimented with. Thus with bromo-iodide of silver the maximum effect produced by the spectrum is close to the blue lithium line, and the gradation of the plate illuminated with that light is less steep than when the light is spectrum violet, green, yellow or red. From the red to the yellow the gradation is much the steepest. Whether these results have any practical bearing on ordinary photographic exposures is not settled, but that they must have some decided effect on the accuracy of three-colour work for the production of pictures in approximately natural colours is undoubted, and they may have a direct influence on the determination of star magnitudes by means of photography.

**Reproduction of Coloured Objects by means of Three Photographic Positives.**—Ives's Process.—A practical plan of producing images in approximately the true colours of nature has been devised by preparing three positives of the same object, one

illuminated by a red, the other by a green, and the third by a blue light; the images from these three transparencies, when viewed simultaneously, produced the sensation of colours.

The principle was scientifically and practically worked out by F. E. Ives of Philadelphia, though in France and elsewhere it had been formulated especially by Haroun d'En Croz.

The following description may be taken as that of Ives's process: by the trichromatic theory of colour-vision every colour in nature can be accounted for by the mixture of two or three of the three-colour sensations, red, green and blue, to which the eye is supposed to respond. Thus a mixture of a red and green sensation produces the sensation of yellow; of a green and blue, that of a blue-green; of red and blue, that of purple; and of all three, that of white. For the sensations we may substitute those colours which most nearly respond to the theoretical sensations without any material loss of purity in the resulting sensation. We must take the spectrum of white light as the only perfect scale of pure colours. It has been proved that the red sensation in the eye is excited by a large part of the visible spectrum, but with varying intensities. If, then, we can on a photographic plate produce a development of properly selected latent negatives of the kind appropriate to the colours and position to the amount of red stimulation excited in those regions, we shall, on illuminating a transparent positive taken from such a negative with a pure red light, have a representation of the spectrum such as would be seen by an eye which was only endowed with the sensation of red. Similarly, if negatives could be taken to fulfill the like conditions for the green and for the blue sensations, we should obtain positives from them which, when illuminated by pure green and blue light respectively, would show the spectrum as seen by an eye which was only endowed with a green or a blue sensation. Evidently if by some artifice we can throw the coloured images of these three positives on a screen, superposing them one over the other in their proper relative positions, the spectrum will be reproduced, for the overlapping colours, by their variation in intensity, will form the colours intermediate between those used for the illumination of the positives. For the purpose of producing the three suitable negatives of the spectrum, three light-filters, one transmitting the image has to pass before reaching the photographic plate, have to be found. With all present plates these are compromises. Roughly speaking, the screens used for taking the three negatives are an orange, a bluish-green and a blue. These transmit those parts of the spectrum which answer to the three sensations. When these are obtained an image of a coloured object can be reproduced in its true colours.

Abney devised senosimeters for determining the colours of the screens to be placed before the lens in order to secure the three-colour negatives which should answer these requirements. Their production depends upon the same principles indicated as necessary for the correct rendering in monochrome of a coloured object. When the sensitometer takes the form of glasses through which light is transmitted to the plate, the luminosities of the coloured lights transmitted are determined, and also their percentage composition in terms of the red, green, and blue lights, and these are deduced from the luminosities in terms of red, green and blue. For ascertaining what screen should be used to produce the red negative the luminosity transmitted through each glass is so adjusted that the luminosities of the corresponding positives may be a bluish-green on a disk with correct apertures cut out close to the row of glasses. This gives a sensitometer of equal red values. A coloured screen has to be found which, when placed in front of the lens, will cause the other part of the plate corresponding to each white portion of the image to pass through the glass, to be the same throughout. This is done by trial, the colour being altered till the proper result is obtained. In a similar way the "green" and "blue" screens are determined. Coloured negatives of the disk can also be employed, also in the paragraph on the correct rendering of colour in monochrome. As to the camera for the amateur, whose plates are not as a rule large, all of the three negatives should be obtained on one plate, since only one negative can be developed and the densities increased together. (For commercial work the negatives often cannot be taken on the same plate, as it would make the plate too large to manipulate.) The camera may be of an ordinary type, with a revolving back, bringing successively three different portions of the plate opposite the lens. It is convenient to have a slide, in front of which a holder containing the three screens can be fixed, which will then be close to the plate; such a one has been devised by E. Sanger-Shepherd. The light passes through them one by one as the plate is moved into the three positions. The three exposures are given separately, after which the plate is ready for development. The three separate exposures are, however, a source of trouble at times, particularly in the case of landscapes, for the light varies with the skylight conditions, and the order in which the pictures would show variations which should not exist. Sanger-Shepherd has a "one-exposure" camera by which the three images are thrown side by side on the plate. Thus any movement in the picture affects all three negatives alike. Abney has also introduced a "one-exposure" camera which takes in a larger angle than that of Sanger-Shepherd. The next point is the exposures which should be given through each screen. This depends largely on the position in the picture of the different negatives.

Joly's Process.—Professor J. Joly, of Dublin, in 1897 introduced a process by which an image in approximately natural colours could be thrown upon a screen by an optical lantern, only one transparency being employed, instead of three, as in the Ives process. A "taking" screen was ruled with alternating orange, blue-green and bluish-grey, in the proportion of blue to orange and yellow, 2 to 3 or 4. When such a screen was placed in front of a sensitive plate in the camera, and exposure made to the image of a coloured object, there were practically three negatives on the same plate, each being confined to the area occupied by lines of the same colour. The shades of colour and the depth of the colours used in ruling depended on the brand of plate. When a perfect trine negative was obtained, a transparency was made from it, and in contact with this was placed a ruled screen with lines the same distance apart, with the coloured and the non-coloured images having separate positions on the film. When such a screen was placed in front of a sensitive plate in the camera, and exposure made to the image of a coloured object, there were practically three negatives on the same plate, each being confined to the area occupied by lines of the same colour. The shades of colour and the depth of the colours used in ruling depended on the brand of plate. When a perfect trine negative was obtained, a transparency was made from it, and in contact with this was placed a ruled screen with lines the same distance apart, but of the colours corresponding to the three colour sensations. The screen was then cut and another one placed to fall on the image taken through the orange lines, the green on that of the blue-green, and the blue or violet on that of the blue. On the screen there are practically three differently coloured images shown by one transparency. The eye blends the different colours together and a picture is seen in approximately the correct colours of the original.

Autochrome.—A very remarkable process, founded on J. Joly's process, was introduced in 1907 by A. Lumière et ses Fils de Lyons. Starch grains of very minute size, some of which were dyed with a red stain, a second portion with a green, and a third portion with a blue, are mixed together in such proportions that a fine layer of them appears grey when viewed by transmitted light. Under a magnifying glass the grains are coloured, but owing to the want of focus in the eye the colours blend one with the other. Such a layer is embedded on the surface of a glass plate in a waterproof vehicle, and a film of sensitive emulsion is placed on it. In some cases another layer, which has not been published, covers this layer. When such a plate is placed in the camera, with the back of the plate next the lens, the light passes through the coloured granules, and again we have three negatives on one plate, but instead of each negative being represented by lines as in the Joly process they are represented by dots of silver deposit. Owing to the way in which the three-coloured film is prepared, it is evident that a positive taken from such a negative could not be backed with granules of the right colour; as the granules are placed at random in the layer. Lumière, to overcome this difficulty, converted the negative into a positive in a very ingenious way. The plate was developed with pyrogallic and ammonia in the usual way, but instead of fixing it it was plunged into a solution of potassium permanganate and sulphuric acid. This dissolved all the silver that had been deposited during development and left a film of unaltered silver salt. On looking through the plate the colours of the coloured layer coming through the different dots where the silver was at
first deposited appeared in view, and the image was the image in colour of the object photographed. The plate after being washed was taken into the light and redeveloped with an alkali-line developer, which converted the sensitive salt of silver to the metallic state. The image now consisted of black particles of silver and the coloured image. The plate was next fixed in hypophosphate of soda to remove any unreduced silver salt that might be left, and the picture after washing was complete. The coloured image so obtained is a very close representation of the true colours, but as the “taking” screen is the same as the “viewing” screen some little variation must result.

Positives in Three Colours.—Ives was the first to show that a transparency displaying approximately all the colours in nature could be produced on the same principles that underlie the three-colour printing. This he effected by printing each of the three negatives, produced for his triple projection process as already described, on gelatine films sensitized by bichromate of potash. Each of the three transparent films was dyed with a colour complementary to the colour of the light which he transmitted through the positives when used for projection. Thus the “red” positive he dyed with a blue-green dye, the “green” positive with a purple dye, and the “blue” positive with a yellow dye. These three films, when superposed, gave the colours of the original object. Sanger-Shepherd has made the process a commercial success (see Process) and produces lantern slides of great beauty, in which all colours are correctly rendered. Instead of using a dye for the “red” transparency, he converts the silver image of a positive image into an iron salt resembling Prussian blue in colour. (W. DE W. A.)

II. PHOTOGRAPHIC APPARATUS

Photographic apparatus consists essentially of the camera with lens and shutter, lens shutters, exposure meters, prepared plates for the production of negatives or transparencies, sensitive papers and apparatus for producing positive prints, direct or by enlargement. Besides these there are many subsidiary accessories.

Since the introduction of highly sensitive dry plates and their extended use in hand cameras, the art and practice of photography have been revolutionized. Numerous special forms of apparatus have been created suitable for the requirements of the new photography, and their manufacture and sale have become important industries. The value of the exports of photographic materials from the United Kingdom in 1906 was £22,716. The most important improvement has been in the construction of anastigmat lenses, which, having great covering power, flatness of field, and freedom from astigmatism, can be worked with very much larger apertures than was possible with the earlier forms of rectilinear or applanatic lenses. The increased rapidity of working thus gained has rendered it easy to photograph objects in very rapid motion with great perfection. This has encouraged the construction of the very light and compact hand cameras now so universally in use, while, again, their use has been greatly simplified by improvements in the manufacture of sensitive plates and films and the introduction of light, flexible, sensitive films which can be changed freely in daylight. The introduction in 1907 of Messrs Lumière’s “Autochrome” process of colour photography has also been a great advance, tending to popularize photographic work by the facility it offers for reproducing objects in the colours of nature.

The Camera.

Historical.—The camera obscura (q.v.) was first applied to photographic use by Thomas Wedgwood between 1792 and 1802. No description of his camera is available, but it was probably one of the sketching cameras then in use. In 1812 W. H. Wollaston found that by using a meniscus lens with a concave surface towards the object and the convex towards the screen, a diaphragm being placed in front, the projected image of the camera obscura was greatly improved in sharpness over a larger field. The first photographic lenses made by V. and Ch. L. Chevalier in Paris (1830–1840) were on this principle. The photographic camera in its simplest form is a rectangular box, one end of which is fitted to carry a lens and the opposite one with a recess for holding the focusing screen and plate holders, these ends being connected by a rigid or expanding base-board and body, constructed to keep out all light from the sensitive plate except that passing through the lens. In 1816 Joseph Nicéphore Niepce, of Chalon-sur-Saône, for his photographic experiments made a little camera, or artificial eye, with a box six inches square fitted with an elongated tube carrying a lentil-lar glass. There are now in the Chalon Museum cameras of his with an iris diaphragm for admitting more or less light to the lens; some with an accordion bellows, others with a double expanding rigid body for adjusting the focus. The iris diaphragm was adopted later by Chevalier for his photographic lenses. In 1835 W. H. Fox Talbot constructed simple box cameras for taking views of his house on sensitive paper, and claimed them as the first photographs of a building (Phil. Mag. 1839, 14, p. 206). Fr. von Kobell and C. A. Steinheil, early in 1839, made a camera with an opera glass lens for taking landscapes on paper. Later in 1839 J. W. Draper successfully used a camera for his daguerreotype experiments made of a spectacle lens, 14 in. focus, fitted into a cigar box. He also constructed a camera and fixed a diaphragm of a lens. Similar cameras were constructed by A. T. Wolcott (1840) and R. Beard (1841) for reversing the image in daguerreotype portraits. They have also been recommended by V. Zenger (1875) and D. Mach (1890) for scientific work.

L. J. M. Daguerre’s camera, as made by Chevalier in 1839 for daguerreotype, was of Niepce’s rigid double body type, fitted with an achromatic meniscus lens with diaphragm in front on Wollaston’s principle, the back part with the plate moving away from the lens for focusing, and fixed in its place with a thumbscrew. This expanding arrangement enabled lenses of different focal lengths to be used. With modifications cameras of this type were in use for many years afterwards for portrait and studio purposes. For work in the field they were found inconvenient and many more portable forms were brought out, among them G. Knight’s and T. Oettewil’s single and double folding cameras (1853), made collapsible with hinges, so as to fold on to the base-board. Cameras with light bodies made of waterproof cloth, &c., also came into use, but these were superseded by cameras with collapsible bellows-body of leather, which, invented by Niepce, were used in France, in 1859, by Baron A. P. de Séguier and others for daguerreotype. The first record of them in England is, apparently, J. Atkinson’s portable stereoscopic camera of parallel-side bellows form (Ph. Journ. 1857, 3, p. 261), which was soon followed by C. T. H. Kinnear’s lighter conical form, made by Bell of Edinburgh (Ph. Journ. 1858, 4, p. 106). They have since been made in various patterns, conical, oblong and square, by P. Meagher, G. Hare and others, and are still, in modified forms, in general use as studio, field or hand cameras. When wet collodion plates were used many cameras were fitted with arrangements for developing in the field.

Information on these and other early cameras will be found in the photographic journals, in C. Fabre’s Traité encyclopédique de photographie, in H. Le Fèvre’s Ausführliches Handbuch der Photographie, 2nd ed., vol. i., pt. ii.

The distinctive feature of present day photography is the world-wide use of the hand camera. Its convenience, the ease with which it can be carried and worked, and the remarkably low prices at which good, useful cameras of the kind can be supplied, concurrently with improvements in rapid sensitive plates and lenses, have conduced to this result. It has also had a valuable educational influence in quickening artistic perception and scientific inquiry, besides its use in depicting scenes and passing events for historical record. Small portable cameras had been made by B. G. Edwards (1853), T. Scaife (Pistolgraph, 1858), A. Bertsch (1860), T. Oettewill (1861), and others, but it was not until rapid gelatin dry plates were available in 1885 that T. Bolas brought out his “detective” camera (Ph. Journ. 1881, p. 59). It consisted of a double camera (one as finder, the other for taking the picture) enclosed in another box, suitably covered, which also contained the double-plate carriers and had apertures

(1887), R. Krugener's camera (book form, 1888), and others in
collapsible or box forms disguised as books, watches, &c, but

they did not come into general use before 1888, when the Eastman Company of Rochester, U.S.A., brought out their very
portable roll-film cameras, now known under the trade name of
" Kodak."
The manufacture of these and other light hand
cameras has since become a very important and flourishing
industry in Great Britain, Germany, France and the United
States.
It is noteworthy that the most modern form of hand
camera, the reflex, goes back to an early type of portable camera
obscura, figured by Johann Zahn in 1686, in which a mirror was
used for reflecting the image on to a horizontal focusing screen,
At the same time reversing it. The first photographic camera on
this principle was T. Sutton's (i860), which has served as a basis
A. D. Loman's (1889) and
/or many subsequent developments.
R. Krugener's (1891) were early examples of the hand camera
type, but great improvements have since been made.

Modern cameras differ so much in details of improved construction
that only a few of the more important requirements can be noticed.
A camera should be well and strongly made of seasoned wood or
of metal, perfectly rigid when set up, to avoid any shifting of the
axis of the lens in respect to the sensitive plate.
The front and
back of the camera should normally be vertical and parallel, and
the axis of the lens perpendicular to the centre of the plate, but
arrangements are usually made by vertical and lateral adjustments
on the camera front for raising the lens to take in less foreground
or vice versa, or for moving it right or left, the latter becoming a
vertical movement when the camera has to be turned on its side.
In the Adams " Idento'" camera the lens and finder can be rotated
together on the rising front according as the camera is used horizontally or vertically, the finder showing in either case the identical
view projected on the plate. The best modern field cameras are
fitted with a swing-back or swing-front and sometimes with both.
A swing-back is necessary for bringing back the plate to the vertical
position, so as to prevent convergence of vertical lines, when the
rising swing-front, in which the lens
camera has to be tilted.
is tilted, answers the same purpose, provided the camera is kept
level.
If further tilting is necessary, when taking high buildings
&c, the swing-back and front may both be required, but must be
kept vertical and parallel and the effect is that of an abnormal
Many modern cameras are fitted with a double rising
rising front.
The vertical and side swings are also useful for equalizing
front.
the definition of objects at different distances from the camera,
but they alter the perspective. These swing-movements should
Creferably be round the central horizontal or vertical axis of the
ack or front, but are frequently effected by simple inclination of
the back or lens front on a hinge. When the rising front is used
a lens of extended covering power is desirable, and it may be necessary to stop it down to obtain good definition over the extended
area of the picture. A slight inclination of the lens may also be
The camera and plate carriers
useful in readjusting the focus.
must be perfectly light-tight and all inner bright surfaces made
dead black to prevent reflections from bright spots being thrown
on the plate. The black varnish used, preferably of shellac and
lampblack in spirit, must have no deleterious effect on the plates.
Although the weight and bulk are increased it is convenient to have
the camera square and fitted with a reversible back, so that the
greatest length of the plate may be horizontal or vertical, as desired.
Many cameras are fitted with revolving backs to be used in either
position.
In some French cameras the back part of the camera
with the bellows is reversible, to be used upright or horizontal.
Focusing. The earlier cameras were focused by drawing out
the back and clamping it with a thumb-screw working in a slot in
the base-board. When bellows cameras were introduced they were
focused by an endless screw, and these are still used for large copying cameras. Most modern cameras are fitted with rack and pinion
movements working either in front or at the back of the camera or

scale attached to the base-board.
by measurement.
In hand cameras with fixed infinity focus,
the necessary adjustments for distance of near objects are made on
the lens mount. The focusing screen may be ruled with parallel
cross lines for purposes of measurement, and as a check on the
vertically of the camera when photographing buildings or other
objects with vertical lines. The distance of the lens from the focusing screen and from the sensitive plate in the dark slide must coincide
exactly.
This can be tested by measurement or by focusing a

bright, well-defined object on the screen and then on a groundlevel or
glass plate placed in each of the slides to be examined.
other means of showing that the camera is level and the plate vertical
should be attached to the camera, also a view meter or finder,
showing the exact extent of the picture on the focusing glass. In
the view meter the picture is viewed directly through a pin-hole
mounted at the back of the camera as it appears in a frame with
cross wires on the rising front, adjusted to the size of the plate and
the **>cus of the lens. Finders are practically small reflex cameras,
and a reduced image is seen reflected from a mirror or prism.
rectangular concave glass mounted on the camera is also a convenient form, it can be combined with a mirror for vertical observation, and in Watson's new form is also arranged as a level and
telemeter (B. J. A. p. 724, 1908). The image seen in the finders

A

A

should correspond exactly with that on the plate. When the rising
is used special arrangements have to be made to ensure the
correspondence of the images in the finder and on the groundglass.
This is done in the " Adams Identoscope " (1908), which
is fitted to the swing front and adjusted by a lever to follow the
movement of the lens.
The dark-slides or backs, holding
Plate-holders or Dark-slides.
sensitive plates, are made either single or double, the former usually
for wet plates, the latter for dry plates. The ordinary book-form
double dark-slide has been in use since the early days of calotype
paper negatives, and contains two plates separated by a blackened
metal plate; three of them usually form a set, the shutters being
numbered I to 6, the odd numbers on the opening side. Inner
frames can be used for smaller plates if desired. The slides should
fit easily into the camera and the shutters run smoothly out and
in.
They must be perfectly light-tight, the corner joints, the hinges
in the shutters, and the openings in the sides and top of the bookform slides are all weak points requiring occasional careful examination or protection by metal plates.
The shutters of dark-slides
are either jointed or solid and removable; the former is perhaps
the more convenient, but both forms may become liable to let in

used with some magazine and other cameras. They are arranged
to fit on the camera in place of the dark-slide and the plates are
changed automatically so that exposed plates are placed in
order successively at the back, a fresh plate going forward for
exposure and the number of the exposure being recorded at the same
time.
Studio cameras, for portraiture, are usually of the square bellows
type, of solid construction, to take large and heavy lenses; adjustable
from front and back with rack and pinion movements, to enable
long or short focus lenses to be used, with extra extension for copying or enlarging. They are generally fitted with repeating backs,
allowing two or more exposures to be made on one plate. The
backs are square or reversible, so that the plates can be used upright or lengthways, and are fitted with double swing movements
at the back. When single dark slides are used they are best fitted
with a flexible shutter to avoid jerking and movement of the
camera. For portraiture they are mounted on solid pillar stands,
being raised or lowered with an endless screw or rack-work, and
the table-top usually has vertical and horizontal angular movements. Large cameras with long extension for copying purposes
are made in many forms with special arrangements for the various
photo-mechanical processes, and are mounted on substantial
table-stands with screw adjustments for obtaining the various
motions above noted, and also a rectilinear traversing motion
All these stands should be absolutely rigid and free
right or left.
from tremor. Process cameras are, however, sometimes mounted,


PHOTOGRAPHY

Portable and field cameras include cameras of the Hare and Meagher types for outdoor work and general purposes on plates 15 in. X 20 in. or in smaller sizes, and for use on tripods in sizes of 15 in. X 4 in. to 24 in. X 31 in. For general purposes they are usually made with square bellows and folding tail-board, rather more substantially than those with conical bellows intended for outdoor work. These bellows are of many patterns, the plates of films or plates can be carried, changed, and exposed rapidly in succession, are convenient, but their use is limited and they are liable to get out of order.

The choice of a hand camera depends upon the circumstances in which it is to be used, and the purpose for which it is principally required. For general work and with the modern facilities for carrying and changing plates and films in daylight, the numerous folding hand or stand cameras for flat or roll films, with full adjustments, will be found most useful. Box or magazine cameras in which supply of light and cameras with focal plane shutters for specially rapid instantaneous work as noticed above. There are two types of light and dark cameras, especially adapted for hand cameras—those for single glass and dark cameras, and cut films, and the folding pocket Kodak or other roll-film cameras.

All of them is fixed in focus for all objects within a certain distance, in others it is adjusted by a focusing scale on the lens or an extending front. Some have a single magazine, others a double. Some take only glass plates, others plates or cut films. All of them are, however, self-contained and ready for immediate exposure. One of the earliest forms of single magazine cameras, still in use, as in the "Eureka" and "Yale," is the "bag," in which a supply of plates or films in sheaths, is kept in a magazine behind the camera, ready for exposure, the plates as exposed being lifted with the fingers into a bag or expanding chamber above the magazine and placed behind the rest of the plates at once. Some form the magazine are removable and replaceable by others. The arrangement is simple and effective, but the bag, usually made of soft leather or cloth, is liable to wear and puncture, and may make quite a number of exposures before it is kept in one recess and transferred successively after exposure to a second recess are more complicated, and many of them need the focus of the lens.
ingenious devices have been invented for effecting the change (fig. 5). Some forms are effective and popular on account of their compactness and readiness for immediate exposure, but there is always a risk of the mechanism failing, and care has to be taken in charging them to lay the plates true in their cases. The very handy binocular cameras, or photo-jumelles, of which the "Verascope" (fig. 6) is a type, are of this class, and have additional to be exposed when desired. Binocular hand cameras are also made on this principle, one compartment serving for focusing, the other holding lens and plates. Stereoscopic cameras are another form of twin-lens cameras, and are usually made for also taking single panoramic pictures.

In reflex cameras only one lens is necessary, though two are convenient, and can be used somewhat as in fig. 9. They generally consist of a cubical box camera containing a movable mirror facing the lens at an angle of 45° and throwing up the image projected on it to a horizontal focusing screen, on which it is viewed through a flexible hood which folds down in the upper part of the camera when not in use (fig. 10). In order to get the greatest rapidity of exposure a focal-plane shutter is generally fitted, and by a single movement of the release the mirror is smoothly lifted and the plate exposed simultaneously. They should be fitted with anastigmatic lenses working at large apertures for very rapid work. In some forms the lens is fixed, but usually there is a front bellows extension for focus-lens, with rising and falling front, to which swing motion may be given, a swing-back not being generally used with the focal plane shutter. In the "Ernex" camera E. J. Watson's invention, the mirror and focusing screen are separated, the objects being viewed, not on a ground-glass, but on the focusing screen of the camera, which is presented for this purpose. They may also have reversing or revolving backs for quickly changing the position of the plate. 5 in. X 4 in. and 3 in. X 4½ in. are the usual sizes of the plates, but larger and smaller sizes are also available. These cameras require the best workmanship and perfect mechanism for successful working and freedom from any jarring movement in releasing the shutter or mirror. The focusing screen must also be in accurate register with the focus of the lens on the plate. Those forms in which the image can also be viewed at the height of the eye, as in the Graflex (fig. 10), are preferable.

Although reflex cameras are rather heavy and bulky as hand cameras, they have many advantages over the fixed hand camera with finder and focusing scales for the purpose of the press photographer, the naturalist, and others, in observing and recording very rapid movements, and have come into very general use for such purposes. They permit the accurate focusing of a full-sized image on the ground-glass up to the moment of exposure, especially useful when lenses of long or short focus are required and when the rising or swing front is in use. The aspect of this image on the ground-glass is also a great aid in the selection and placing of the subject and in judging the exposure required for it. They practically have all the advantages of a stand camera and can be used as such on a stand for subjects requiring prolonged exposure. They are also coming into increasing use in studio work for portraits of children, &c. Their use and adjustments are discussed by G. E. Brown in the British Journal of Photography for 1909.

Panoramic Cameras.—Many so-called "panoramic" cameras have been introduced from time to time, among them T. Sutton's (1861), and J. R. Johnson's "Pantascopic" (1864), but did not come into general use till the use of curved surfaces of celluloid film enabled such cameras of convenient size and weight to be put on the market. They are on the same principle as one made by Von Möbius in 1845 for curved daguerreotype plates, and covering an angle of 150°. P. Mottard's "Cylindrographe" of 1889 was the first of the modern type. It consists of a semi-circular
PHOTOGRAPHY

APPARATUS

Camera, the front of it formed of light-proof cloth and the back by the curved flexible carried. The lens is fitted on a vertical axis, so that the nodal point of emergence remains motionless, and is revolved round by means of a handle worked by hand and carrying a viewing meter. The illumination of the glass faces of the perpendicularly slitting an adjustable vertical slit in a tube attached to the lens inside the box, and by altering the rate at which the lens is revolved. The pictures taken measure less than \(\frac{1}{100}\) of the apparatus folds together and is quite portable; it is fully described in Le Cylindrographe (Paris, 1889). The "Al-Vista" (1900) and the "Panoram Kodak" (1900) are on the same principle, but arranged as roll-holder hand cameras, in two sizes, carrying film for several exposures, 7 in. x 2 in. or 4 in. x 3 in. They have been made successively, and by means of a clock-spring the roller rotates rapidly over a half-circle when released. The angle of view is about \(\frac{1}{10}\) (figs. 11 and 12). The view is projected on a plane surface causing apparent distortion. This distortion, on account of the development of the camera, is, however, always remains slightly (Bull. Soc. Fr. d. Phot., 1891, p. 183). Commandant A. Dubreusse has improved on Moës's apparatus, by placing the lens vertically between two right-angled prisms, the upper of which receives the image and regulates it through the lens to the second prism. The image is projected by rotation of the system on the vertical axis, it is projected on to a cylindrical film through an angle of \(\frac{1}{2}\) (Ibid. 1906, p. 430; E. H., 1907, p. 97). The Perpingsith and Emmannion's "Kundhick" camera are also improved forms (E. J., 1906, p. 517).

Many early forms of panoramic cameras are described in B. J. A. 1892, p. 517. Colonel W. R. Stewart's "Panoram" (1893). A. Chevalier's "Photographic Plane Table" (1894). "Photo-Theodolite" (1894), and similar cameras with telescopes, levels and divided circles, are instruments of precision suitable for photographic surveying. Improved instruments for topographical surveying with an aerial-photographic apparatus, the specially worked out by Dr. C. V. De Morgan, and others, in his stereo-comparator (1903), are being practically developed, and much information regarding them will be found in papers by E. Dolezal and others in J. M. Eder's Jahrbiicher, 1903 to 1908; and R. W. Thome in Geographical Journal, 1908, 534.

Cameras for Three-Colour Photography.—Many forms of camera have been constructed for making the three negatives required for chromatic photography, which fall into two types: (1) those with a repeating back fitted with three colour-screens or filters—red, green and violet—through which the colour impressions are made successively with one lens upon a single colour-sensitive plate, as in tessellating apparatus; and (2) those in which the colour-screens are placed immediately in front of the sensitive plate in the repeating back, which is not the case with more recent form, by the same maker, the three images are taken on the sensitive plate with one lens, the colour being regulated by reflection of the light coming from the lens by plane mirrors on to the sensitive plate, and its filtration through the colour-screens in front of them. Many variations of this method have been proposed, in which reflecting or so-called "collophonic" pictures were obtained. A camera was described by W. Gamble (Ph. Jour. 1905, xlv. 3), the latter also by E. T. Butler (Ibid. p. 199). Sir W. de W. Abney has described three-colour cameras for landscape work in Ph. Jour. 1904, xliii. 81.

Enlarging Cameras.—These cameras vary in form, according to the nature of the illumination, but ordinarily consist of a double or triple extension bellows camera, with a holder for the negative placed in front of the apparatus, at one end, and for the sensitive plate at the other, the lens being placed on a fixed partition between the two. Some recent forms of "daylight enlargers" can be used as an ordinary camera. Other cheaper ones are on the fixed focus principle, and are arranged like a magic lantern, with a condenser, projecting an enlarged image on to a sensitive plate or paper fixed on an easel or screen. A simple arrangement for daylight enlarging is to fix a suitable camera on the tripod by a short front, with a light of a special, more studio stand tilted so that the image may be illuminated by the open sky.

Cinematographs.—Many special cameras and lenses have been introduced for taking on a large flexible film an extended series of still photographs of the successive phases of movements, and again projecting them on a screen so as to reproduce the scene, with an illusion of motion, in what are known as "living pictures," biographs, &c. As each photograph requires a certain minimum time to be exposed, and the film should have a certain small sequence of exposures, the rest, some means of regulating the intermittent exposures and keeping the film in position have to be adopted; and there are many different ways of doing it, either by a continuous or intermittent movement, such as winding the film from one roller to another. The films used are similar to the ordinary celluloid films, but in narrow bands from \(\frac{1}{4}\) in. to \(\frac{1}{2}\) in. in width, the length varying with the number of exposures required in the series. They are sometimes mounted on both sides, so that they may run true and have the necessary intermittent motion, the perforations fitting on to a sprocket wheel in connexion with the driving wheel and crank handle. Special films are made, 3 in. or \(\frac{1}{8}\) in. wide, the covering paper and large apertures \(\frac{1}{4}\) to \(\frac{1}{2}\), are prepared by the photographic processes, and several such are noted below. Absolute rigidity in the camera is essential. Special stands are made for the purpose, but it is tradi "Swincam" camera stand is made in such a way that the table is required for developing and fixing the exposed films. They are wound on large rollers supported over troughs containing the necessary solutions (see VENOMGRAPH). The mechanics arranged for this purpose by H. E. Hopwood, Living Pictures (1905), F. P. Low, Handbuch der praktischen Kineematographie (1907); K. W. Wolf-Czapak, Die Kineematographie (1908); G. Lindsay Johnson, Photographic Optics (1909); Eder's Jahrbiicher.

A method of cinematography in colour was introduced by G. A. Smith and C. Urban in 1908, the main features of it being the use of a film sensitive to all colour waves to the furthest red; superimposing the colour records by persistence of vision; the use of two or more records being interposed between the successive presentations; adaptation to existing cinematograph machinery and films. These conditions are fulfilled by the use, in place of the ordinary revolving shutter in front of the lens, a series of lights of a special, more rapidly revolving shutter divided into four sectors, one fitted with orange-red glass, another with bluish-green glass and two intermediate opaque sectors, so that at every revolution of the shutter each of the four sectors is illuminated separately. The former passes white and yellow, and then orange, scarlet to deepest red; whilst the latter passes white and yellow, green, blue-green, blue, all in proportion according to the red and green sensitive plates which are divided into four sectors, the former being illuminated by the white and yellow light, the latter by red and green light. The colour is given to the film by selecting the proper sector. The same shutter and colour screens are used for projection, some supplementary blue rays being added. The results are satisfactory and the method promises to be of great practical value for news, etc. (Jour. R. Phot. Soc., 1907).

Special cameras are made for various branches of scientific research in photo-micrography, photo-spectroscopy, astronomical photography, &c.
